A LADY residing in Ireland, whose name and address I have unluckily mislaid, sent me last autumn two plants under the above name. The plants have done very well, having come through the winter unprotected in the open border without harm, and are now in flower. This Paeony, which is not in the *Kew List*, is a very beautiful plant, and I should be glad to know its country of origin. It is about one foot high, the leaves alternate, on red footstalks, ternate, the leaflets lanceolate, 2½ to 3 inches long, the upper surface bronze green, shining as if burnished, the under surface and veins rich red. The flowers are cup-shaped, calyx ruddy-bronze, corolla clear light rose, enclosing crowded anthers of lemon-yellow, from which project the vivid crimson carpels. The blossom has a fruit-like odour, something between an Apple and a Plum. I am extremely grateful for so desirable an addition to our collection. *Herbert Maxwell, Monreith.*

[In *Index Kewensis* Paeonia Cambessedesii is given as a synonym of P. corallina.—EDS.]

CAMPANULA KEWENSIS.

THE charming little hybrid Campanula illustrated in fig. 89 originated in the rock garden at Kew in close proximity to its parents C. excisa and C. arvatica. The plant is intermediate in character, having the habit of the former, and bearing the open flowers of the latter parent. The wiry, branching stems are about 4 inches high, bear narrow, sparsely toothed leaves, and produce single flowers on terminal branches. The blooms are rather deeper in colour than those of C. arvatica. C. kewensis grows well in a moraine-like pocket, spreading, similar to its parents, by means of underground runners. The plant first flowered in June, 1916. *W. J.*

NOTICES OF BOOKS.

THE FLORA OF LORD HOWE ISLAND.*

LORD HOWE ISLAND is one of the many remote insular gems of the Southern Hemisphere clothed with a varied and beautiful vegetation. It is a mere speck in the ocean, estimated at five square miles in area, and it lies about 300 miles off the eastern coast of Australia in 31° 33′ S. latitude. The surface consists of three volcanic mountains, connected by flat ground, and rising to nearly 3,000 feet, with perpendicular cliffs on the seaside. The climate is equable, and warm-temperate, with an annual rainfall of about 50 inches, spread over the whole year, but most copious in summer.

The literature dealing with the flora dates from 1853, and includes a synopsis by the writer of the present work (*Transactions of the New Zealand Institute*, vol. xxix., 1896). This has been supplemented by J. H. Maiden and W. W. Watts. Mr. Oliver's work is more comprehensive, especially concerning the vegetation, the result of personal observation and investigation. He figures the anatomical structure of the leaves of the leading forest trees and classifies the plant formations; but what appeals more to the distant naturalist is his illustrations of the scenery embodying the prominent features in the vegetation of lowland and mountain. The pictures show the interior of lowland forest; the Great Banyan, Ficus columnaris; Moss Forest, on summit of Mount Gower; Howea Belmoreana in forest; Hedyscepe canterburyana, Howea Forsteriana, and Clinostigma Moorianum. All four of these Palms are more generally known in horticulture under the name of Kentia, and two of them, at least, are among the most popular and useful Palms for indoor and conservatory decoration. Mr Oliver classifies the woody vegetation of the island as follows:—

I. Forest. From sea-level to 600 metres. Climatic conditions normal. Trees 8–20 metres tall. Palms, Pandani, Tree-ferns. Lowland high forest Ficus columnaris, Howea Forsteriana. Upland high forest—Acialyptus Fullagari, Howea Belmoreana. Lowland low forest Hemicyclia australasica, Howea Forsteriana. Mountain low forest—Notelaea quadristaminea, Hedyscepe canterburyana, Pandanus Forsteri.

II. Moss forest. Mountain summit above 600 metres. Constant wind, with frequent rain and fog. Shrubs, Palms and Tree-ferns, 3—4 metres tall, with dense undergrowth of shrubs and ferns. Epiphytes abundant; ferns, mosses, and lichens. Dracophyllum Fitzgeraldii, Clinostigma Moorianum, Cyathea brevipinna.

III. Scrub. Edge of forest along sea coast and on exposed ridges. Constant wind bearing salt spray along the coast. Shrubs 1–2 metres tall; few trailing and herbaceous plants. Coastal scrub Ochrosia elliptica, Lagunaria Patersonii, Myoporum insulare, Melaleuca ericifolia, Cassinia tenuifolia. Hill scrub Dodonaea viscosa, Hemicyclia australasica, Raponea platystigma.

The marine formations offer no striking features, Avicennia officinalis and Aegiceras corniculatum constituting the Mangrove element; whilst Salicornia australis is represented by a few patches. Full details of the composition of the vegetation of the various formations are given by the author. Of the 169 genera of vascular plants represented in the island, four are endemic, namely: Hedyscepe and Howea (Palmae), Negria (Cyrtandreae), and Colmeroa (Saxifragaceae). Out of a total of 209 species recorded by Oliver, 70 are endemic. Ferns number 45 species, belonging to 25 genera, representing the principal types of the Filicales, and including four endemic Tree-ferns and no fewer than seven species of the Hymenophylleae. Petaloid monocots are rare, but there are five Orchids belonging to four genera. The endemic Moraea Robinsoniana "occurs from sea-level to the summit of Mount Gower, in scrub on cliffs and in rocky places; always in exposed places." Taken as a whole, Mr. Oliver's account of the flora of the remote Howe Island is a most instructive contribution to the subject of insular floras. *W. Botting Hemsley, Henfield.*

* "The Flora and Vegetation of Lord Howe Island." By W. R. B. Oliver. From *Transactions of the New Zealand Institute* Vol. XLIX., 1916, pp. 94-161, plates x.-xvi., with a few anatomical figures in the text. Issued July 6, 1917. Wellington, N.Z.: Marcus F. Marks, Government Printer.)

FIG. 89.—CAMPANULA KEWENSIS. FLOWERS PURPLISH-BLUE.

HARDY FLOWER BORDER.

VESICARIA UTRICULATA.

VESICARIA UTRICULATA, the Bladder Pod, is a desirable plant for the flower border or large rock garden. In the colour of the flowers and the general appearance it is like the golden Wallflower, but is a distinct and pleasing plant. It grows about one foot or 18 inches high, has narrow leaves and arching stems surmounted by clusters of golden Wallflower-like blooms. In the rock garden it should be planted in full exposure to the sun, and it succeeds well in a dry soil. An interesting feature of this Vesicaria is revealed after the flowers wither, for the seeds are enclosed in a small, bladder-like pod, hence the name of "Bladder Pod." The species is figured in Silithorpe and Smith's *Flora Graeca*, t. 627. Although the plant is a hardy perennial, occasional renewal of the stock from seeds or cuttings is desirable. Seedlings raised from seed sown not later than June bloom the following year. Self-sown seedlings occasionally appear near established plants. *S. Arnott.*

WART DISEASE.

THE issue of a new Wart Disease Order marks another stage in the control of a disease which threatened at one time to ruin the Potato industry in this country. Before the war it had stopped the bulk of our export trade, and every foreign Government hastened to prohibit or hinder the import of Potatos which might be affected with Wart Disease or "Black Scab," as it was commonly called. The disease makes its appearance mainly in the tubers. A tuber attacked by the disease is illustrated in fig. 90; but the stems, leaves, and even the flower may be attacked if the fungus can obtain an entrance when the part lies on the soil.

As a result of the discovery of immune varieties and the failure of remedies—whether chemical or mechanical—together with the fact that the spores lie in the soil for at least nine or ten years, the Board of Agriculture resolved to endeavour to control the spread of the disease by a system of licensing resistant varieties: they have scheduled all places known to be infected, and allowed only such varieties to be planted there. This system worked well enough for a limited number of cases, but now that the known cases run into thousands, and cover a very large acreage, they have decided to deal with the cases on a simpler basis.

The new Order, which comes into force on June 1, makes it illegal to plant any but approved immune varieties in an infected area. This area may be of any size, and the term may cover private garden, borough, parish, or even a county. All infected premises and areas already declared are included, and fresh areas will be certified from time to time. At the rate the disease is spreading—owing to the scarcity of "seed" and consequent use as "seed" of anything in the shape of a Potato, it made rapid strides last year—the pest will soon be prevalent all over the country, and ordinary varieties of Potato, which are largely susceptible, may soon disappear from cultivation. The disease has been known in out-of-the-way places for some forty years, and probably longer.

It is commonly stated that it is only a pest of cottage gardens and allotments, but infected fields are common in Lancashire, Cheshire, Shropshire, Staffordshire, and elsewhere. At present little is known of its presence in the East and South, but each year fresh cases are reported in these districts, and, as few of the Potato growing areas of the North are free, it is only a question of time before the whole country is infected.

Another section of the Order will affect all growers of the approved immune varieties if they sell "seed," even to a neighbour, as no one is allowed to sell such Potatos for planting except to a dealer in seed Potatos, unless he is authorised to do so by a licence granted by the Board. The object of this clause is that such Potatos may be inspected as being true to name and free from rogues, and thus the further spread of disease owing to an intermixture of varieties or wrong naming may be prevented.

The question of the supply of immune "seed" is receiving attention, and sufficient quantities will doubtless be available next spring. The number of these varieties now totals over sixty, many of them being good croppers and of excellent quality. Some, for example, Great Scot, King George, Lochar, Abundance, Langworthy, and Golden Wonder are well known, and others, such as Rector, Majestic, and Dominion have a future before them. Unfortunately, very few first earlies are immune, and these not the best sorts. It is of the utmost importance that good varieties should be available, and many raisers are engaged on this work; several promising varieties have been tested at Ormskirk, and have come through their first season satisfactorily.

Much work of a more scientific nature remains to be done, and no one has yet solved the mystery of one variety being immune, while another, to all intents and purposes similar, is very susceptible to the disease. There is no common characteristic amongst the varieties which so far has yielded any clue. Many of the immune sorts have white flesh and white flowers, but others have yellow flesh and coloured flowers. The haulms differ in growth and habit as much as susceptible varieties do. It is not a question, as some people think, of the varieties having stamina owing to fresh crosses, as many new seedlings are badly attacked, while old varieties, like Abundance and Schoolmaster, still resist, although, in growers' estimation, they have "run out." Up to the present, no variety once established as "immune" has broken down. From time to time Great Scot is reported as having the disease, but investigation shows that it is rogues, usually Arran Chief, which are affected. Snowdrop had to be withdrawn from the Board's list, as it so often yielded diseased plants, but this has been proved to be due to an admixture of a yellow fleshed

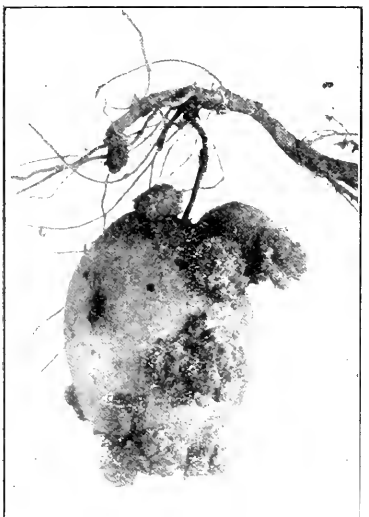

FIG. 90.—POTATO TUBER AFFECTED WITH WART DISEASE.

variety, probably Duke of York, with most of the stocks. Both in this and also in Witch Hill, if sets are cut and yellow-flesh tubers are discarded, the resulting plants from white-flesh sets are free from disease. The immunity is probably due to some chemical action of the sap, or possibly to something in the nature of a toxin. Another point to be cleared up is the condition of the sporangia which remain so long in the soil. Do they remain merely as sporangia and only germinate when acted on by some secretion from the Potato? Do immunes fail to yield such a secretion? Or do they germinate as some spores do and encyst again later if they fail to find a host? These and many other questions can only be cleared up by careful research, preferably by a bio-chemist in conjunction with a botanist, assisted by the Board's outdoor officers, who have been engaged in the work for some time. These would approach the question from different standpoints, and would endeavour to work out the complete life history of Synchitrium endobioticum, as the causal fungus is called, in the hope that some weak point in the life history may be found and the disease stamped out. *G. C. Gough.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey

CELERY.—If the trenches for Celery are not already prepared they should be dug forthwith, then, when the plants are sufficiently hardened they may be at once transferred to their final quarters. Prepare shallow trenches 15 inches wide and one foot deep for early rows, using a liberal amount of rotten manure in the trench after first forking up the bottom soil. Cover the manure with a layer about 4 inches deep of soil and allow it to settle for a few days before planting. Do not allow the plants to remain in the boxes in which they were transplanted too long, or they will become stunted and yellow. Plant firmly and carefully, using a trowel, as the roots are easily damaged. Water the plants copiously immediately after planting them, and shade them from bright sunshine for a few days. Allow a space of 3 feet between single early rows and 4 feet 6 inches between double rows, increasing the width of the trench in the latter case to 2 feet. On well drained soils it is almost impossible to over-water Celery. Lightly dust the plants with soot once or twice a week, especially where Celery fly is troublesome, and feed the roots freely with diluted liquid manure as the plants advance in growth.

LETTUCE.—Great care and attention is necessary to maintain a regular supply of Lettuces. Small sowings of both the Cabbage and Cos kinds should be made every week or ten days. During the summer no place is better for growing good Lettuces than on the ridges of Celery trenches. Cos Lettuce is generally more in demand than the Cabbage kind, and two rows can be planted on top of each ridge at one foot apart each way. Water the plants copiously after planting, and keep a sharp watch for slugs, especially during showery weather.

PEAS.—Make further sowing of Peas of such varieties as Duke of Albany and Alderman, following with those recommended in the calendar of March 29. Sow the seed thinly, and allow plenty of room between the rows, for with abundant space the plants give more pods and better Peas. Early plants which are coming into flower, and those of mid-season varieties, must never be allowed to get dry at the roots.

TOMATOS.—Plants intended for cropping in the open must not become pot-bound or suffer a check from any other cause. If protection can be given, plants intended for growing against warm walls may be planted out from this date onward. Pot on later plants if necessary, and give them such treatment as will make them sturdy. Let them be well hardened in readiness for planting out in the open quarters the first week in June.

CABBAGES.—Continue the planting of early varieties of Cabbage. Plant closely in the rows, and do not allow more than 18 inches between the rows, as moderate-sized heads are the most serviceable. Economy of space should always be considered without unduly crowding the plants. Do not allow ground to be vacant many days without cropping it afresh.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

CARNATIONS.—Some of the old Carnation plants should be removed from the flowering house to make room for those which have been propagated this season. These old plants will produce plenty of flowers for some time to come if their requirements are regularly attended to. They may either be placed closely together in a cool house or plunged out-of-doors at the foot of a south wall. Keep them liberally supplied with water, and use stimulants two or three times a week. Grow the young plants in a position near to the roof-glass, and let them have plenty of room. The earliest-rooted plants are

ready for their final shift into pots 7 inches in diameter. A compost consisting of good fibrous loam, crushed brick rubble, wood-ash, crushed bones, and sharp sand, forms a suitable rooting medium for Carnations. The soil should be mixed several days before it is required for use. Pot firmly. Souvenir de la Malmaison Carnations need watering and feeding more liberally, as the flower-spikes are developing. Remove all side buds and place a neat stake to each growth. If it is desired to hasten some of the plants into flower, a few may be placed in a warm house.

ROSE FORTUNE'S YELLOW.—It would be difficult to find a more useful or beautiful Rose for growing in a cool, lofty structure than Fortune's Yellow. When once established its cultural requirements are of the simplest. Our latest plants have just passed out of flower, and all the old flowering wood has been cut hard back. They are already sending out strong young shoots. These will be thinned out and trained over wires about 15 inches apart. During the growing season the roots are liberally watered with diluted farmyard drainings, and, in addition to this, the rooting area is covered with 2 or 3 inches of well-decomposed horse or cow manure. During the winter water must be given sparingly, but the roots must not be allowed to become excessively dry.

GREENHOUSE CLIMBERS.—Careful attention must be paid to the thinning and training of the young growths of climbers. Some of the more vigorous subjects may require somewhat severe treatment in this respect, or they will smother their weaker growing neighbours. Plants growing in restricted borders need copious supplies of water while in active growth, and this must be supplemented occasionally by some form of stimulant. Keep a careful look-out for aphis, and fumigate the house as soon as this pest is perceived.

THE FLOWER GARDEN

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

BULBOUS PLANTS.—Muscari Botryoides, Scilla præcox and varieties; S. italica, Crocuses, Snowdrops, Chionodoxas, Erythroniums, and Winter Aconite are all common but beautiful bulbous plants that may be transplanted now without doing much harm to the plants. They are all beautiful objects in grassland, and require no other encouragement to grow than just to notch places in the turf with a spade, insert the bulbs, keeping the foliage intact, and then leave them to themselves.

WILD ORCHISES.—Orchis mascula is at present in flower, and where it is to be found growing wild it is worth while going with trowel and basket on an excursion to secure a supply of the finest forms. The plant grows best in a heavy loam, and by careful lifting nearly the whole of the roots may be secured, together with enough of its native soil to enable them to grow without a serious check. Once established in a shaded part of the rockery I find that this Orchid increases from self-sown seeds. There are some pretty wild forms, and apart from their beauty the plant has a sentimental interest from its being the "Dead Man's Fingers," and possessing other common names, almost all forgotten now.

TRANSPLANTING SHRUBS.—Certain shrubs and trees succeed better planted at this time than at any other season of the year. Such are Hollies, Yews, and Evergreen Oaks. To have perfect success they must be caught just before the buds begin to break, and, in addition, large plants should have been prepared for lifting by root-pruning them previously. The time for transplanting must obviously vary to some extent, according to the locality. Should the soil be dry it will repay the labour to water the plants a short time before removal, and the work should always be done in dull weather. The hole for the reception of the ball of roots and earth should be fairly large, and firm soil compression is most important. Very large specimens require three stakes driven in at equal distances outside the ball and meeting together at the plant, each forming a sharp angle. For smaller plants one stake is sufficient driven in, in a similar manner, in the part opposite that from which the highest winds prevail. Last year about this time I transplanted some moderately large shrubs and Conifers with very little soil attached to the roots. The plants were profusely watered and dry soil added as a mulch; every one succeeded, even a common Oak.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN Bart., Gatton Park, Reigate.

DENDROBIUM PHALÆNOPSIS SCHROEDERIANUM.—Plants of this Orchid and its varieties are developing new growths, and any requiring fresh rooting materials should receive attention in this respect as soon as roots appear at their base. The plants will grow equally well either suspended from the roof-rafters or on the stage. An important detail in their cultivation is to place them near the roof-glass, in order that they may obtain all the light available. If it is intended to suspend the plants they should be grown in shallow pans furnished with wire handles. Plants that are to be grown on the stage are best grown in pots. It is not advisable to repot plants that were potted last season. The receptacles for any that are repotted should not be larger than is necessary to just hold them, as the plants do not require too much rooting space. In repotting, about half fill the pots with clean crocks for drainage, and arrange the plant so that the growth is level with the rim of the pot; make it secure by tying the pseudo-bulbs to a neat stick. Specimens grown in pans should be secured to the wire handles. Water the plants carefully until the young roots have made satisfactory growth, when moisture should be afforded liberally. During its season of active growth this Orchid requires a considerable amount of heat and atmospheric moisture, and should be shaded from bright sunlight for a few hours during the middle of the day. Dendrobium bigibbum and D. superbiens are closely allied species, and require similar treatment.

CHYSIS.—Chysis bractescens, C. aurea, C. Sedenii, C. Limminghii and others may require repotting after they have passed out of flower. They are best grown in suspended shallow pans. Those that have sufficient pot-room for another season's growth need not be disturbed if the soil is in good condition. Those of which the soil is sour, or that require more root-space, should be repotted. Ample drainage should be provided; a suitable rooting medium is three parts Osmunda fibre or A1 fibre one part Sphagnum moss (both chopped rather short), and a liberal sprinkling of crushed crocks. Mix the materials well together. Pot firmly, and keep the base of the plants a little below the rim of the pan. The plants should be suspended from the roof-rafters in the lightest position in the intermediate house, and should be sprayed frequently, wetting the undersides as well as the upper surfaces of the leaves in order to prevent attacks of red spider and yellow thrips.

THE HARDY FRUIT GARDEN

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

ALPINE STRAWBERRIES.—Young plants of Alpine Strawberries that were raised from seed sown last season have made good progress. They are showing their first flower-spikes, and as this batch will be wanted to supply ripe fruit in late August and September, these early flower trusses should be picked off, and it will be necessary to continue to remove the blossoms until after the first week of July. The ground between the plants should be kept well stirred, and no runners allowed to grow. If hoeing be persisted in the plants should not stand in need of water if the weather sets in dry. I have not, so far, been able to secure my usual packets of seed for sowing this spring. As this seed is generally saved on the Continent, the explanation is not far to seek. I hope, however, soon to receive it, and no time then will be lost in sowing it. As a safeguard, however, I propose to take runners from last year's seedling plants. These will be pricked off in frames at once, and treated like young Celery plants. The plants forming the beds that are intended for the first crop are showing well for flower, and promise to give ripe fruit by the last week in June. Our beds have not received the usual looking this season, but as they were well cared for last year no harm should accrue, although we shall have to be careful where we step when picking the fruit, as the ground is a mass of runners. The beds should receive a dusting with lime to deter slugs.

PERPETUAL STRAWBERRIES.—I have previously advised the making of new plantations of perpetual fruiting Strawberries in the early spring rather than the late summer. The plants should now be growing freely; remove any adventitious spikes as soon as they show. If a few runners appear fairly early let these be pegged down in the rows; one at least may be so treated between each crown, or crowns, if these were planted as triplets. Keep the ground between the rows well stirred at all times.

CURRANTS AND OTHER BUSH FRUITS.—There may not be much possibility of insect pests attacking bush fruits just yet, but one never can be quite certain when an attack will begin. On both Red and White Currants, as well as Gooseberries, caterpillars may soon be expected to cause damage. The pests should always be combatted early, and a weak insecticide is usually sufficient to destroy them. For big bud in Black Currants some growers advise a stronger specific at this season of the year. Keep a sharp watch if there be any suspicion of Gooseberry mildew, and endeavour to stamp out the disease as soon as possible. I have not had to deal with this pest, but if I did I should at once use lime-sulphur spray.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to Mrs DEMPSTER, Keele Hall, Newcastle, Staffordshire.

LATE VINES.—Tie in the young growths of late Vines carefully and gradually, or they will break away at the base, especially in the case of strong growing varieties of the Black Alicante type. Keep insect pests in check by damping the paths and borders; this should provide sufficient moisture to maintain healthy growth without much syringing. A little extra warmth in the hot water pipes may be needed if cold, dull weather prevails. When the Vines are in flower, keep the atmosphere dry, and allow a little air to enter by the top ventilators at night, to prevent accumulations of moisture and to assist the setting of the fruits. Thin the bunches in the early stages, and select the best placed medium sized bunches for the crop. Let the night temperature for Black Alicante be 65°, and for Muscats 5° higher.

UNHEATED VINERIES.—The scarcity of labour and the difficulty of obtaining fuel will no doubt compel some growers this year to dispense with fire-heat, and rely on sun-heat. Some years ago I had an unheated vinery under my charge on the West Coast, planted with Foster's Seedling, Buckland's Sweetwater, and Black Hamburgh Grapes. The Vines produced excellent crops and finished well. Syringing was entirely dispensed with, sufficient moisture being created by damping the paths and bare spaces. When growth was active the house was ventilated early to prevent scalding, a very necessary precaution when the foliage is wet with condensed moisture. The house was damped and closed early in the afternoon to conserve the sun-heat. Disbudding, pinching the shoots, tying the laterals, thinning, mulching, and feeding were carried out exactly the same as in the heated structures. In some unheated vineries mildew is likely to make its appearance, and must be checked in the early stages, for the fungus spreads rapidly, and may easily ruin the crop.

YOUNG VINES.—Vines struck from eyes early in the year should now be quite ready for shifting into larger pots. These young Vines may be planted out in prepared borders with excellent results. Care must be taken not to injure the young, fibrous roots, and a thin shading over the glass is advisable until the plants are established. The syringe should be used on fine mornings, and again when the house is closed, to ensure sufficient atmospheric moisture. The laterals should be closely pinched, and the leaders stopped when they have made 5 or 6 feet of growth.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 54.2.

ACTUAL TEMPERATURE:—*Gardeners' Chronicle* Office, 41, Wellington Street, Covent Garden, London, *Thursday*, May 16, 10 a.m. Rain .29.9; temp. 72°. Weather Sunshine.

Firewood and Faggots in War Time.

The present high price of coke and coal has had a marked effect on the consumption of firewood. As to which kind of timber is the best for use as firewood there is a great diversity of opinion, but probably in nine cases out of ten, Oak, Ash, and Beech, among our commonly cultivated trees, would be placed near the top of the list. The age and quality have a great deal to do with the heating properties of any wood, such as is old and thoroughly matured having greater lasting and heating properties than young, sappy timber. Slow-grown wood is preferable to that of rapid growth. Decayed or decaying timber makes poor firewood, as also does such as contains a quantity of sapwood. Some woods, such as the Ash and Plane, burn well in a green state; others must be seasoned or dry before use.

Irrespective altogether of the price or the quantities in which they can be procured, the timbers of some of the rarer trees not only burn most freely, but give out the greatest heat. Yew, when properly seasoned, approaches more nearly to coal than any other home-grown wood, both for heat-giving and lasting properties. It burns slowly, gives out a fierce heat, throws out no sparks, and is comparatively clean. Yew-wood should be felled for at least two years before it is used for firewood. The use of Hawthorn as firewood is proverbial, and in conjunction with Apple and Pear wood is greatly valued. It burns very slowly and almost without smoke, producing a great amount of heat. Hazelwood burns well, and is highly prized where it can be obtained in plenty.

Taking all in all, we are, however, inclined to place the Beech in the front rank as firewood. It is hard and lasting, gives out an even heat, and has the additional recommendation of being readily procured at a moderate price and easily split into logs. Oak, where it can be cut from seasoned timber, is hard to beat, though the smoke is bad for the throat. When the draught is perfect and the smoke finds its exit by the chimney there is little to complain of in Oak as firewood.

Ash is a very quick burner, even when green; and Elm, though a "dour" burner, is very lasting, and when thoroughly alight makes a pleasant fire. Few home-grown timbers, however, burn so brightly as winter-felled and partially seasoned Plane; indeed, for a lively fire that of the Eastern Plane has perhaps no equal, but it is a scarce wood in England. Pine wood makes a quick fire on account of the resin it contains, but the sparking is dangerous. Scots Fir, when old and resin-stained, makes a most desirable fire on a winter's night, and blazes with a glowing cheerfulness that finds a match in no other home-grown timber. Wood obtained from the Irish peat bogs is valuable, and sells at a high price. When used as firewood, the timber of Lawson's Cypress gives off a delicious fragrance, and is highly valued on that account. Chestnut is not a desirable firewood; indeed, as a fire resister it has no equal in the category of native woods. Birch burns quickly without giving much heat. Willow is to be recommended, but Poplar is somewhat objectionable. The addition of a few pieces of coal to a fire of such timbers as the Elm, Sycamore and Poplar, and, in fact, all timbers when in a green state, greatly improves their burning properties. Cedar wood burns with a pleasant fragrance, but is dangerous owing to its sparks.

The treatment of firewood rarely receives proper attention. It should be carefully stacked and protected from the weather for at least a year. Any cost that this may entail will be amply repaid by the increased value of the fuel. If a suitable building is not at hand, the wood stack should be thatched either with reeds or Birch branches; and the same applies to faggots, both large and small. Faggots are as easily built into a stack as sheaves of corn, whilst firewood cut into 3-feet lengths occasions little trouble in building into a neat pile for seasoning. The age and dryness of wood has much to do with its burning properties, and timber that has become rotten by undue exposure in damp situations makes poor firewood.

In Kent and around London generally firewood is usually stacked and sold by the cord, which measures, according to local custom, 14 feet long, 3 feet broad, and 3 feet high, or 8 feet long, 4 feet broad, and 4 feet high. A cord of wood, about 2 tons in weight, will make 1,000 billets of firewood size. The price of a cord of firewood varies greatly with the district, accessibility, quality and demand, and has gone up fully 25 per cent. during the past two years. On an estate in Kent, twelve miles from London, the selling price before the war was 10s. per cord, but it is now 15s., and even at this figure the demand is greater than the supply. About 5s. per cartload is the usual price for rough firewood.

Large faggots for kiln and other purposes, 3 feet long and 24 inches in circumference when bound up, vary from 10s. to 15s. per 100, and small faggots, called "pimps" in the counties bordering London, which a year ago could be bought at 3s. 6d. per 100, now fetch 4s. 6d. and upwards. Before the war, owing to the making of faggots by pauper labour out of cheap foreign batten ends, home-made faggots for fire-lighting had decreased considerably in value.

That a very considerable quantity of the produce of our land woods, in the shape of rough trees and branches, is annually consumed for fire-lighting and fuel is not sufficiently recognised except by those who are directly connected with the trade. Returns to hand from the London firewood dealers alone show that the quantity is much greater than would be supposed, and the normal trade has been much increased by the exigencies of the war. Vast quantities of firewood are being sent to France and Flanders, in addition to charcoal and fire-lighters, with the result that there is a dearth of all these fuels at home. In many of the suburbs of London, indeed, it is impossible to purchase firewood of any kind, and much inconvenience is the result, especially as the many forms of fire-lighters are becoming more and more rare.

In ordinary times faggots and firewood are sent to the London market ready for use, the latter being bound up in bundles of the required size and the former cut into billets ready for the fire. Large faggots, or "bavins," as they are called in Kent, have also a ready market, and are used for kiln purposes.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Fellows of the Royal Horticultural Society will be held on the 28th inst. in the Drill Hall, Buckingham Gate, Westminster.

BIRMINGHAM ALLOTMENTS.—A memorandum issued by the Chief Officer of the Birmingham Parks (Mr. W. H. MORTER), contains particulars of the allotment movement in that city, and of the success which has attended the efforts of the municipality to increase the food supply. Immediately after the Government had issued the first Cultivation of Lands Order in December, 1916, the Council made over their powers and the work of administration to the Parks Committee. This Committee set about finding suitable land, but it was not until the issue of the new Order, in February, 1917, that matters progressed quite satisfactorily. High rents had at first frequently been asked, and the new Order (containing the provision that no higher rents should be paid than were previously obtainable for the land) gave the municipality exactly the power it needed. The ground obtained was divided into thirty areas, and an instructor appointed for each. In the early months of 1917 the demand for plots was overwhelming. It had been expected that the provision of about two thousand plots would meet the demand, and all the land taken early in 1917 was laid out in 400-yard plots. In the four months from January to April some 650 acres of land had been procured, and 6,250 plots of 400 yards each let to applicants at 10s. per plot. Arrangements were made with the leading seedsmen of

the city for the supply of seeds at a reduced rate to the allotment holders, and with ironmongers for the provision of tools. Spraying machines were purchased by the Parks Committee, together with the necessary materials; the materials were sold to applicants at cost price, and the machines let on hire for a nominal sum. The financial details of the scheme are as follows:—

Rents received from 6,289 plot holders, £3,118 17s. 3d. Approximate expenditure for the year:—Salaries and wages, £752 12s. 3d.; rent, rates and taxes, £1,451 4s.; fencing and pegs, £736 3s 10d.; printing, stationery, and advertising, £116 15s.; miscellaneous expenses, £203 15s 3d; law and professional charges, £79 7s 6d; stamp duty £116 15s; compensation, £234 11s 11d £5,751 4s. 9d.

In order to encourage the allotment holders, an exhibition was held in the Town Hall on November 6 and 7, and was a great success. Regarding 1918, Mr. MORTER reports that almost all the allotment holders of 1917 have again taken up their plots, but, owing to the fact that the cost of labour and materials has increased during the past season by 40 per cent., it has been found imperative to reduce the size of the plots from 400 yards to 320 yards each.

PRESENTATION TO A GARDENER. On Friday, the 10th inst., the Bath Gardeners' Association made a presentation of a cheque and an illuminated address to Mr. W. TAYLOR, a veteran gardener residing at Bath. In the words of the address, the presentation was made "by the members of the Association as a token of esteem and regard, and in appreciation of the valuable services rendered to the Society since its formation in 1903, and particularly during the last session."

LAELIO-CATTLEYA J. F. BIRKBECK FOWLER'S VARIETY.—Forms of this cross between Cattleya Mendelii and Laelio-Cattleya Henry Greenwood (L.-C. Schilleriana × C. Hardyana) have been exhibited, notably by the late Sir FREDERICK WIGAN, at the Temple Show, May, 1905. The varieties were, however, never deemed worthy of an award by the R.H.S. Orchid Committee until, on March 30, 1915, the variety illustrated in fig. 91, shown by the late GURNEY FOWLER, Esq., was awarded a First-class Certificate. Nothing comparable to the variety has since appeared, and it may be concluded that the plant is one of those abnormally fine forms which occasionally appear to reward the raiser. The flowers, which are large and of fine shape, have white sepals and petals, slightly tinged with pink. The large labellum is ruby-crimson with gold lines from the base to the orange-shaded centre. At the sale of the Brackenhurst collection the plant was acquired by Sir JEREMIAH COLMAN, Bart., whose gardener, Mr. J. COTTER, was accorded a Cultural Commendation for the fine appearance of the plant at the Royal Horticultural Society's meeting on the 7th inst.

SUPERPHOSPHATES. The Minister of Munitions hereby orders as follows:—1. As on and from the date of this Order until further notice, the maximum prices to be charged or paid for superphosphate sold or purchased in quantities of 14 lbs. and over but less than 2 cwts. for delivery ex vendor's store or shop, or ex warehouse, railway goods yard or public wharf, shall be the prices specified in the Schedule to the Order relating to superphosphates made by the Minister of Munitions on August 20, 1917, with the addition of the following amounts, according to the quantity of superphosphate included in the sale or purchase, namely:—Quantity sold or purchased and additional price authorised: 1 cwt. and over but less than 2 cwts., 2s. per cwt.; 28 lbs. and over but less than 1 cwt., 3s. per cwt.; 14 lbs. and over but less than 28 lbs., 4s. per cwt.; and there shall be no restrictions on the price to be charged or paid for superphosphates sold or purchased in less quantities than 14 lbs. for delivery as aforesaid. 2. The foregoing provisions shall have effect as and by way of amendment of paragraph (c) of clause 1 of the said Order of August 20, 1917. And paragraph (d) of clause 1 and clauses 2 and 3 of the said Order shall henceforth apply and have effect as though the additional prices authorised by paragraph 1 of this Order had originally been authorised by paragraph (c) of clause 1 of the said Order of August 20, 1917. 3. This Order may be cited as the Superphosphates (Amendment) Order,

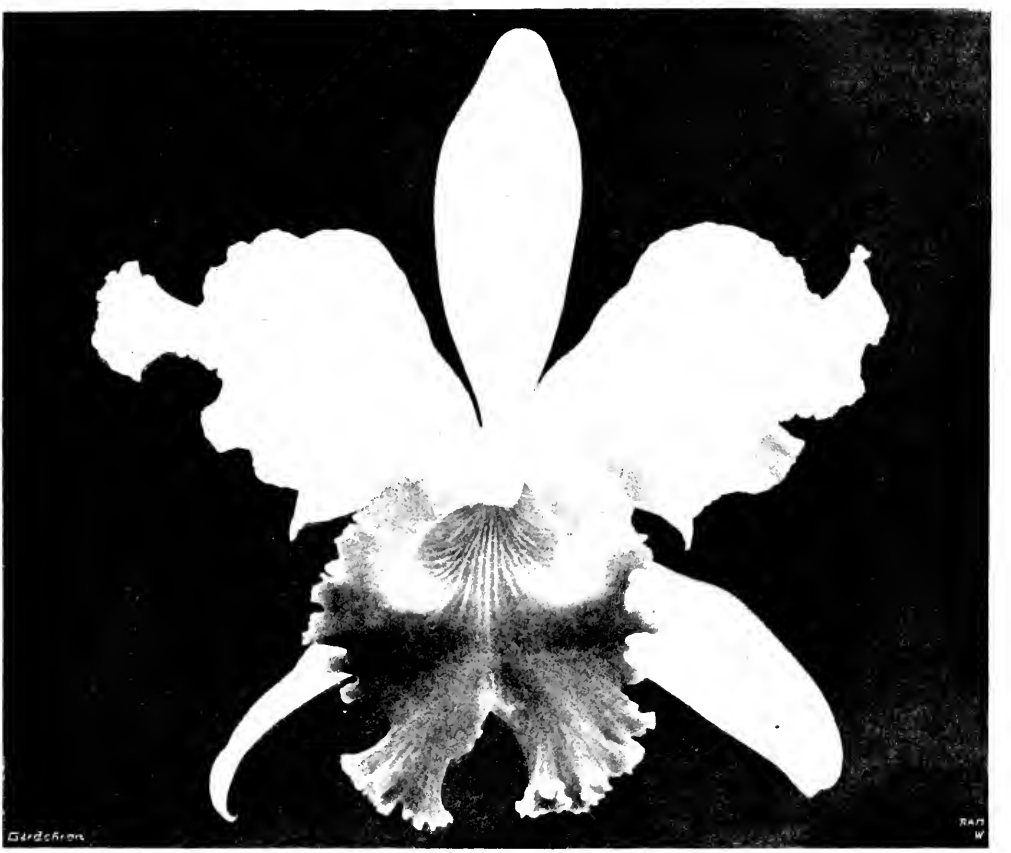

FIG. 91.—LAELIO-CATTLEYA J. F. BIRKBECK FOWLER'S VAR. THREE-QUARTERS NATURAL SIZE.
SEPALS AND PETALS WHITE, WITH BLUSH TINT, LABELLUM RUBY CRIMSON WITH A GOLDEN LINES TO THE ORANGE-SHADED CENTRE

1918. Note.—All applications in reference to this Order should be addressed to the Director of Acid Supplies, Ministry of Munitions, Explosives Supply Department, Storey's Gate, Westminster, and marked "Fertilisers."

GARDENERS AND SUPPLEMENTARY RATIONS.—The Ministry of Food has informed the British Gardeners' Association that gardeners are included in the list of those entitled to the supplementary ration, and will be graded under class E. Enquiries on the subject should be addressed to the Local Food Offices.

AMERICAN GOOSEBERRY MILDEW.—Growers of Gooseberries are reminded by the Board of Agriculture that, though no objection is raised to the dispatch of slightly affected berries to a jam factory in sacks or non returnable receptacles (as the mildew does not render the food unfit for consumption), yet, with the object of preventing the spread of the disease by means of infected baskets, it has been made an offence to sell or offer for sale in a market or shop any Gooseberries affected with American Gooseberry mildew.

GERMAN PRISONERS ON THE LAND.—The agricultural correspondent of the *Daily Telegraph* remarks that "the farming community has been vividly impressed with the excellent work that is being accomplished by German prisoners whose services have been utilised on the land. The almost unanimous verdict of the farmer able to judge is that the German prisoner is 'thorough' in his agricultural work. As for cleaning land, and getting it into goodly appearance, many farmers testify that the German (and Austrian) prisoner has done excellent work. The cry is for still more men to be used in the countless odd jobs necessary in agriculture. There is existing the machinery for putting far more prisoners of war on the land than there are at the moment. Some farmers have complained that the wages paid to Germans are too high: they are ruled by the current local rate, subject to a deduction of 15s. per week for board and lodging—but with British labourers growing fewer it would be better for agriculture if even more men were liberated from the German camps or agricultural depôts already instituted. Clearing ditches, laying drains, carting roots, cutting logs, threshing, and ploughing, are farm work in which the German prisoner excels. Farmers who have had the assistance of prisoners formerly used to agricultural duties have loudly proclaimed that their land was never so clean as it is at the moment."

COPPER SULPHATE FOR POTATO SPRAYING.—The maximum price fixed by the Government for copper sulphate in sales of not less than one ton for delivery from May to August by makers, free on rail, is £52 per ton. The maximum prices in the case of sales for delivery ex vendor's store, shop, or ex warehouse, railway goods yard, or public wharf, are:—2 cwts and over, 56s per cwt.; 56 lbs but less than 2 cwts., 58s. per cwt; 28 lbs. but less than 56 lbs., 60s. per cwt.; 8 lbs. but less than 28 lbs., 7d. per lb.; 4 lbs but less than 8 lbs., 8d per lb.; 1 lb but less than 4 lbs., 9d. per lb. The cost of transport to consumer's premises may be added to these prices, which are nett prompt cash for copper sulphate of standard quality, i.e., not less than 98 per cent. purity. Orders should be placed at once with local agricultural merchants, wholesale chemists, or ironmongers. If any difficulty is experienced in obtaining supplies, growers should communicate with the Food Production Department.

ON INCREASED FOOD PRODUCTION.

LEEKS.

I NEARLY gave up planting Leeks in deep, wide, dibbed holes, on account of gritty products on the table, but I find conclusively that any grittiness is entirely the fault of the cook. Hence I continue to use the method. The chief point is to use a good tool; mine is made from an old pickaxe handle with a foot and a half long cross handle, the wider part of the shaft tapered off to a moderately sharp cone of oval section. This shape in section is best for all dibbers or dibblers, and my smaller ones are fashioned similarly; the usual tool is made circular, and is not so good for penetrating. In making holes for Leeks the main thing to attend to is working the tool sideways, so as to make a wide coned hole, the sides of which are well compressed together; the hole keeps open long and allows better growth, which is checked if the young plant gets nearly buried at the first rain shower. The tops of the plants are nipped off, and by a twisting motion the roots are induced to go down. Care must be taken not to press down when widening the coned hole, or a little soil will have to be dropped in to reduce the depth. When the water is poured in, to complete the planting, it should not be allowed to wash in the sides of the hole. My small dibber was made at the forge from a short piece of gas barrel welded at the tip, coned off, and the end flattened almost chisel-like; the rest of the pipe was slightly flattened to give an oval section; a T piece screwed on the top, and a couple of bits of stick, complete the handle. A good way of using the implement for planting Beans so that "they may see the gardener as he leaves the patch," is to dib holes very obliquely and roll the seed just within the little cave so formed. Birds do not seem to trouble the seeds which are thus practically on the surface. Nearly all my dwarf Beans were thus planted last year, and they will be similarly treated this season. An oval section is preferable for a hoe or serfouette handle: it lies better in the hand than the ordinary round shaft. *H. E. Durham.*

SUGAR BEET.

THE Food Production Department recommends small cultivators to grow Sugar Beet as a source of food for stock, apart from its value as a sweetening agent.

The crop may be sown on a variety of soils, and the most suitable are deep, medium loams. Deep cultivation of the soil is, in all cases, essential. Ordinary farmyard manure may be applied at the rate of from 10-12 tons per acre, with the addition of 1½ cwts. of sulphate of ammonia (½ oz. per sq. yard, 1 lb. per rod), and from 3-4 cwts. of superphosphate per acre (1 1½ oz. per sq. yard, and 2½-2¾ lbs. per rod) before sowing, or the sulphate of ammonia may be halved and one half held over and applied as a top-dressing after singling.

A good tilth is necessary at sowing time, and the seed is usually drilled on the flat, at distances of 16-18 inches between the rows, and 8-10 inches between the plants, or the small grower may adopt the dot system, as recommended in the special leaflet No. 8, issued by the Department.

The rate of sowing is about 10-12 lbs. per acre (1 1½ oz. per rod), and the best time to sow is the last week in April or first week in May. Constant stirring of the soil by the horse or hand hoe, as soon as the rows can be distinguished, tends greatly towards the production of strong, healthy seedlings. The crop is first roughly bunched by the hoe, and then singled by hand. Care should be taken in subsequent hoeings to damage the foliage as little as possible, as the crops yielding the largest sugar content are those which bear the best developed leaf system. The plant requires a long growing season, and should not be harvested prematurely, as the percentage of sugar increases to a marked extent during the final stages of ripening. The lifting period extends from the end of September to the middle of November, or a little later, according to the season. Ripeness is indicated by the leaves becoming yellowish-green in colour and drooping. About three-quarters of the foliage should have wilted, but the central leaves should still be fresh and green. The crop should be lifted and stored before there is any danger of hard frost, and only the tops removed by twisting.

In ordinary conditions a crop of 12 tons per acre may be expected, and there are instances on record where crops up to 18 tons have been obtained with an average of 16.5 per cent. of sugar.

For feeding purposes it is estimated that 4 lbs. of good Sugar Beet are equivalent to 3 lbs. of Mangolds or 1 lb. of cereal meals in mixed rations.

Numerous attempts have been made to utilise the roots for sweetening purposes, and the following recipes for the manufacture of syrup have been found satisfactory by private individuals.

SYRUP FROM SUGAR BEET.

(1) Peel and scrape the Beet and remove every particle of skin, then cut it in slices about one-third of an inch thick. Cover with water for two hours, then simmer for 3 hours, or boil and leave the vessel in a hay-box all night—a hay box is by far the best method. Strain and bottle. The syrup should be of a bright golden colour. In air tight bottles it will keep a month, otherwise only a few days; it is suitable for any kind of sweetening.

After straining the syrup chop the Beet and dry it in a cool oven; it can then be used in place of sultanas for cooking. If the pieces become very hard, soak them for 10 minutes in cold water before using; if they remain fairly soft use them as they are. If the pieces are not required to be used as sultanas afterwards, the raw Beet can be run through a mincing machine before cooking. This method of preparing the Beet for syrup gives a much quicker result.

(2) Clean and boil the Beet until well cooked, then rub the skins off and cut into thin slices and chop them up very fine. Put two pints of water in an enamel saucepan and bring to the boil, then put 2 lbs. of the chopped Beet in, and boil with the lid on for three-quarters of an hour. Press the juice through a fine sieve and strain it through a thick cloth. Put the strained juice into a clean saucepan and bring to the boil, then add half a teaspoonful of bicarbonate of potash. Keep boiling until reduced to one-third, pour into a hot bottle and cork at once. Nett weight of syrup about six ounces.

HARICOT BEANS.

THE French Haricot Bean is a valuable food, very useful for winter, and, when properly harvested, can be safely stored until needed. The white Haricot is a clear, white, plump Bean, plants of which produce a prodigious crop. The dwarf green Haricot is deliciously tender when cooked; the seeds are of a sea-green colour. The former is a Climbing Bean, the latter needs no sticks, and in habit resembles the dwarf Kidney Bean. A peck of seed is sufficient for sowing about an acre. The White Haricot may be sown at a distance of 4 or 5 feet from row to row; if it is desired to plant Brussels Sprouts or Christmas Cabbage between the rows to follow on, then the wider distance is preferable, as, if the crop makes abundant foliage, without plenty of space the second crop is apt to be too much shaded. With the dwarf Haricot the distance may be reduced, as sunshine can reach the pods more directly, and the leafage can easily be reduced at the close of the season if it is at all dense.

Formerly these Beans could be purchased so cheaply that no inducement was offered to at-

tempt their cultivation in England, but at this time the importation of all kinds of pulse is much restricted, and in the future this country must seek to rely more upon its own resources.

The Haricot Bean is susceptible to injury from cold temperatures; care must therefore be taken not to sow too soon, so as to avoid the late spring frosts. The first or second week in May is generally the earliest safe time to sow. A white frost would not hurt the seeds while under the ground; it is when the plants first show above the surface that they are most susceptible to injury from it, as often occurs to the seed potato.

Haricot Beans need rich soil if they are to do their best; but as their life is comparatively brief, they need feeding in such a way that they can readily take up all they require at the moment. This land that was richly manured for the previous crop suits them perfectly, for, being already incorporated in the soil, it is easily accessible.

The soil must be light and friable, and thoroughly well worked. An extra ploughing or some such previous treatment of the surface affords the best chance of success. Beans of this description call for more gentle treatment than many crops; the ground must be friable and without lumps, otherwise the plants will come up "blind."

When the seed germinates, the ground must be kept scrupulously clean, and the hoe will be needed to stir the surface so as to dispose of weeds when small. The plants must be handled very gently, as, unlike many field crops, once knocked down they do not lift up again; thus great care is required to obviate disturbance to the plant. A short handled hoe will be the safest tool to use between the plants so as to secure a clean surface, and, later on, a little mould should be gently drawn to each side of the rows as a support against violent gales. A careful woman, or a boy with a light hand does this work well, but a man accustomed to Turnip hoeing would probably be a failure.

We raised about 23 lbs. of Haricots from 4 poles of garden ground last season, and it appears that with fair treatment and under favourable circumstances good yields could be gained which would prove a useful addition to the food supply of the country.—*W. A. Gibson.*

FREE DISTRIBUTION OF VEGETABLE PLANTS.

Mr. Reginald Cory, Duffryn, near Cardiff, is raising vegetable plants for free distribution among the cottagers of ten neighbouring villages of Duffryn, Llancaitan, Bonvilston, Pendoylan, Peterston-super-Montem, St. Nicholas, Twyn-rodyn, The Downs, Wenvoe and St. George's. The original intention was to supply cottagers with plants of those vegetables which are usually started under glass, but the scheme now embraces every kind of vegetable that can be transplanted.

Printed forms were sent out to all the cottagers, and when these were returned it was found that well over 100,000 plants would be needed.

Delivery will be made in three lots, the first early in May, when Onions, Early Cabbage, possibly Early Lettuce, Red Cabbage, and Early Cauliflower will be sent out. The next delivery towards the end of May will include Tomatos, Brussels Sprouts, and mid-season Cauliflower. Broccoli, Kales and other plants will comprise the third lot.

In addition to supplying vegetable plants Mr. Reginald Cory has given seeds of vegetables other than those included in the plant distribution schemes to the wives of all cottagers who have joined the colours, and has also devoted a hundred guineas to various allotment associations for the encouragement of food production. Miss Cory has given thirty perches of land with complete sets of gardening tools, for the schoolboys of the local St. Nicholas School.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

LYSIOHITUM CAMTSCHATCENSE.—Mr. Watson's remarks on p. 145 (*Gard. Chron.*, April 5, 1913), and the illustration of this plant, seemed so strange to me after having seen the species in Mrs. Knox's garden, that I went to Kew last week to see it. I am now convinced that there are two forms, which, if not specifically distinct, are strikingly different in their habit and colour. On reference to the *Botanical Magazine*, 1904, t. 9,787, I find a figure of the yellow flowered form which was sent to Kew in 1901 from British Columbia, and was growing where it now grows, in a damp, shady corner of the temperate house. Mr. Watson stated that it had previously been unsuccessfully tried in the bog garden in the open air, but this was a plant from North Japan. Nothing was said in the *B. M.* about the colour of the Japanese form, which is white. Now, perhaps, I can explain the reason why the white flowered plant did not thrive at Kew in the bog garden by Mrs. Knox's experience. She received the plant from Japan and grew it most successfully in a pond as an aquatic where it flowers in May, but makes no offsets. The yellow flowered American plant, on the contrary, seeds profusely in the bog garden, a plant lately sent me in flower from Kew having seedlings of last year's growth at the end of the previous year among the flowering growth. The white flowered Japanese plant must be perfectly hardy or it would not live at Flower in Mrs. Knox's garden at 300 feet above the sea, and German states that in Yezo the spathes sometimes appear through the snow. Mrs. Knox tells me that she grows both the forms in water and that the yellow flowered one, though quite as showy and strong as another, both in leaf and flower if in the right water. But in the temperate house at Kew the white variety is alive but weakly, while the yellow flowered one is equally vigorous and twice the size of the same form in the bog garden though the leaves of Mrs. Knox's plant grown in water were much larger, and if I remember right not so erect. I believe I saw the plant in Hokkaido (Island of Yezo) in 1904, but the floods were so high that I could not reach it.—*H. J. Elwes, Colesbourne.*

THE PREPARATION AND COOKING OF DRIED BEANS AND PEAS. These appetising and nourishing foods would be in general use the year round if the modes of preparation and cooking were better understood. Dried pulse (Peas, Beans, etc.) should not be regarded as a separate and casual article of diet, but form the base and substance of at least one meal in each day. It is an important fact that it does take this place in the fare of many foreign and well-nourished peoples. To obtain the full flavour and value of dried Beans and Peas they should be cooked with some fatty material, such as fat bacon or bacon rind, or a piece of dripping or bacon fat, and they should be served with either a white sauce, Onion sauce, Tomato sauce, Parsley sauce, Caper sauce, or cheese sauce. They also form an excellent cold salad with ordinary salad dressing, either separately or mixed with Potatos and any other cold vegetables that may be liked. The method of cooking Haricot Beans is to place the Beans in a basin of cold water for about 12 hours, then gently boil or simmer till tender. The time required for boiling varies from 1½ to 2 hours according to the degree of hardness of the water; if simmered a longer time is required. Fat bacon or other fatty material should be boiled with them, as advised above. Dried Peas should be placed in a basin of boiling water, to which is added two teaspoonfuls of bicarbonate of soda. Cover the basin and leave the Peas to soak for 24 hours, taking care that they remain well covered with water. They should then be taken out, rinsed in clean water, and boiled gently (or simmered) until soft; a pinch of dried Mint and a teaspoonful of sugar should be added to the water, but no soda. The time required for boiling varies according to the degree of hardness of the water; in certain districts three-quarters of an hour may be found sufficient, but where the water is hard one hour may be necessary, or they may simmer for a longer time. When sufficiently cooked strain off the water, butter the Peas, and they are ready for table.—*Burr and Sons.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

MAY 7. *Present:* Mr. E. A. Bowles, M.A. (in the chair), Dr. Rendle, Dr. Bateson, Messrs. Allard, Hales, Fraser, Elwes, and Chittenden (hon. secretary).

Potato Seedlings.—The interesting and comprehensive exhibit of seedling Potatos of the "Castle" strain, shown by Messrs. Sutton, was referred to, and the award of a Certificate of Appreciation to Messrs. Sutton unanimously recommended, on the motion of Dr. Bateson, seconded by Mr. Hales.

Willow Gall.—Mr. Fraser showed young stages of the tassel gall of the Willow, older stages of which have frequently been before the Committee. He found the staminate flowers of Salix alba had been converted into pistillate form by the attack.

Onion Seedlings Destroyed.—Dr. Rendle drew attention to the damaging effect of a proprietary substance sold for killing worms, upon seedling Onions, as a warning against the use of unknown substances for the suppression of pests.

Diurnal Orchids.—Mr. Bowles showed an Odontoglossum with two flowers synanthic, and a Lælia with an abortive labellum.

Narcissus poeticus verus.—He also showed flowers of Linnaeus' form of Narcissus poeticus, a small flowered form, and one of the parents of Crimson Braid.

Various Plants.—Mr. Elwes showed an inflorescence of a Cypripedium, perhaps *C. grande*, Iris Hoogeana, and some of the Regelio-cyclus Irises, a very early flowered Uvaria, perhaps *U. ahoides praecox*; Moraea spathacea, which proved quite hardy in 1917, while the closely allied *M. Huttoni* is always killed in winter; Iris Wattii with inflorescences 6 feet tall, from a cold greenhouse, a close relation of *I. fimbriata*; a Trillium which succeeds remarkably well, seeding everywhere at Colesbourne, and known there as *T. stylosum album*; Fritillaria acmopetala, and the forms known as Elwesii and Whittallii, *F. lutea* and *F. armena*; Muscaria paradoxum and Bellevalia romana.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

APRIL 25.—*Committee present:* Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, J. J. Bolton, D. A. Cowan, J. C. Cowan, J. Cypher, J. Evans, J. Howes, A. Keeling, J. Lupton, D. McLeod, J. McNab, and H. Arthur (secretary).

AWARDS.

FIRST CLASS CERTIFICATES.

Odontoglossum Crawshayanum magnificum (*Harryanum* × *Hallii*), *Odontioda Juliet*, *O. Fire Queen* (*Odn. Bradshawiae* × *Odm. Prinzii rosea*), *O. Bradshawiae Fire King* (*O. Noezliana* × *Odm. crispum*), and *O. Brewii nigrum* (*Odn. Charlesworthii* × *Odm. Harryanum*), from P. SMITH, Esq.

Cattleya Tityus Perfecta (*Enid* × *Octave Doin*), and *Odontoglossum ardentissimum Doris*, from S. GRAFRIX, Esq.

Brasso-Cattleya Lachs Hon. Mrs. Wilson Ashlands var., from R. ASHWORTH, Esq.

AWARDS OF MERIT.

Odontioda St. Teresa (*Odn. Bradshawiae* × *Odm. waltonense*), from R. ASHWORTH, Esq.

Odontoglossum Conqueror (parentage unrecorded), from Messrs. ARMSTRONG AND BROWN.

GROUPS.

Large Silver Medals were awarded to R. ASHWORTH, Esq., Newchurch (gr. Mr. Davenport), and W. R. LEE, Esq., Heywood (gr. Mr. C. Branch), for collections.

CROPS AND STOCK ON THE HOME FARM.

STORE CATTLE.

Now is a good time to get all store cattle from the yards into the open on grass, choosing, if possible, a warm site for a start: shelter from north and east winds is most desirable. It possible, continue to feed with Mangold for a time, as where the grass is old the cattle will not take kindly to it at once. A supply of water is important: some animals require more water than others, but all should have an opportunity of drinking.

CEREAL CROPS.

It is a pleasure to be able to state that, taken as a whole, I have never seen the cereal crops looking so well as at the present time. The dry weather during the whole of March enabled the sowing of Oats and Barley to be done in a satisfactory manner, whilst the rains of April aided germination, giving a fillip to growth which is highly satisfactory.

At one time I feared the Oats might not generally be good in their percentage of germination owing to the very bad weather experienced last harvest, when rain was so continuous that many ricks were made in none too dry a condition, which is apt to produce heating of the whole, thus impairing the germinating power of the grain used as seed. In addition, the Oats were especially light, many samples weighing but 30 odd lbs. per bushel instead of 40 lbs. Yet the growth of Oats this spring is remarkable, and sets one thinking whether we set too much store on highly grown samples of seed corn. Here and there are a few patches of irregular growth, caused by wire-worm attacks, but, fortunately, such instances are rare, except, perhaps, in newly broken up pasture. Much of the defect due to the pest can be traced to the want of stimulative food. Where grass land was ploughed and sown with Oats without receiving manure of any kind, disappointment is in some cases bound to follow, because the grass was in many instances of an unsatisfactory character for the same reason, namely, poverty. I fear many who have ploughed up grass land of this character will be inclined to say "I told you so." In my case I ploughed and sowed Oats on turf that had certainly not been disturbed for one hundred years, but I applied silt, superphosphate, and sulphate of ammonia as advised. I may be told by a common expression "you bought the crop." I am looking farther ahead in my treatment of such crops than the present year. Such a crop will be a good preparation for Potatos, Mangolds, Sugar Beet, Onions, and other root crops.

Wheat promises so far to be the crop of the year. Never in this neighbourhood, which is a fairly large Wheat-growing district, have I seen this cereal so promising. The recent frosty nights and continued cold winds have robbed the plant of some of its colouring matter; this, however, will return with warmer weather. The growth is strong and tillering is vigorous, and where weeding has been carefully done the outlook is most favourable.

THE GROWING OF GRASS AND CEREAL CROPS TOGETHER.

Recently articles have appeared in the daily Press of a startling nature on the dual growth of grass and cereals, which, if found to be of a practical character, will to an extent revolutionise the whole system of production of these crops. We are asked to give the matter a fair trial, which is common sense, but the whole matter appears fraught with objections.

In the first place, I have always regarded the Wheat plant as an annual. I have also yet to learn that the ordinary Tartarian Oat is hardy; the latter does not ripen until the end of August as a rule, and often later, whereas the grass is ready for mowing for hay in June or at the latest in July. In heavy and stony soil I can see difficulties in drilling the corn, and in cutting it if the crop should be heavy and at all laid, but we are told that the grass supports the straw and that the straw crop aids the grass when made into hay. Certainly it may in bulk, but what of its quality? I would certainly go a long way to inspect such a trial before condemning the method. *T. Molyneux.*

MARKETS.

COVENT GARDEN, May 15.

Ferns and Palms: Average Wholesale Prices.

REMARKS.—With the exception of L. longiflorum and Richardias (Arums), the market is better supplied, and prices are lower all round. Double White Narcissus are the leading line in Cut Flowers. There is also a plentiful supply of Narcissus poeticus, which is arriving in good condition. Gardenias, Peach Blossom, Iceland Poppies, Gypsophila, and Stocks are getting more plentiful. There is a shortage of supply. Lilies of the present time, but most of the blooms are damaged by heavy rain, and practically unsaleable. The supply of red Roses is insufficient to meet the demand, but other colours are more plentiful, and a trifle easier in price. Scarlet and white flowers will be in demand during Whitsuntide and Saturday is the Whit-sun Festival.

REMARKS.—Many hothouse fruits are available, including Grapes, Peaches, Strawberries, Melons, and Figs. Among forced vegetables, Peas, Dwarf Beans, Mushrooms, Vegetable Marrows, Cucumbers, Tomatos, and New Potatos are obtainable. Continental Asparagus continues to be obtainable, and English Asparagus is now on offer from all well known sources. Some very fine bundles are arriving from Devonshire. *E. H. R., Covent Garden Market, May 15, 1918.*

DEBATING SOCIETIES.

BRITISH GARDENERS'.—A meeting of the British Gardeners' Association was held in the Assembly Rooms, Bath Street, Leamington Spa, on Saturday, April 20. The chair was taken by Mr. Joe Sides (chairman of the Allotments Federation). An address was given by Mr. Cyril Harding on the aims and objects of the association. He made special reference to the poor rate of pay gardeners received. By organisation he felt sure that the conditions of the gardener could be considerably improved. At the close of the meeting the Leamington branch was reconstituted, Mr. R. Greenfield being appointed secretary.

SCHEDULES RECEIVED.

Liverpool Horticultural Association's Exhibition, to be held in St. George's Hall, Liverpool, on Friday and Saturday, August 23, 24, 1918. Hon. Secretary, Mr. E. R. Pickmere, Town Clerk, Municipal Buildings, Liverpool.

National Dahlia Society's Annual Floral Meeting, to be held in conjunction with the R.H.S. fortnightly meeting on Tuesday, September 10, 1918, in the London Scottish Drill Hall, Buckingham Gate, Westminster. Hon. Secretary, Mr. J. B. Riding, Forest S.fs., Chingford.

ANSWERS TO CORRESPONDENTS.

CORRECTION: *Calceolaria Chibranii* was not raised at the John Innes Institute, as stated by our reporter on p. 200.

CUCUMBER LEAVES DISEASED: *S. G. T.* The Cucumber leaves are affected with the disease known as "spot," caused by the fungus Cercospora Melonis. Do not permit the plants to produce soft foliage, but ventilate the house freely. Remove and burn badly diseased plants, and spray the foliage and soil with liver of sulphur solution (1 oz. to 3 gal. water).

MULBERRY PROPAGATION: *A. D.* The old Mulberry tree you mention may be perpetuated by cuttings. Choose well-ripened shoots of the preceding year, leaving at the base a little of the older wood, and insert them now in fairly rich, but not heavy, soil. They may be planted in rows one foot apart, and 6 inches apart in the rows. Shade them from bright sunshine until they are well established. Another method is to pot the cuttings and plunge the pots in a mild hot-bed until they are rooted, afterwards hardening them and placing them out-of-doors. Water moderately, and protect the plants from severe weather during their first year, after which they may be transferred to their permanent quarters.

NAMES OF FRUITS: *S. A.* Apple D'Arcy Spice. Pippin syn. Spring Ribston!.—*W. B. and S.* Annie Elizabeth.

NAMES OF PLANTS: *Kildare.* Scilla hispanica, the Irish Wood Hyacinth.—*E. D.* Tulip Prince of Austria.—*C. E. I.* 1. Rhodotypos kerrioides; 2. Lathyrus vernus var. carneus flore pleno.

PEAS EATEN: *H. B.* The grubs you send are those of the Crane fly, or "dubbly-do-legs." The best preventives of this pest are good drainage of the land and the removal of useless herbage and weeds; but the best way of getting rid of the grubs now is to encourage the starling, which is inordinately fond of "leather-jackets." If the ground is turned up frequently, insect-eating birds will thoroughly search it for the grubs, and finally completely clear it of these and other ground pests.

ON INCREASED FOOD PRODUCTION.

RUNNER BEANS.

RUNNER BEANS need a rich, holding medium, and grow freely and crop heavily in ground that has been well trenched during the winter and enriched with plenty of animal manure. Failing this treatment, trenches may be made about 2 feet wide and 1 foot deep. The loose soil should be taken out, a fair quantity of farmyard manure placed in the trench, and the dung well forked in with the bottom soil. Replace the top spit of soil on the dung and allow it to settle until the time for planting arrives. It is not advisable to plant Runner Beans in the open too early, especially in the Midlands and North, unless the plants can be protected at night, which is not always practicable. The second or third week in May is soon enough. Poles or long, twiggy Pea sticks should be used to support the plants, and I prefer to place them in position before the Beans are planted, as this plan involves less danger of damaging the roots in pushing the sticks into the ground. Two stout poles should be placed at either end of the row and a wire stretched between in order to fasten the sticks: this is especially necessary if the site is exposed. With good cultivation Runner Beans will grow 10 or 12 feet high and crop from top to bottom of the plants. Before transplanting them from boxes make the soil firm, and rake the surface neatly. Have the boxes handy, and water the soil before removing the plants carefully with a trowel. They should be planted about 1 foot apart and close to the sticks. When the row is completed water the plants by means of a rose can early in the day, that the foliage may be dry again before nightfall. The plants will need tying to the stake at the start, but afterwards they will twine themselves around the supports as they grow. It is not advisable to allow them to make too much growth: they will produce much heavier crops if the shoots are kept thinned, and where time and labour permit this should be done. In dry weather frequent applications of water, both at the roots and overhead, will be very beneficial, and watering is best done in the late afternoons. The pods should be picked as soon as they are ready for use, to allow the younger ones to develop; if not required for use at once, the stalks may be placed in a jar of water in a cool place, when the pods will keep fresh for some time, or they may be salted down for use in winter. A light mulching of half-decayed manure, applied during the hottest part of the season, will assist the plants to grow freely, and greatly lessen the labour of watering. Those who have no facilities for sowing seed in boxes should take the trenches level, as previously advised, and sow the seeds edgeways about 2 inches deep. It is preferable to make the holes with a trowel, and not with a dibber. As soon as the young plants appear through the soil give them a dusting of soot to ward off slugs, and use the Dutch hoe between them on frequent occasions. Subsequent cultivation will be the same as for those planted out. *R. W. Thatcher, Carlton Park Gardens, Market Harborough.*

LATE PEAS.

It is comparatively easy matter to grow a good supply of early and mid-season Peas, but there is generally a difficulty in securing pods during August, September and October. To ensure late crops extra care is necessary in the preparation of the land, and suitable varieties must be selected. I have tried many methods in the preparation of the land for late Peas, and I have for some time come to the conclusion that well prepared trenches are much the most satisfactory system. The trench should be about 18 inches wide and the soil excavated to the depth of about 15 inches. The subsoil should be deeply broken up, and on this should be placed about 10 inches of well-decayed farmyard manure, at the same time applying a dusting of lime or soot. The first of the soil should be returned to the trench and the seeds sown singly, in double rows just as thick again as it is intended the plants should remain, removing every other plant when about 3 inches high, should the rows be gappy from any cause the spare plants may be carefully replanted to make good the failure. One of the common causes of failure with late Peas is attempting to grow the plants too thick. When this is the case they naturally starve each other, mildew is almost certain to appear, and the result is a very short and poor crop.

During spells of drought abundance of water should be given, and liquid manure used freely; the trenches afford a very easy way of applying moisture. Sowings should be made onwards at intervals of ten days to the middle of June.

There are many varieties suitable for late sowing, and some do much better in one district than in another. I rely on those well-tried varieties Autocrat and Masterpiece, the latter undoubtedly being a selection from the former. Both varieties are of fine constitution, give pods of good quality, are much less subject to mildew than many others, and succeed well in most parts of the country. There is still room for improvement in late Peas. We need a larger-podded variety of Ne Plus Ultra flavour (which is unsurpassed as a late Pea in this direction, but not sufficiently prolific). Another desirable quality would be a robust constitution like that of Autocrat. *Edwin Beckett.*

CATCH CROPS UNDER GLASS.

THE members of the Lea Valley Federation of Market Gardeners have this year given a notable example of their desire to do all in their power to promote food production by growing catch crops under glass in Tomato houses. When it is remembered how long the Tomato crop remains on the ground, the time taken up with seed raising and with the preparation of the soil, it will be recognised that it was asking a good deal in these days of shortage of labour for the growers to add to their labours. Furthermore, the suggestion—which came from the Food Production Department—gave but the minimum of time for carrying it out.

Nevertheless, in many cases excellent crops were obtained—particularly of Lettuces White Gott and Black Gott. In spite of the dull weather experienced in early spring these varieties of Cabbage Lettuce—excellent for frame work—hearted well and gave good heads which found a ready market. In some cases, however, the variety sown gave very indifferent results, so poor, indeed, in comparison with the best, as to make it doubtful whether the poor and good plants were of the same variety. The plan adopted was to sow Radish broadcast and to pick out the Lettuces in rows, the idea being to pull the Radish before the Lettuce began to heart. But this year's experience has led to the general opinion that it would be best to sow the Radish in drills. From an inspection of the experiment we think that it may be said to have been successful and to have demonstrated the possibility of squeezing in a catch crop before the main Tomato crop is planted—at all events in those houses the soil of which had not been sterilised. A point in favour of the practice consists in this, that the catch crop does not want fire-heat—the best results were manifestly those in which no more heat had been used than was sufficient to keep out frost. We would congratulate the growers in the Lea Valley on making the experiment, and hope that a further trial on similar lines will be made in the coming year.

ARTIFICIAL MANURES.

As a consequence of the scarcity of farmyard manure many kitchen gardens have not received their necessary complement of animal dung this year. The deficiency may be made good to a certain extent by the use of artificial manures, but it is well to remember that they cannot altogether take the place of farmyard manure. The fertility of the soil is dependent upon texture as well as upon food content, and the continued exclusive use of artificial fertilisers would cause the texture of the land to deteriorate. Furthermore, many artificial manures supply only one of the plants' requirements. Examples of this class are superphosphate of lime, used to supply phosphates, and nitrate of soda, employed to yield a readily available nitrate. Light soils are generally deficient in potash. The ordinary sources of this fertiliser are cut off, but wood ash contains a fair amount of potash: leguminous crops on light land respond well to wood ashes, applied when the seed is sown, at the rate of 3 ozs. per lineal yard of drill. Wood ash should be kept dry to ensure its even distribution, and to preserve the very soluble constituents. On heavy land which has been limed there is usually sufficient available potash to carry the crops without an artificial supply. Superphosphate of lime may be scattered in all drills at the time of seed-sowing. The phosphate gives to the seedling the advantages of a good start. The quantity to use is 2 ozs. per lineal yard. Nitrogenous manures, on the contrary, should not be applied at seed time. They are more useful if used in the season of growth. Those vegetables that grow more than 1 foot in height may have a dressing of nitrate of soda or sulphate of ammonia when they are 6 inches high. There is not much to choose in the two manures, but at present sulphate is the more plentiful. Some growers prefer to dissolve these substances in water before application, but if they are carefully distributed over the soil in showery weather there is no necessity to do so. Use 2 ozs. per lineal yard. In the case of Potatos, apply the sulphate of ammonia immediately before the first and second earthing. Cabbages, particularly at the present time, will also respond to a dressing of sulphate of ammonia. The quantity required is 3 ozs. to the square yard. Onions respond particularly well to dressings of soot. They may be given fortnightly from the middle of May onwards. Should showers not be opportune the application may be made in the evening and be thoroughly watered in. It is probable that the odour of soot acts as a deterrent to the Onion fly. Dressings of soot are also beneficial to Carrots and Parsnips, and may be applied in the same way as suggested for Onions. *Geo. H. Copley.*

LETTERS FROM SOLDIER-GARDENERS.

WHAT WE MAY LEARN FROM THE ARMY RIVETTING.

In a military sense, the term rivetting means using various kinds of material to hold up loose soil in a more or less vertical position. The means adopted seem to me to possess some horticultural uses and possibilities.

The materials generally employed for rivetting are sheets of corrugated iron and wire netting of various types. Wattle hurdles are also used at times, and are found very effective. The wire netting is stretched along the sides of the trench and stout posts are driven in to keep it in place. The most common of all methods of rivetting is by building sandbags up the sides. Good work of this description should present one row of headers and one of stretchers. In other words, one row has the bags placed lengthways and the succeeding row has the bags of earth with their ends forming the facing. We are unlikely to find any need for using sandbags of earth in gardening, although it may be said that a well-built wall of sandbags always reminds me of a dry-wall used in gardens for growing suitable plants in the crevices. It is customary in many gardens, and I hope it will soon be general, to make a large, long, rectangular heap of leaves in autumn and winter and provide bottom heat for box frames, to be used for forcing and forwarding vegetables. Without straw or litter it is practically impossible to build these heaps so as to bear the necessary traffic of attending to the frames, and they might be enclosed by thick, strong, coarse meshed wire netting, kept in place by stout posts. Wattle hurdles or sheets of corrugated iron might also be employed for the purpose. Not only would the leaves be kept in position despite the treading, but they would not be blown about and cause a nuisance in other parts of the garden. Where the height of the enclosure approached 4 feet Tomatos could be grown in summer against that portion exposed to sunshine.

There is another case where I think this method of rivetting might be used horticulturally. Soil could be banked in the shape of a dry wall, faced with any stones which happen to be at hand, and rivetted with coarse-meshed netting kept in place by poles. The posts could soon be furnished with suitable plants, and when the face of the wall was draped with Aubrietia, Arabis, and the many other suitable subjects, I could, few would be so hypercritical as to complain of the appearance of the wire netting.

There is another kind of rivetting to which I would like to call attention. Even miles behind the firing line the huts and tents are protected from shell fire and bombs. Obviously, it is impossible to protect oneself from a direct hit, but there are more casualties from splinters than from direct hits, and it is possible to protect the occupants from the majority of these. I am giving away no military secret in showing how this is done. About 2 feet from the outside of the hut, and all round it, is built up an enclosure of wire netting, which is about 4 feet high, 3 feet wide at the base, and 2 feet at the top. This enclosure is held in place by posts driven in at an angle, so that each pair inclines to the other. The space is then filled with soil.

I have often thought how pretty these places could be made to look if we could clothe them with Arabis, Aubrietia, Cerastium, Saxifraga, Sedum, Sempervivum, Alyssum saxatile or argentium, Nepeta Mussinii, Iberis sempervirens, Wallflowers, Erysimum, Viola cornuta, Valerian, Dianthus, Helianthemum, and similar plants. Even such subjects as Ivy leaved and Zonal Pelargoniums would conceivably do well if the soil was suitable.

It would also be possible under a rivetting scheme similar to that suggested to build a wall of soil, say, 1 foot thick, with perpendicular faces, to be used as a pit. We need then only set over it a framework to guide the lights, to obtain as inexpensive cold pit. In the case of a hole dug to receive fermenting material for forming a hotbed, the various methods of rivetting the sides to which I have already alluded would prove very useful. *William F. Rowles, B.E.F.*

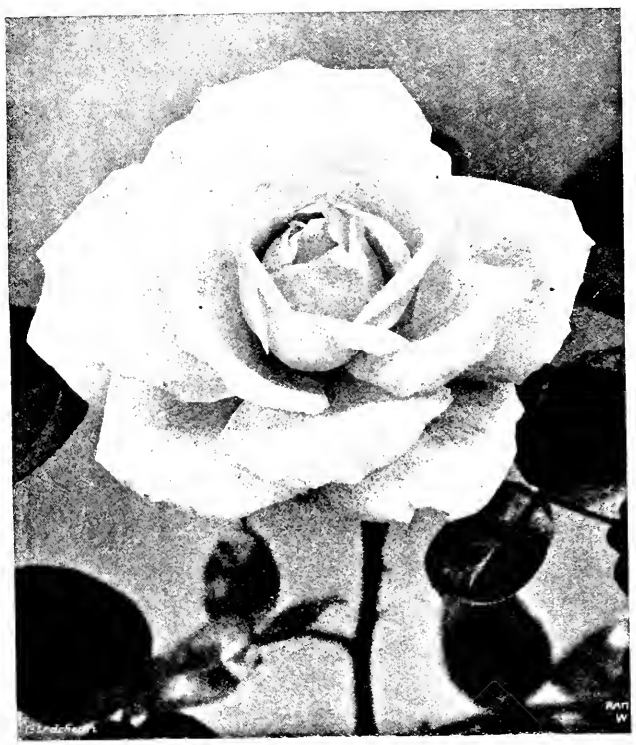

FIG. 92.—ROSE MRS. ELISHA HICKS: PETALS BLUSH WHITE, THE CENTRE ONES PALE PINK.

THE ROSARY.

FRAGRANCE IN ROSES.

Fragrance in the Rose is among its greatest charms, and it would be well if it could be considered an essential attribute in a first-class flower. Unfortunately, judges of exhibition Roses have never been directed to pay any attention to their fragrance, with the result that among the Roses most frequently exhibited in boxes there are several which are defective in this respect. Instances that occur to one are Frau Karl Druschki, Mildred Grant, Lyon Rose, Mrs. Theodore Roosevelt, and perhaps Mrs. J. H. Welsh, all of which are high in the exhibition list. Perhaps it is because these Roses and others like them are so often seen at shows that it has of late become customary to deplore the fact that the modern Rose is lacking in perfume.

I am by no means willing to admit the truth of the indictment, and feel confident that those who bring the charge do so only because they have not been at the trouble to seek for the charm of fragrance in the modern Rose.

True it is that many of the old-time Roses were sweetly perfumed, such as Marie Baumann, Etienne Levet, Horace Vernet, Sénateur Vaisse and Général Jacqueminot! Is it not a joy to put one's nose into any of them and inhale their refreshing odour? But an equal pleasure can be obtained from many new varieties, if we are only careful in our choice. Mrs. George Norwood, Queen of Fragrance, Colcestria and Hoosier Beauty have all the charm of the rich Rose perfume that many attribute to the Damask Rose.

There are some who profess to find the scent of various kinds of fruit in the derivatives of Persian Yellow, which we owe to the industry of M. Pernet Ducher. I am not one of these. Not that I doubt their statement for a moment, but I have arrived at the conclusion that my sense of smell is defective in this respect and does not respond to these fruity odours; thus Rayon d'Or and Louise Catherine Breslau are to me odourless.

Be that as it may, I none the less welcome warmly the arrival of a flower with the full Rose perfume, and all the more when it is particularly good in form. Both these attributes are to be found in the variety Mrs. Elisha Hicks (see fig. 92), which was exhibited at the Drill Hall on the 7th inst., when the National Rose Society arranged special classes for Roses.

The bloom of this new variety is of medium size, but perhaps large enough for the front row of the exhibition box, and has a pleasing, pointed form, with sufficient petals to be described as a full flower, and, as shown, appeared to carry itself well on a good stiff stem. The colour is blush-white with pinkish flesh shade in the centre of the flower. The colour, no doubt, is the weak point of the Rose, for though the blooms that were exhibited looked delightfully fresh, yet one knows that flowers of this tint sometimes seem rather wanting in character in the garden. The fragrance, however, was full, strong, and most captivating, so as to give quite a distinctive character to the variety. I hope we may find flowers from plants grown in the open equally good. *White Rose.*

NOTES ON CONIFERS.

XIX.—ABIES FRASERI.*

WHILE inspecting the young trees in what is known as the Centenary Plantation on Mr. Elwes' estate at Colesbourne last August, I was much interested to find two vigorous young specimens of this rare Balsam Fir, which, strange to say, although planted in a situation peculiarly subject to late and early frosts, at about 500 feet above sea-level, have succeeded as well as any of the Conifers planted there for experimental purposes, and have remained in a healthier condition than any other Fir that has been tried in a locality where hardly a single species has escaped injury from frost. In the published notes on this plantation† these two trees are mentioned as having come from Barbier, Orleans, as Abies Fraseri. Mr. Elwes says they were planted about fourteen years ago, and he considers their identity doubtful, but I have no doubt in my own mind that they are correctly named. At present these trees look like making really good specimens, as they are now about 15 feet high and making vigorous growth. They were planted in a clayey loam, known geologically as "Midford sand" which is of quite a different nature from the surrounding oolite. Last year they produced an abundance of cones, as will be seen from the branch illustrated in fig. 93, and the cones, with their reflexed bracts, at once give an additional clue to their identity. However, it is quite possible to dispense with the cones for the purposes of identification, as A. Fraseri may always be known from its near ally A. balsamea, by its branchlets being more densely pubescent and the broader lines of stomata on the lower surface of the leaves, which are coriaceous in texture. The leaves are also shorter and broader than in A. balsamea.

There is no record of Abies Fraseri having attained any considerable size in this country. All the specimens I have seen hitherto have been a few feet high, generally in nurseries where it is sometimes confused with A. balsamea. The latter seems to be much commoner in cultivation. The cone-bearing branch of A. Fraseri figured in Mr. Clinton Baker's *Illustrations of Conifers* was from a dried specimen in the Kew Museum taken from a tree which used to grow near Moreton-in-the-Marsh, Gloucestershire. This species also formerly existed at Bayfordbury but the tree planted there in 1838 was killed by the terribly severe winter of 1860, which was responsible for the death of many rare and interesting Conifers all over the country.

Abies Fraseri was named after its discoverer, John Fraser (1750-1811), a keen collector of North American plants. He found it in the Alleghany Mountains about 1800. In its native country it has a very local distribution, being found wild only on the Alleghany Mountains in South-Western Virginia, North Carolina, and Eastern Tennessee, where it forms forests at 4,000 feet to 6,000 feet elevation. Its usual height is about 40 feet, but trees up to 70 feet high are on record. Abies Fraseri was first cultivated in this country in 1811, when plants were distributed from Charles Lee's nursery at Hammersmith. The figure in the *Pinetum Woburnense*‡ was taken from the original tree in this nursery, where it had attained a height of 16 feet, and was then about 28 years old. It is very unlikely that any of the original specimens are now living, as this Fir, like A. balsamea, is a short-lived tree. *A. Bruce Jackson.*

‡ It had not been known at Woburn since Forbes' time until young plants were recently introduced.

OLD FRENCH GARDENING BOOKS.

MR. BENYARD'S discovery as to the authorship of *Cotton's Planter's Manual* supports what I have so often emphasised—that our earliest garden literature was in the main nothing more or less than translations from the French.

If we begin with Peter Treveris's *The Grete Herball*, one edition of which is reported to bear upon its title-page "translated out ye Frensshe into Englysshe," we shall find many other English works to follow that owed their origin to French writers. The original of *The Grete Herball*, was no doubt *Le Grant Herbier en françoys Contenant les qualitez Vertus & proprietez des Herbes, Arbres, Gommes, & Semences*, which it is believed was first published about 1520, a strong argument in favour of the contention that the so-called *Grete Herball* of 1516 is due to a mere transposition of figures.

[Photograph by E. J. Wallis.

FIG. 93.—BRANCH OF ABIES FRASERI WITH CONES (REDUCED) FROM COLESBOURNE.

A printer's error, in fact, since nobody has ever seen a copy of it since Ames mentioned it in his *Typographical Antiquities*. Mrs. Arber* points out that *Le Grant Herbier* itself was not an original work, but as regards its text and illustrations was derived from earlier sources.

I may refer to another of these old Herbals which I have not been able to trace, that is, a Flemish one called *Groote Herbarius*, printed by Claes de Grieve, 4to, Antwerp, 1514. Probably this, too, owed its origin to the same source as the English and French editions.

Leonard Mascall's *A Booke of the arte and maner, how to plant and graffe all sortes of trees, etc.*, the first edition being printed in London in 1572, is none other than *L'art et maniere de semer pepins et de faire pepinieres*, by David Brossard, a Benedictine monk whose book appeared twenty years before Mascall's translation. Of "Short Instructions, very profitable and necessary for all those who delight in gardening, translated out of the French into English," printed by John Wolfe, 1592, I have failed to discover the original author.

Surflet's *Maison Rustique; or, the Country Farm*, published in 1600, is, of course, Estienne's famous work bearing the title, which served for so many editions of the *Maison Rustique*. In 1616 Gervase Markham, the author of *A Way to get Wealth*, issued an English edition under the French title.

The famous John Evelyn, in 1658, issued *The French Gardiner*, a translation of *Le Jardinier François*, by Nicholas de Bonnefons, the first edition of which appeared in 1651 and the last in 1761, an important book in France, seeing that it was issued during a period which lasted for 110 years.

Evelyn, also in 1693, produced *The Compleat Gard'ner*, a translation of the famous Jean de la Quintinye's *Instructions pour les Jardins fruitiers et potagers*, 2 vols., 4to, published in 1690, two years after the death of the great Frenchman.

John Foster, in 1664, published *Le Gendre, The manner of ordering Fruit Trees*. The original of this work was by Le Gendre, Curé d'Heuonville, and was entitled *La manière de cultiver les arbres fruitiers*, being published in 1652. It was the first of a long series of high-class works by French authors on fruit culture.

Another English book, *The Art of Pruning Fruit Trees, . . .* Translated from the French original, set forth the last year by a Physician of Rochelle," dated 1685, is easily identified with *L'art de tailler les arbres fruitiers* par Nicholas Venette, médecin de la Rochelle. One edition of it appeared in 1678, another in 1683.

In 1699 London and Wise issued *The Compleat Gard'ner . . .* by J. de la Quintinye, now compendiously abridg'd."

* *Herbals: Their Origin, &c.* Camb., 1912.

The same firm also published *The retir'd Gard'ner*, in 1706, in two volumes. One of these was Louis Liger's *Le Jardinier Fleuriste*, published in 1703, and the other Gentil's *Le Jardinier Solitaire*, a work exclusively devoted to fruit culture which ran through many editions for the best part of the eighteenth century.

Simultaneously with the appearance of London and Wise's translation of these two French works, another came out bearing a lengthy title, the material part of which is *Le Jardinier Solitaire, The Solitary or Carthusian Gard'ner, being dialogues between a Gentleman and a Gard'ner*. These two French gardening books must evidently have been thought a great deal of by English horticulturists, for we find that in 1717 Joseph Carpenter published a revised edition.

Under the title of *The Theory and Practice of Gardening*, John James, in 1712, published *Dezallier d'Argenville's La Theorie et la pratique du Jardinage*, a quarto, illustrated by Le Blond, first issued in 1709, and which Bloomfield, in his *Formal Garden in England*, describes as a masterly treatise on the subject.

William Fleetwood, in 1707, brought out *Curiosities of Nature and Art in Husbandry and Gardening*. The original of this work was written by the Abbé Vallemont and published in Paris in 1750 under the title of *Curiositez de la nature et de l'art sur la végétation*.

A work by Samuel Humphreys, called *Spectacle de la Nature: or Nature Display'd*, a new edition, 1736, contains in Vol. II. a large amount of information in dialogue about flowers, gardens, cultivation and pruning of fruit trees, husbandry, and vines. The Abbé Pluche was the author of this popular encyclopaedia, which bore the French title, *Spectacle de la Nature*.

De Combes—or De Combles, for I find the name spelt both ways—wrote a *Traité de la culture des Pêchers* in 1745. Several editions, extending over half a century, appeared. There is a rare translation of it into English extant entitled *A Treatise upon the Culture of Peach Trees*, printed and sold by J. Dodsley in 1760.

From this time onward English translations from French authors become fewer, and no doubt our own gardeners were, as time went on, less dependent on the experience of our French neighbours. *C. Harman Payne.*

AUSTRALIA.

LILIES IN A SYDNEY GARDEN

I AM forwarding you by this mail two photographs [Not reproduced.—EDS.] of a plant of Lilium sulphureum grown by me at Wahroonga, near Sydney.

The inflorescence produced 16 flower-buds, and at the time the photograph was taken 13 flowers were open, but the next day two others opened, and 15 were in bloom at the same time. The stem was 9 feet 4 inches high and 5½ inches around the base.

Unfortunately I did not measure the length of the flower-buds, but, with the exception of the top bud, which would only be between 6 and 7 inches, they were anything from 8½ to 10 inches.

I have frequently had plants over 8 feet high, and one, with 9 flowers, was 8 feet 7 inches this year. Some were very slightly thicker around the base of stem than the one mentioned above, but nothing like the 5 inches mentioned by Mr. F. W. Sivers in *The Journal of R.H.S.*, Vol. XXVI. (1901), Parts 2 and 3. Perhaps the height accounts for this.

My experience is that after the flowers have been open for a couple of days, a very hot, scorching sun will slightly burn the back of the edges of the blooms, but not sufficient to spoil their beauty.

The soil of the bed in which my plants were grown is composed of leaf-mould, sand, burnt earth and rubbish, dried roots, and loam, but I think our climate (we are 620 feet above sea-level) has the most to do with success, and is particularly suitable to this Lilium, as bulbils, only two years old, grow over 5 feet high, and many have produced a single flower this year.

Established bulbs of L. sulphureum may be depended on to show above the ground each year without varying one week in time. They are always in sight from October 24 to 31, and in full bloom by the third week in January.

I had very fine success with L. speciosum roseum this year; one bed contains 36 plants, some of which were 7 feet high, with up to 21 flowers on a stem. This Lilium does well here if not disturbed.

My bulbs of L. speciosum rubrum, L. s. album Kraetzeri, and L. s. Melpomene do not do very well, but I attribute this to never yet having been able to get good bulbs—in fact, I have not had much success with any of the Japanese bulbs. The best I have done with L. auratum is to grow a plant 7 feet high with 13 flowers. *A. P. Sparke, Sydney.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey

SWEDE TURNIPS.—The garden Swede is a valuable addition to other vegetables for winter and spring use. Sow a few rows on rich ground which has been liberally manured with farmyard dung. Use the hoe freely between the drills during the summer to encourage the Turnips to make free growth and to keep the ground clear of weeds.

ONIONS.—Thin maincrop Onions as soon as the plants are advanced sufficiently, and take the opportunity to remove all weeds that are present. Do not thin the plants severely unless extra large bulbs are required. Where the Onion maggot is troublesome, the thinning should be done when the plants are small, but do not remove too many, as some may fail. Encourage the plants to make good growth by stirring the soil lightly and dusting the plants frequently with old soot in dull, damp weather. Where the seeds have germinated unevenly or in patches, the blank spaces may be filled by transplanting some of the plants when they are about 6 inches high; choose showery weather for this work. If the transplanting is done quickly and well the plants will soon catch up to those that have not been disturbed.

MARROWS.—Amateurs especially should grow Vegetable Marrows, not only because they are easily cultivated, but also because home-grown Marrows are far superior to those sold in shops. In favoured localities the plants often succeed better in the open than on special heaps of manure in out of the-way corners. A mild hotbed is an advantage for early supplies, and a sunny position should be selected. When the Marrows are grown on heaps of manure or decaying rubbish, the heap should be made in a sunny, sheltered position. If young plants are in readiness, they should be hardened off and planted out early in June, or seed may be sown where the plants are to grow; they will germinate in a few days. Long Green and Long White are the most favoured large varieties; Sutton's Vegetable Marrow and Pen-y-Byd give Marrows of medium size and are prolific croppers. The more closely the Marrows are cut, the more productive the plants will be.

THINNING AND TRANSPLANTING.—Although many early sown seeds have not germinated well, there is much thinning to do amongst seedlings, and a considerable amount of transplanting is needed. This latter operation is best done in showery weather, for when the soil is moist the plants are more easily drawn out, and those that remain quickly re-establish themselves after the disturbance. The advantage of early thinning cannot be over-estimated. Turnips need first attention; they transplant readily, but at this early season transplanting scarcely repays for the trouble. Early Carrots may be thinned and the small roots made use of, leaving the remainder 4 inches apart. Moderate sized roots are the most useful. Parsnips should be thinned to 6 to 9 inches apart. Beet is not far advanced; large roots are not the best, and too much room should not be allowed. A suitable distance apart is 6 inches. Thin Salsify and Scorzonera to 6 or 8 inches asunder.

MULCHING.—Mulching is one of the most important operations at this season of the year, and especially on light soils. Immediate mulching is not absolutely necessary, especially in the case of cold, heavy soils, and may be deferred until the sun's heat has well warmed the ground. As the roots are not in a condition to receive stimulants, rich manure should not be used, yet a covering of some kind that will prevent evaporation and absorb sun-heat is needed. Peas, Beans and Cauliflowers are all improved by the timely application of mulches, and those who succeed best always err on the side of moderation, both in strength and quantity of the mulching. Clean the ground thoroughly before applying the manure, and water the roots freely in dry weather, using stimulants where necessary, according to the requirements of the crop.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to Mrs. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

EARLY VINERY.—The Grapes in the early vinery will not finish well without plenty of fresh air, but cold draughts must be prevented. Fire-heat will still be necessary to prevent the temperature from falling too low, but a close atmosphere will ruin the bloom. Leave the top and bottom ventilators open a little at night to prevent condensation of moisture on the berries. In a few weeks the Grapes will begin to ripen, and then the house should be kept cooler and drier; but the floors, bare spaces and borders should be damped in the forenoon during bright weather. Every precaution should be taken to keep the foliage free from red spider; if the pest makes an appearance, sponge the foliage with warm soapy water containing a little sulphur. Or if the syringe can be employed without wetting the Grapes, spray the foliage daily with tepid rain-water until the pest is eradicated. Vines occasionally become dry at the roots, especially in a corner or under the water-pipes, and in such cases red spider is sure to be troublesome. A good mulching of short stable manure, well watered, is the best preventive. The vines will absorb the moisture before evening if the mulch is applied in the early part of the day.

PEACHES AND NECTARINES.—The fruits on the Peach and Nectarine trees in the early houses are swelling and colouring fast; a few of the earliest varieties are even ripening. Place nets under the trellis to catch any fruits that may drop. Very few will fall, however, if the trees are examined every morning, and the ripest fruit removed with a pair of vine scissors. The flavour is much improved if the fruits are gathered just before they are quite ripe and placed in a warm fruit-room to mature. Plenty of fresh air is of the greatest importance to all fruits approaching maturity. In the case of Peaches and Nectarines, the ventilators should be left open a little at night, as the warmth in the pipes will maintain a night temperature of 60° at this period. Syringe the trees with soft water (hard water usually contains lime sediment, which disfigures the fruit), but water must be withheld when the fruit is ripening. Admit sun and air by carefully regulating the shoots, pinching those that will be cut out when the fruit is gathered.

EARLY STRAWBERRIES.—The earliest plants that have occupied the shelves in vineries and Peach houses should be discarded directly the fruit is gathered. To retain these hard-forced plants would serve no useful purpose. Successional batches may be reserved for autumn fruiting, and the best of the latest plants selected for planting outside. Dip all the plants

in an insecticide or a solution of soap and sulphur before they are placed in frames to harden; in a few days they will be ready to be placed outside. Give the shelves in the houses a thorough cleansing with strong soapy water, taking extra care if red spider is troublesome.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to SIR JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

STANHOPEA.—Plants of Stanhopea tigrina, S. Wardii, S. Amesiana and others that require fresh rooting material should be attended to after they have passed their flowering period. Shallow Teakwood baskets form the most suitable receptacles, as their pendulous inflorescences push downwards. A layer of Fern rhizomes should be placed over the bottom of the basket for drainage, in preference to crocks. These plants resent frequent root disturbance; any requiring increased rooting space should therefore be placed in pots large enough to accommodate them for at least two seasons. In cases where the plants have sufficient root room, and the compost is in good condition, portions of the soil should be picked from the surface, and a top dressing of fresh materials applied. The plants grow best suspended from the roof in a moist, shady position in the intermediate house. They should be watered sparingly during their earliest stages of growth, but after the new pseudo bulbs begin to form they will require liberal supplies of moisture at the roots, and frequent overhead sprayings.

ACINETA.—Plants of Acineta Humboldtii, A. Barkeri and A. chrysantha are developing inflorescences, and care should be taken that the soil is not overwatered, or the flower-buds may drop. Attention should be paid to the roots after the plants have passed out of flower and new growth has commenced to develop. At that stage they should be given similar treatment to that advised for Stanhopeas.

VANDA KIMBALLIANA.—If plants of Vanda Kimballiana require attention at the roots the work should be done now, but they should not be disturbed unless it is absolutely necessary. These plants grow best in Teakwood baskets, with clean crocks for drainage purposes, and clean-picked Sphagnum moss as a rooting medium. Plants that have lost a quantity of their bottom leaves should be taken out of their receptacles to allow portions of the stems to be cut away below some of the aerial roots, so that they may be placed lower down in the baskets. Plants treated in this manner should be grown in a shady position and syringed frequently for a few weeks afterwards. This Vanda grows best when suspended from the roof rafters. During the season of active growth the night temperature should range from 60° to 65°, with a rise of 5° or 10° during the day.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

LILIUM.—Lilium speciosum may now be placed out of doors in a sheltered position. Plunge the pots up to their rims in ashes to prevent the plants from being damaged by rough winds. This will also prevent the roots from drying quickly. The growths must be supported with neat stakes. If there is room in the pots a top-dressing of some rich material should be afforded. Spray the plants occasionally with an insecticide to prevent attacks by green or black fly. Lilium candidum has done well here this season, and has responded well to forcing. This fact is worthy of note, as it is safe to say that there will be no importation of Liliums of any kind for some time to come.

CINERARIA.—A sowing of this useful plant should be made now. The stellata type is probably the most decorative of all the Cinerarias, and as there are both tall and dwarf forms of this type, a good batch of it should be grown. Sow the seeds in shallow pans filled with a finely sifted compost of loam, leaf soil and sand. Carefully water them with a fine rose can, and place them in a cool house to germinate. Place a sheet of glass over the pans, and keep them shaded till the seedlings are through the soil. Cinerarias should be grown in cool conditions during all stages of growth. Another sowing may be made next month to obtain plants for later flowering.

HIPPEASTRUM (AMARYLLIS).—Hippeastrum plants which have flowered should receive every attention to enable them to perfect their growth. Use a stimulant at every alternate watering, and never allow the roots to suffer for want of water until growth is completed. Water should then be gradually withheld and the plants exposed fully to the sunshine.

FUCHSIA.—Young Fuchsias which were rooted last autumn or early this year may be stopped if they are intended for bushy specimens, but those required to grow under the roof of the greenhouse should be kept growing freely in a moist, warm atmosphere, and all side shoots removed until they have grown tall enough for the purpose. They may then be allowed to develop side shoots. The same remarks apply to those intended for training as standards. Old, established plants need liberal treatment in watering and feeding when in active growth, or their flowering season will be short. Fuchsias need very little shade except when they are in full flower.

HYDRANGEA HORTENSIS. If the blue variety of the common Hydrangea is watered with the preparation "Azure," it will intensify the colour. The ordinary varieties are developing their flowers, and must be given plenty of stimulants. See that each flowering shoot is securely fastened to a stake, or the flowers will be damaged when moving the plants.

ASPIDISTRA. The principal object to aim at in the cultivation of Aspidistras is to secure good variegation in the leaves. Growing the plants too much in the shade and over potting them will defeat this object. The plant will thrive for many years without repotting, provided the drainage is kept free, the roots well watered, and given plenty of nourishment. If repotting is necessary, use a rich compost, and pot very firmly. Afterwards grow the plants in a light house, shading them only during the hottest part of the day.

THE HARDY FRUIT GARDEN

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

AUTUMN RASPBERRIES. The young shoots, if too numerous, should be thinned to the required number for training. If stray suckers appear pushing up out of place cut them off. Should any immediate increase of the stock be needed the superfluous young suckers may be transplanted. I have done this in the spring with the Hailsham berry quite successfully, and fruited the plants the following autumn. This is one of the most prolific varieties with us on our shallow soil.

PROTECTION.—There is in some districts a scarcity of netting for protecting fruit, and therefore supplies should be secured in good time. Square meshed netting is far superior to the old diamond shaped mesh. Not only does it hang better, but it goes much farther. If it is intended to rest on the fruit, the light make is best, though it is not quite so durable. It is a good plan to fix stakes over all bush fruits and Raspberries. The stakes should be made out of quartering, 3 inches by 4 inches, or 3 inches by 3 inches, at least 6 feet 6 inches long, and, when pointed, should be tarred for 18 inches from the base. There is no better plan for covering Strawberries than by this method. A stake at every 12 feet or so, with stout yarn strained over the top each way, will easily support the netting.

GATHERING AND PACKING FRUIT.—Dessert fruit should be picked into square punnets and sent straight to the table without further handling. Packing for transit must be more carefully done. Boxes into which the square punnets will fit, without room for movement, are to be had from makers who specialise in such things.

NEWLY GRAFTED TREES.—Grafts inserted this spring should be examined; if the clay is cracking, moisten it occasionally, or lay a little moss upon it. Look to the young shoots where they are on the move, and see that no insect attacks them and deforms the young growth. Do not let the stock increase its growth so much as to rob the scion.

CHERRIES.—Cherries in favourable positions have already set freely. Do not let the trees suffer for want of water; this may not happen yet in the open, but close to walls there is danger of drought. Cherries should never be permitted to become dry at the roots, especially when the fruit is swelling.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

THE ROCKERY.—Iris stylosa, which usually is shy to bloom, has done well this season, and Primula Juliae, one of the showiest of rockery plants, has been as gay as in former years. Much work needs attention, such as cleaning off the decayed flowers of the earlier plants and destroying weeds which are making their unwelcome appearance, especially where fresh soil was introduced early in the year. Weeds should never be allowed to gain a firm footing in the rock garden.

ANNUALS.—Early-sown hardy annuals are ready for thinning. On light soil it will prove beneficial, after destroying the superfluous seedlings, to tread the ground around those left. The great majority of annuals transplant readily, and use may be made of these to fill any gaps that have been overlooked or where there have been failures of seeds to germinate.

AFRICAN MARIGOLD.—The African Marigold is of great value for transplanting in autumn when in flower to fill parts of borders which were occupied by earlier flowering plants. This practice has another advantage, inasmuch as doubles may be kept apart from singles. Not that the latter are less to be commended than doubles, but the two types are best kept apart from a decorative point of view. They all require a space of about 18 inches to permit of their full development.

CHRYSANTHEMUMS.—Surplus stocks of early Chrysanthemums may be treated similarly to Marigolds, and for the same purpose—filling gaps in autumn. They require rather more space, and should be very firmly planted, and treated with superphosphate, soot or pigeon manure, to produce a strong, hard growth.

TUBEROUS-ROOTED BEGONIAS.—The frames and houses containing tuberous rooted Begonias for the flower beds should be ventilated very freely, but the plants must be protected at night. They should always be watered in the mornings, but never profusely. So long as they do not suffer from lack of moisture at the roots, plants that are treated as above turn out much better, take hold of the soil sooner, and do not need much attention in the way of supplying them with water after being planted. Do not hurry to plant these tender flowers where late morning frosts prevail.

FLOWER BEDS.—The chief beds and borders for bedding plants that were dug or trenched in late autumn should be prepared by forking the soil and breaking any clods that still remain. Afterwards whiten the surface with a dressing of superphosphate of lime, then make the soil firm by foot trampling, and finish by stirring the surface, when it will be ready for planting. It may be remarked that superphosphate, in addition to its value as a manure, has a great and additional value in brightening the colours alike of flower and leaf.

MIXED BORDERS.—Many plants usually provided for summer flower-beds are useful to fill blanks in mixed borders. Thus Verbena venosa may be mixed with white flowered Lychnis; Agrostemma is beautiful; Lobelia, either dwarf or tall, is equally suitable; Gazania splendens, Ageratum mexicanum, tall Snapdragons, Tagetes signata, T. lucida, varieties of French Marigolds, and Verbenas of sorts are others that occur to one's mind at the moment. All these plants may be massed in groups or interspersed among permanent plants with which it is known they will associate perfectly.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save as much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR JUNE.

SATURDAY, JUNE 8:—
Kew Guild ann. meet., Kew Gardens, 6 p.m.
TUESDAY, JUNE 18:—
Royal Hort. Soc. Coms. meet

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 56.2.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, May 23, 10 a.m. Bar. 30.0; temp. 65.5°. Weather—Rain

American Gooseberry Mildew.

After one or two years' comparative quiescence American Gooseberry mildew has made its appearance in a severe form in some parts of the country, and, indeed, some half-formed berries from one district appeared more like Snowberries than Gooseberries, so covered were they with the summer stage of the fungus. It is to be feared, therefore, that unless the present happy turn in the weather effects a change for the better, we may be about to experience another bad year so far as this disease is concerned. This is the more to be deplored in that the Gooseberry is a fruit specially valuable to the jam makers, presumably because of its richness in the pectins which give a set to jam. It is therefore to be hoped that everybody who grows Gooseberries will recognise the duty of spraying the bushes immediately. Mr. Salmon and his colleagues at Wye College have shown that, for most varieties at all events, lime sulphur is an effective wash, and Dr. Horne's trials at Wisley indicate that the disease may be controlled by a Burgundy wash—although, as is the case with lime sulphur, certain of the more delicate varieties of Gooseberry are apt to be defoliated as a result of spraying. The point, however, which should be borne in mind by all growers is that the more generally is spraying practised the better is the chance of checking the spread of the disease. Scarcely less important is the fact that the spores may be carried long distances on the clothes of persons walking among diseased plantations, and thus carried may—all unconsciously on the part of the carrier—infect distant plantations. The waxing and waning of this disease in different years is as interesting as it is puzzling. It looks as though climatic conditions had the casting vote in determining whether or no the disease should declare itself. But if this is the case, it will probably be found that the quickest way to rid the country of the pest will prove to be by spraying in the mild years no less than in the virulent years. For it is likely that in the mild years small unobserved outbreaks occur, and that the crop of spores produced by these unnoticed outbreaks suffices to sow enough "tares" in the form of resting spores to produce serious effects so soon as a mild year is followed by one in which the climatic and seasonal conditions make for virulence; that is, favour the growth of the fungus as compared with the plant. Systematic exploration of Gooseberry plantations in years noteworthy for the lack of disease might provide the clue to the problem of the manner in which the disease remains endemic in spite of years unfavourable to its development. It may be, of course, that the "resting" spore cases (perithecia) may lie dormant in the soil for more than a year—that, as in the case of certain seeds, some "germinate" after a relatively short interval of time, and some only after a longer period. But observation alone can settle this point, and it is one of such importance that settled it should be.

FLOWER FAIR IN TRAFALGAR SQUARE.—The National Rose Society and several nursery firms have given their support to a flower fair which will be held in Trafalgar Square during the week June 20-26, with the object of securing funds for the maintenance of the "British Ambulance Committee's" motor ambulances which are attached to the French Army. Flowers will be sold from stalls throughout the week, and Messrs. GEORGE MONRO, LTD., 4, Tavistock Street, Covent Garden, have consented to receive gifts of flowers and fruit sent in aid of the funds. The organising secretary of the British Ambulance Committee, 23a, Bruton Street, would be pleased to give particulars to nursery firms willing to stage exhibits.

RESEARCH AT ROTHAMSTED. Mr. W. B. RANDALL, of Waltham Cross, has provided funds for the establishment of a new research post at the Rothamsted Experimental Station, and the committee have appointed Mrs D. J. MATTHEWS, M.Sc., formerly Miss A. ISGROVE. Mrs. MATTHEWS is an honours graduate of the Victoria University of Manchester, where she gained the Platt Biological Scholarship and the Dalton Biological Scholarship. She afterwards carried out important investigations at the Marine Biological Station, Plymouth. Her work at Rothamsted will include the study of some of the problems of soil sterilisation as it is now being carried out in certain types of nurseries.

FLOWERS IN SEASON.—We have received from Messrs. BARR AND SONS a collection of Tulips, representing choice named varieties of the May-flowering section. The vigour of the flowers was apparent, and the colours were magnificent.

U.S.A. GOVERNMENT TAKES OVER A SEED FIRM.—In view of the probable necessity for harvesting all kinds of seeds with the utmost economy next year, the U.S. Government has taken over the Nungesser-Dickinson Seed Company's establishment, at Hoboken, New Jersey. The price to be paid is said to be approximately $900,000. The firm is the largest of its kind along the entire Atlantic seaboard, and its annual output of seeds is therefore very great.

FLOWER POTS.—For several years prior to 1914 the garden and flower-pot industry in Great Britain was in a deplorable state owing to the cutting of prices and German commercial invasion, consisting of the organised attempt to "dump" the Teuton surplus stocks in England and, later, to introduce German pot-manufacturing machines. From the outbreak of the war, therefore, until quite recently, the supply of such pots has been considerably in excess of the demand, and nearly all manufacturers have accumulated abnormally large stocks; and even in the absence of official restriction on flower-growing a diminishing consumption of pots, due in part to lack of growers and the urgency of growing vegetables and fruit, has made but slight inroads on the surplus stocks on hand. The demand in 1916 was approximately one-fifth of the demand in 1914; the demand in 1917, one sixth. Manufacturers are therefore turning out about 12 per cent. of the usual pre-war quantity, and it is believed that the present supply would last for some time should further manufacture entirely cease. *Commerce Reports*, April 1, 1918.

HAILSTORM IN SURREY.—It is rare indeed that a hailstorm of such intensity and duration as that of Thursday, the 16th inst., visits this country. Fortunately it appears to have been singularly local, but in parts of Surrey the damage which it wrought will long be remembered. In the morning the gardens were at their fairest, and the Darwin Tulips had, after long lingering, opened themselves in full beauty. By the afternoon they were prostrate, their long and stately stems prone on the ground and the flowers battered and broken. Under the Gooseberry bushes the young berries—which may not be picked for sale—had been shot by the hail from their stems and lay in pitiable little heaps on the ground: so the trees will have had their thinning after all. Currants were treated in like wise, and Rose leaves were torn into fragments and strewn over the garden. Some of the plants of the rock garden weathered the storm unharmed. Phloxes, Aubrietias and Lithospermums took no hurt, but the Alyssums were knocked down and buried in the churned-up earth. Most curious of all was the effect of the hail on a border of Nepeta Mussinii not yet in bloom, which was, as it were, combed out like hair parted in the middle, and plastered down on either side.

KEW GUILD.—The annual general meeting of the Kew Guild will be held in the Lecture Room, Royal Botanic Gardens, Kew, on Saturday, June 8, at 6 p.m.

THE JERUSALEM ARTICHOKE.—It appears* that although a native of America, the Jerusalem Artichoke is more cultivated in Europe than in the country of its origin. Prof. COCKERELL points out the virtues of this food-plant, and statistics which he has collected show that its yield in America is high, reaching as much as 20 tons and upwards per acre.

LEATHER-JACKET AND WIREWORM.—The serious loss of cereal crops sown in recently-ploughed-up grass-land appears, according to the investigations carried out by the Food Production Department, to have been caused more by leather-jackets than by wireworm. Apart from heavy rolling and cultivation there appears to be no remedy for the leather-jacket, which, though always with us, is not generally present in such large numbers as appears to be the case this year. With respect to wireworm, a statement is sometimes made that a sure way to clear the soil of this pest is to sow Peas one year, followed by Beans the next, and it is claimed that, neither of these plants being attractive to wireworm, the pest is starved out.

* "The Girasole, or Jerusalem Artichoke: A Neglected Source of Food," by Prof. T. D. A. Cockerell, *The Scientific Monthly*, March, 1918.

We confess that we have no knowledge that this simple expedient does clear the soil of wireworm. Nevertheless, it appears to be a fact that Peas may thrive in soil infested with the pest. This, however, may be due to another cause. The Pea, when sown, sends its taproot straight down into the soil, and although the cotyledons remain in the soil the base of the stem tends to be pushed up near the surface. Presently, as the hairs of the root become infected with the nodule organism the growth of the main root is checked, and adventitious roots break out from the hypocotyl—the part of the axis near the insertion of the seed leaves. Hence, even though the main root be damaged, the spreading adventitious roots may still serve the seedling. Among the many terrible lessons taught by the war one of the most salutary is the value of knowledge as the realisation of our extraordinary ignorance of simple facts and phenomena, an understanding of which would be at the present hour of great value to the nation. The moral is obvious, and it is to be hoped that we shall "lay it to heart, so that when the opportunity arises to overcome these conspicuous and to-be-deplored gaps in our knowledge—as, for example, of the habits of leather-jackets and wireworms—may be mended. This, however, will never be done by confining the duty of discovery to a special caste of men, however well trained they may be. It can only be done if those who cultivate the soil themselves assist by keen observation and cautious trial to find out the causes of things. We shall have to organise our common-sense more than we have troubled to do in the past.

CELERY LEAF BLIGHT.—The treatment of Celery seed with hydrogen peroxide is recommended by the Board of Agriculture as a precaution against Celery leaf blight. A 20 volume solution is the best strength, but if that cannot be obtained a 10 volume solution may be used. The seed to be treated should be placed in a glass or earthen vessel and enough of the hydrogen peroxide poured into it to cover the seed completely. Stir the mass thoroughly so that all the seeds become wet. Allow the seeds to remain in the liquid for three hours, and then pour the liquid off and use it a second time if required. Spread the seed in a thin layer in the air before sowing. Do not return the seed so treated to the original packets, or some of the spores of the fungus causing the disease adhering to the paper of the packets may re-infect the seeds. If the plants become affected later, the disease may be checked by spraying with Bordeaux or Burgundy mixture. The spraying should be begun at the first sign of the disease and must be repeated if the first spraying does not check it.

WAR ITEMS.—Private JAMES S. ROBERTSON, who joined the Army in June last year, on reaching the age of 18, has died from wounds in France. Before enlisting he was in the gardens of C. E. GALBRAITH, Esq., Torregles, under Mr. W. HUTCHINSON.

—— Private MARTIN LEARMONT, Machine Gun. Corps, who was employed in the gardens of W. D. ROBINSON-DOUGLAS, Esq., Orchardton, Kirkcudbrightshire, under Mr. WILSON, has been posted as missing since March 21. He was 19 years of age.

—— Private G. PARKER, K.O.S.B., is reported missing since April 11. Prior to enlisting Pte. PARKER was gardener at Dalmonach House, Dumbartonshire, and was previously a member of the garden staff at Drumlanrig, Dumfriesshire.

CLERODENDRON UGANDENSE.

ONLY a few of the hundred or so described species of Clerodendron are grown in gardens, and two of the best for gardens are C. Thomsonae, one of the most beautiful of tropical climbers, and C. splendens, which may be called a crimson-flowered Thomsonae. These two species are African, as are the majority of the species. C. ugandense (see fig. 94) was described as a new species in 1909, when it flowered at Kew, where it was raised from seeds collected by Mr. M. T. Dawe in Uganda at 2,000 feet above sea level. It is quite as happy in the greenhouse as in a stove and trained against a rafter of the roof in No. 4 House at Kew it grows and flowers freely in the autumn. The peculiar merit of the species is in the colour of its flowers, which contains two shades of blue, the central, lip-like petal being violet, the other four lavender. The inflorescence is thin as compared with C. Thomsonae, and the habit of the plant is somewhat stiff. Still, twenty years or so ago some enterprising nurseryman would have sold many plants of it under some such description as "a new and beautiful blue flowered Clerodendron from the land of the Nile." Grown as a border shrub in warm temperate countries C. ugandense should be effective after the manner of Plumbago capensis. W. W.

FIG. 94. CLERODENDRON UGANDENSE: FLOWERS BLUE.

SOME OLD ENGLISH APPLES.

A FRENCH poet once asked "Where are the snows of yesteryear?" a rhetorical question which needed no answer. The Apple enthusiast sometimes asks in like manner, "Where are the Apples of our grandfathers?" The reply is that most of them exist, and curiously, tempered with patience, reveals many of them to the careful searcher. A few of these which came my way lately may be of interest to readers of the *Gardeners' Chronicle*. A good dish of Keddleston Pippin was submitted to the Fruit and Vegetable Committee at a recent meeting of the Royal Horticultural Society, and the flavour of the fruits was highly appreciated. Not much seems to be known of the origin of this variety. Hogg gives a short description of it in the 5th edition of his *Fruit Manual*, but is silent as to its history. The only reference I have found is in *The Gardeners' Magazine* for 1830, in a letter from Mr. T. Wood, of Chilwell Nurseries. In a list of table Apples he includes this variety, and says: "A Derbyshire Apple, originated (I believe) at the village from which it derives its name." It cannot have been very widely known, as it does not appear in the lists of fruits cultivated at Chiswick. However, the variety must have come rapidly into favour, as 22 dishes were exhibited at the Apple Conference in 1833. In appearance it may be described as a more golden Cockle's Pippin; the flesh is firm and juicy, very sweet, and well flavoured. This is decidedly one of the good old varieties which have been crowded out by larger but not, I think, better flavoured sorts. A very interesting fruit was sent to me from Cornwall

for naming, with the information that locally it was known as Gennet Moyle. A comparison with Hogg's description and the coloured illustration in *The Herefordshire Pomona* proved this to be correct, and I was very pleased to have met this old English variety after many years' search. This Apple dates back to Evelyn's day, and Worlidge refers to it as a "pleasant and necessary fruit in the kitchen, and one of the best cider Apples." Phillips the poet also names it in his poem on cider. It belongs to that class of Apples which root readily from cuttings, as Bradley said in 1727: "Dwarf trees, such trees as are apt to put forth roots. . . . as the Kentish Codlin, Genet Moil, and the like." In appearance the fruit is decidedly larger than that generally used for cider, and a small fruit of Maltster would much resemble it. The flavour is pleasant; I could not recognise the "sweetest honyd taste" discovered by Phillips, but poets must be allowed their licence. The name presents an interesting philological problem. Gennet was a small Spanish horse, and Moyle a mule, and a suggestion has been made that a hybrid origin is thus indicated. Recent authorities derive Gennet from the French "Jeannette," and this seems more probable. The use of Jeannette as a name for a Pear in contrast to Pear Robert, is established by a poem of the Middle Ages published by the Wharton Society, but as it is of the class called "curious" by booksellers it cannot be quoted here. Our Juneating or Jenneting is likely to be a diminutive of Gennet rather than from Joanetting, as suggested by Hogg, and the June Eating theory has long been abandoned by all competent authorities. We should, therefore, spell this Apple Genneting, or Jemeting.

A very interesting collection of Apples from an old orchard was shown by Mr. Bayley, of Revelstoke, Slough, during the autumn, at the Drill Hall, and two varieties, the Old Pearmain and Orange Pippin, attracted my attention. The name Pearmain has been used in England since 1200, and it would be extremely interesting to be able to find this original type. The fruit shown by Mr. Bayley agrees very closely to that described by Hogg, and is larger than the Pearmain type, as instanced in Adams's Pearmain, Mabbott's Pearmain, and others cultivated at the present day. I should like to think that this fruit was the variety of the 15th century, but on referring to Knight's *Pomona Herefordiensis* quite another fruit is figured as the "Old Pearmain," a cider variety, of much smaller size and quite different in colour and shape. There for the present the problem must be left. Mr. Bayley's other fruit, the Orange Pippin, was a fine large Apple of Blenheim Pippin character, rather the style of Bedfordshire Foundling, but more golden and with a redder cheek. Considering the tree from which this Apple was gathered is estimated to be over a hundred years old we may assume that from younger trees the fruits would be even larger. The Orange Pippin I have seen before is that figured by Hogg and Bull in the *Herefordshire Pomona*, known also as Isle of Wight Pippin. This is a smaller fruit, of about the size of Cox's Orange Pippin, but of flatter shape, and the eye is a deepish basin. It may, therefore, be that there are two Orange Pippins, the large one shown by Mr. Bayley after which Blenheim was named, and the smaller one, or Isle of Wight Pippin, which served us as the arch-type of Mr. Cox's seedling. In any case, Mr. Bayley's Apple seems worthy of further trial, and I am indebted to him for a few grafts for my collection.

Pine Golden Russet was very good last season, and though hardly in the category of forgotten fruits, it is one that deserves bringing to the notice of those who are more anxious for flavour than size. I much enjoyed giving fruits of this variety to some of my Apple-loving friends and watching them take the first bite. Astonishment and appreciation were happily mingled, and most of them remarked "there is nothing like it for flavour." A musked honey is the nearest I can venture to a description of its flavour. Of obvious Golden Pippin descent, it is of the Adams's Pearmain shape, and the skin a thin golden russet; it is in season from October to December. It is unfortunate that there are so many "Pine" Apples that one is apt to get the names confused, no fewer than four being included in Hogg's *Manual*. *E. A. Bunyard.*

A GARDENER-FARMER.

THE column on farm matters published each week in the *Gardeners' Chronicle* is of great interest to the many gardeners who have the dual responsibility of managing the garden and home farm, and is especially useful just now when advice on such matters is doubly needed. The writer of the notes, Mr. Edwin Molyneux, is well known as a successful gardener and able writer on gardening, and is, in addition, one of the best farmers in the country. Some impressions gained during a recent visit to Swanmore Farm may be of interest to readers. As might be expected from one whose earliest activities lay in the direction of matters horticultural, he makes a feature of commercial fruit-growing. The Apple orchard is six acres in extent. The trees are in the best possible condition, full of promise, and skilfully pruned; the yield last year was 1,700 bushels. The trees include a large number of varieties, many of which are only grown for comparison. The sorts which do best and are most prized are Cox's Orange Pippin, Lord Grosvenor, Norfolk Beauty, Ben's Red, Allington Pippin, Lady Sudeley, Cox's Pomona, Victoria, Grenadier, Mère de Ménage, Bismarck, Blenheim Pippin, and Bramley's Seedling.

Two acres of Cob nuts and Filberts give profitable returns in most seasons. The vineries which Mr. Molyneux planted about forty years since, and have long been noted for their fine Grapes are giving bunches as good as they produced a few years after planting, the promise for this year being all that could be desired.

The farm is situated in one of the most pleasant parts of Hampshire, and consists of about 300 acres, of which 600 are arable. The soil is variable, and includes a great portion of stiff and tenacious land, interspersed with soil of a lighter texture, the latter being of a chalky and stony nature. I was impressed with the high cultivation of the farm, the cleanliness of the land, the magnificent appearance of the various crops, and the fact that every particle of ground was utilised to the full. There are miles of well-kept hedges and perfectly maintained fences; the hedges do not, as is so often the case, occupy acres of valuable ground, but are kept within the narrowest bounds, yet sufficient to give shelter to crops and animals.

There are 100 acres of Wheat, and no fewer than 30 new varieties are under trial; 120 acres of Oats; 50 acres of Barley; 12 acres of winter Barley; 12 acres of Rye; 100 acres of Turnips and Swedes, 5 acres of Cabbage; 15 acres of Potatos; 10 acres of Mangolds; 2 acres of Onions; 2 acres of Sunflowers; 3 acres of Sugar Beet; 1 acre of Maize; with the usual Vetches, Sainfoin, Mustard, Clovers, grasses, etc., 150 acres of hay, and, in addition, many acres of Down land. The Down grass land shows in a very notable way the value of basic slag. Some five years ago a portion of the grass was dressed with this fertiliser, and the difference between treated and non-treated land is most marked. Where it was used, the turf is green, luxurious, and full of Clover, whilst untreated ground has a poorer looking appearance.

Sheep comprise a very valuable registered flock of Hampshire Down consisting of 400 ewes and a magnificent lot of lambs, many fit for killing. Pigs form an important item on the farm, and these are being largely increased in numbers: the favourite breed is Large Yorkshire White crossed with a Middle White boar.

Swanmore has long been noted for its splendid quality butter; the dairy cows include a herd of the pure Guernsey breed, and no fewer than 250 customers are supplied with butter.

In pre-war times fifteen pure breeds of poultry were kept, and 2,000 chickens reared annually, besides many ducks and large quantities of turkeys; no fewer than 50,000 eggs were collected yearly.

Another important industry at Swanmore is that relating to coppice work. About 20 acres of underwood is cut annually, and supplies material for 300 dozen hurdles made on the estate, 60,000 thatching spars, 10,000 faggots, the making of birch brooms, and various other uses.

Like many other land owners, Mr. Myers is having a large part of his beautiful park ploughed for the purpose of increased food production, and at the time of my visit German prisoners of war were employed at this work. *Visitor.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

DAVIDIA INVOLUCRATA. This Western Chinese tree has produced a few flowers (floral bracts) this year at Tortworth. Three plants were purchased from Messrs. Jas. Veitch and Sons about 15 years ago. The tree now in flower was planted in the kitchen garden about 6 feet from a 12-foot wall which faces south-east. It is grown somewhat in bush fashion, but attains the height of 26 feet. *J. Banting, Tortworth Gardens, Falfield, Gloucestershire.*

THE GRAPERIES OF BAILLEUL (see p. 178).—The Grapperies du Nord were founded by M. Anatole Cordonnier, whom I have known personally for more than 30 years. M. Cordonnier was originally a manufacturer of dress material, but subsequently interested himself in the forcing of choice fruits. I doubt very much whether his Grapes ever came in quantity to the London market, as your paragraph states. One consignment was sent 28 or 29 years ago, and the result was so unfavourable that I do not think M. Cordonnier cared to repeat the experiment. The eldest son of the proprietor spent a short time at Thomson's, of Cloverfords, to gain an insight into his method of Grape growing. M. Henri Fatzer was also closely associated with the proprietor of the Grapperies du Nord and planted at least 2,000 of the vines there. M. Cordonnier paid many visits to vineries in Belgium, England, and the Channel Islands, to get hints and ideas for the most advantageous construction of his great vineries, which were a success from the first. When the French authorities saw what an important local industry had been created by its originator, they gave him the Medal of the Legion of Honour, and placed a strong protective duty on Grapes, which practically excluded the Belgian Grape growers from the French markets. *C. Harman Payne, 195, Wellmeadow Road, Catford.*

HOP-SHOOTS AS AN ARTICLE OF DIET.—"The thrifty Belgian" is credited on p. 163 with a full appreciation of the toothsomeness of the young shoots of the common Hop when well cooked. Apart from all published records of its use as a pot-herb, I can testify to its appetising qualities, both from observation and consumption. Hop tying was one of the few farming operations performed by women in East Sussex in my young days. This was effected by rushes: two or three "bines" being attached to each pole, and the rest of the shoots removed while still quite young and short. These surplus shoots, often numerous, were the perquisite of the tyers, who cooked and ate them, or sold them for a few pence the bundle. Buyers were not wanting, and, carefully cooked, in the same way as Spinach, young Hop "bines" constituted a delicacy which I would fain taste again. *W. Botting Hemsley.*

SOCIETIES.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

May 13.—The monthly meeting of this society was held at the R.H.S. Hall on the 13th inst., Mr. Arthur Bedford in the chair. Five new members were elected. Five members were allowed to withdraw interest amounting to £18 17s. 8d., and three members over the age of 70 years withdrew the sum of £87 0s. 7d. The sum of £103 7s. 7d. was passed for payment to six nominees of deceased members. The ordinary sick pay for the month amounted to £70 7s. 8d.: State section, £22 19s. 2d., and maternity claims £7 10s.

CROPS AND STOCK ON THE HOME FARM.

Cabbage

Attention should be given to raising a good batch of healthy Cabbage plants from the seed sown in April. The Turnip fly often attacks young Cabbage plants. In a small garden preventive measures can be readily applied, but on a farm it is not such an easy matter. One of the best preventives is to cover drills or beds which have been sown broadcast with short grass cut from the lawn, completely covering the seedlings. As the grass wilts the plants push through, and when they get so far they are usually beyond the stage when they are harmed by the fly. Soot may also be applied to ward off attacks. The seed should be sown in drills rather than broadcast, as the stirring of the soil between the drills with the hoe does much to hasten the growth of the plants.

Directly the plants are large enough to handle they should be placed in their permanent quarters in rows 2 feet 6 inches wide, the plants 2 feet apart. Choose dry weather for planting, as slugs are not nearly so troublesome to the plants as they are when planting is done during showery weather.

The Apple Orchard

Apple blossom this year is thin, excepting on trees that had but a thin crop last season. Where the trees are growing thickly together do not dig the ground between them but keep the surface free from weeds. If this has not hitherto been done, have the surface cleaned, raking the weeds and grass in heaps to dry. When the heaps are thoroughly rotted, they can be again spread over the surface, but it will be as well first to apply a dressing of Peruvian guano at the rate of 12 cwt. to the acre, basic slag 8 cwt., superphosphate 6 cwt. The present may not be the best time to apply these stimulants, but better now than not at all, and most trees need assistance after their heavy crops of last year.

As yet there are few signs of caterpillars or green flies attacking the leaves or flower-trusses, but it is wise to spray the trees as a preventive before the blooms burst.

Newly planted trees that are showing blossom should receive every encouragement to make growth freely by surface stirring of the soil and removal of all blossom.

Wireworm in Oats

There is still time to apply remedies to check the ravages of wireworm in late-sown Oats, of which there is a considerable acreage, especially on newly broken up grassland. Firmness of soil is a protection against wireworm, but newly-ploughed grass land cannot be made sufficiently firm to resist an attack, for as the turf decays it subsides, leaving hollow places. The best remedy is so to accelerate the growth of the Oat plant to enable it to get beyond the stage of attack. Nothing aids the growth so much as nitrate of soda or sulphate of ammonia sown evenly over the plot at the rate of 1 cwt. per acre.

Onions

Onion seed has germinated remarkably well, and especially under glass, this spring, quite 98 per cent. The plants from the March sowing in the open look well. Surface stirring of the soil and a light dusting with soot will be an advantage, accelerating growth, which is all in favour of early ripening of the bulbs. The advantage of sowing the seed in boxes in cold frames is apparent. This system is being commonly applied. Apart from the question of labour, the method possesses many other advantages, such as the assurance of an even plant, an early start, larger bulbs, and a prospect of escaping the Onion maggot.

The land having been thoroughly prepared, all that it needs now is to harrow it over or cultivate the surface to get rid of weeds, that rapidly spring up at this season. When the plants are large enough to handle they should be dibbled in rows made one foot apart, putting the plants 4 inches asunder in the rows, taking care that the bulbs are not buried, but making the roots quite firm in the soil.

Maize.

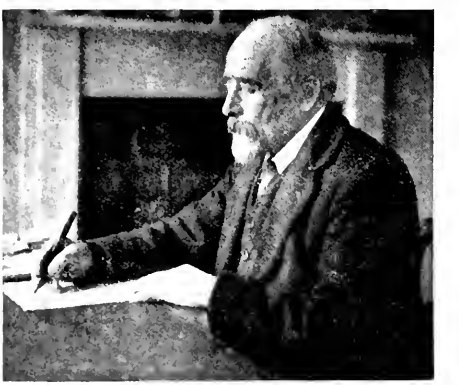
A difficulty is being experienced in obtaining the Giant Horse Tooth variety of Maize, which is the best to grow for cattle, as giving the heavier bulk of food. I am now growing Giant Virginian. Maize does not require any difficult preparation of the land. Any clean plot will suffice. If farmyard manure can be spared plough this in at the rate of 15 tons per acre, either now or in the autumn. Some drill the seed, but my experience is that this plan enables rooks to take too much of the seed when it is shallowly buried. I sow now in and after each plough furrow; that is, the rows are 8 inches wide. The seeds are strewn along some 6 inches apart. If farmyard manure was not ploughed in I sow along with the seed superphosphate at the rate of 4 cwt. per acre. The ploughing is not more than 3 to 4 inches deep, which ensures perfect safety from rooks. The surface is harrowed to produce a fairly fine tilth, and if the soil is loose a light roller is drawn over it to consolidate the whole. In three weeks' time, as the first batch of weeds show through, especially Charlock, the harrows are again drawn over to kill the weeds. *F. Wallace.*

The Vitality of Charlock Seed.

I can corroborate Mr. Macqueux's statement on p. 151 about Charlock seed lying dormant for years in the soil, and then springing up in abundance where corn crops are sown on grass land. Where the soil is good, and cultivated on the principle of a rotation, it is often left for three years in grass; yet when ploughed up and sown with Oats in March the fields are a sheet of yellow during June and July, resembling Turnips grown for seed rather than corn. In the north east of Aberdeenshire many years ago, steam ploughing made a good start, but has been doomed to failure ever since. I have been repeatedly told that this was due to the fact that the steam plough, going deeper than the ordinary one, turned up a far greater quantity of Charlock seeds, and rendered the land considerably less productive of corn than previously. The farmers bear that grudge against steam ploughing to the present day. Charlock is a bad a weed in the far north as in the south. It is known as "Skelloch" over a wide area of the northern part of Britain. The White Mustard (*Brassica alba*) is prevalent over all the lands overlying the chalk formation in Surrey and, at least, some parts of Kent, yet it never, in my observations, dominates the corn to the same extent as Charlock, even where ploughing is done by steam. Spraying for the destruction of Charlock was unknown during the period to which I refer. Spraying with copper sulphate will destroy the weed if the mixture is applied when the plant is in a young stage, the proper time being when the first rough leaves have formed. The corn crop is not harmed by the copper sulphate. *J. F.*

Obituary.

William E. Bear.—It is with much regret that we record the death of Mr. William Edwin Bear, of Magham Down, Hailsham, better known to our readers as *Southern Grower*, whose monthly notes on "The Market Fruit Garden" have been a feature of the *Gardeners' Chronicle* for several years. He passed away at his home on May 15, in his 78th year, after an illness lasting only five days. Before Mr. Bear turned his attention to horticulture he was engaged in agriculture at Thorpe-le-Soken, near Colchester, from 1864 to 1878. He had not been farming for long before he began to contribute to the agricultural Press, particularly to the *Mark Lane Express*, then the best journal of its kind. His contributions met with such a good reception that, upon the retirement of the editor, Mr. Henry Corbet, owing to ill health, he was invited to accept the position. The demands of this and other journalistic engagements made it necessary for Mr. Bear, in 1878, to give up farming and reside near London, where he remained for twenty years. During that time he reached the front rank of agricultural journalists. His most notable engagement was that of agricultural correspondent of *The Standard*, which he held for nearly twenty years. At the same time his work appeared frequently in the *Quarterly* and several other monthly reviews, also in the



THE LATE W. E. BEAR.

Journals of the Royal Agricultural, Highland, and Bath and West of England Societies. He was a regular contributor to *The Leeds Mercury*, *Agricultural Gazette*, *Live Stock Journal*, *Economist*, and *Land Agents' Record*. He established the Farmers' Alliance in 1879, and acted as its secretary during the active period of its existence. About 1893 he was appointed assistant commissioner for the Royal Commission on Labour, and in 1893-9 he visited the chief horticultural districts of the country at the request of the Royal Agricultural Society, to report upon flower and fruit farming in England for the Society's Journal. It was this latter undertaking which decided him to take up fruit-growing for market. During his residence near London gardening formed his chief relaxation, and he had considerable success in the cultivation of fruits and vegetables, but he disliked town life, and always longed to return to the country. In 1900 Mr. Bear purchased Magham Down Farm, near Hailsham, Sussex, and began to plant it with fruit trees and bushes. Gradually, as the farm gained in prosperity, Mr. Bear relinquished agricultural journalism and devoted himself entirely to horticulture. Latterly his notes for the *Gardeners' Chronicle* were practically the only journalistic work he undertook.

Mr. Bear brought a vigorous personality and remarkable energy into all that he undertook. In his relations with those who worked for him he was exacting, but was liked and esteemed for his justice.

MARKETS.

COVENT GARDEN, May 22.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate not only from day to day, but occasionally several times in one day.—Eds.

REMARKS.—Longer supplies of home-grown flowers are reaching the market. Double White Narcissus flore pleno, Narcissus poeticus, and double White Stock are the leading lines in white flowers. The hot weather has practically finished the Tulips for this season. A few coloured Paeonies are offered for sale. Small quantities of white bean grown Gypsophila find a ready sale. A few boxes of white and coloured Gladiolus are arriving from Guernsey. These consignments suffer in quality owing to the heat. Spanish Iris being almost unsaleable. A few Lilium longiflorum and Richardia (Arums) are selling at high prices. Cornflowers, blue and pink, and single-coloured Pyrethrums, are the latest arrivals.

REMARKS.—Owing to the warm weather, fruits and vegetables grown indoors are more plentiful. They include Strawberries, Melons, Peaches, Figs, Nectarines, Black and White Grapes, Dwarf Peas and Beans, Broad Beans, New Potatos, Tomatos, Vegetable Marrows, Mushrooms, and Cucumbers. Asparagus from all well-known sources is plentiful, cheap, and good. Outdoor vegetables and roots are more scarce. Salads are plentiful and moderate, but Lettuces are rather dear.—*E. H. B., Covent Garden Market, May 22, 1918.*

DEBATING SOCIETIES.

BATH GARDENERS'.—Mr. T. Perfect (chairman) presided at the monthly meeting of the Bath Gardeners' Debating Society at the Foresters' Hall, on the 13th inst., when a paper was read by Mr. J. Boulter on Diseases of the Potato. Mr. Boulter stated that the Potato disease reached this country from America in the early forties, and visited Ireland in 1847.

GARDENING APPOINTMENTS.

Mr A. Grant, as Gardener to Mrs. Smith, Finches, Landfield, Sussex.

Mr J. P. Hall, as Gardener to H. Coleman, Esq., Greystoke, West Didsbury, Manchester.

Mr. William Hutchinson, recently Gardener to C. E. Galbraith, Esq., Terrugles, Kirkcudbrightshire, as Assistant Ground Officer at H.M. Factory, Gretna.

CATALOGUE RECEIVED.

Australia.

C. A. Nobbles & Sons, Gumbrook Nurseries, Emerald, Victoria, Australia.—Fruit trees.

ANSWERS TO CORRESPONDENTS.

French Journals. *J. B. M.* Probably the papers which will best serve your purpose are the *Revue Horticole*, Rue Jacob, 26, Paris 6e; and *Le Jardin*, 84, Rue de Grenelle, Paris, but they are not weekly journals, both being published for the present only once a month. *L'Horticulture Française*, 6, Rue du Débarcadère, Paris, is a trade market gardening journal, but only appears four times a year, at somewhat irregular intervals.

Fungus Growth on Bottled Cherries: *Correspondent.* The foreign growth on the top of your preserved Cherries is the sterile mycelium of a fungus; it cannot be named in the stage you send.

Lettuces Injured: *Allotment.* Creosote fumes are very destructive to plant life, and it is highly probable that the fumes of the creosote have caused the damage to the Lettuces, especially as the injury is purely external, the heart of the plants being perfectly sound. As regards the Currant bush being unaffected, this is easily to be understood, as, when the fence was first dressed, the leaves had not developed, and the bark would protect the shoots from the fumes. By the time the foliage was fully expanded the fumes would, to a great extent, have passed off into the air.

Liliums Unhealthy: *S. E.* The trouble is not due to the fungus Botrytis or other organic disease. The diseased condition is probably the result of the inclement weather of early spring, when cold north and north-east winds prevailed.

Military Service: *G. W.* You could appeal on the grounds of being a food-producer, but the tribunal will not be bound to exempt you on these grounds. If your application fails, however, you can ask permission to appeal.

Names of Plants: *H. White.* 1, Artemisia absinthium (Wormwood); 2, Tanacetum vulgare (Tansy); 3, Melissa officinalis (Common Balm); 4, Marrubium vulgare (Common White Horehound); 5, Origanum vulgare (Common Marjoram); 6, Tanacetum vulgare crispum (Crisped Tansy); 7, Mimulus glutinosus (sometimes named Diplacus glutinosus); 8, Rochea coccinea (sometimes named Kalosanthes coccinea); 10, Erlangea tomentosa; 12, Impatiens Holstii; 14, Begonia Gloire de Sceaux; 16, Ficus Parcellii. *W. L., Kettering.* Rehmannia angulata. — *Edwin Dunham.* 1, Rhododendron grande; 3, Lonicera tatarica.—*E. A. E.* Ornithogalum arvense; 2, Exochorda grandiflora; 3, Phillyrea media; 4, P. angustifolia; 5, Amelanchier canadensis; 6, Spiraea chamaedrifolia.

Protected Occupations: *T. L. I.* Apply to your local National Service Tribunal, or write direct to the Ministry of National Service, Hotel, Windsor, Victoria Street, S.W. 1.

Pruning Lilacs: *T. H.* Lilacs do not need pruning in the usual sense of the word, but your plants badly need thinning of their shoots. Remove all small, weakly shoots now, leaving only the strongest and best-placed. Some of the weaker of the older wood should also be cut out. After doing this give the roots a good dressing of manure and plenty of water during dry weather. Free flowering next year depends on the development of strong, well-ripened wood made in the present year, and only drastic thinning out of the weaker wood will ensure this result.

Red Spider on Peach Trees Indoors: *Rushbrook.* Syringe the trees freely with clear water. The pest spreads rapidly in hot, dry conditions.

Scaring Birds from Cherries: *E. A. P.* As your trees are too large to net, and you do not wish to use a gun, we would suggest that you purchase a mechanical sound-scare, of which several makes are to be had from the horticultural sundriesmen.

Tenants' Rights: *G. B.* Unless you have a clause in your lease expressly permitting you to remove plants, including fruit trees, from your garden when you leave the cottage, you are not legally entitled to do so, nor can you claim any compensation for the work and material's you have expended in enriching the garden. You can, however, remove the rock garden, if this is composed, as we assume, of rocks and stones resting on the ground, and if they were purchased by yourself.

Tulips Diseased: *C. L., K. C. A.* The bulbs are attacked by Botrytis parasitica, a common disease of Tulips. Pull up and burn all infested plants, which may be identified by small, brown, velvety patches which will be found on the stem, leaves or flowers; and sterilise by burning the soil around the place where they were growing. It will be safest to remove all the bulbs from their present position, and plant the healthy ones in ground where no bulbs have hitherto grown.

Gardeners' Chronicle
No. 1640.—SATURDAY, JUNE 1, 1918.

CONTENTS.

ILLUSTRATIONS.

AN EIGHTEENTH-CENTURY LONDON SEEDSMAN.

WHILST nearly every phase of horticulture has been written about, and in some instances extensively, there is at least one almost entirely untouched, and of which, unfortunately, most of the scanty data which did exist is no longer procurable. I refer to the business of the seedsman, who acted, in the old time as to-day, as the middle man between the grower and the consumer, but a middle man with expert knowledge. Carlyle has told us that in these days ten ordinary histories of kings and countries were well exchanged against the tenth part of one good history of booksellers. And it may be asserted with equal confidence that a good history of the seed trade and seedsmen would be as full of interest and romance as that of any other business.

The seedsman, like the bookseller, of yesterday and to-day, issued catalogues of his wares, his plants and his seeds. These lists, unfortunately, have not been preserved with the same care as those of books. They were kept for a season, perhaps till the new ones appeared, and then destroyed. Very few have survived, and these only by some curious accident; and even so, their historic interest and importance in the annals of agriculture and horticulture do not seem to be fully realised. They are, in truth, essential to any historic narrative on the development of the cultivation of the soil.

It has been my good fortune recently to discover an early 18th century seedsman's catalogue in a folio volume of pamphlets; and it is perhaps one of the earliest to survive. It is "A Catalogue of several sorts of Grass Seeds, sold by Nathaniel Powell, at the King's Head near Fetter Lane end, in Holborn, London." Nathaniel Powell is quite unrecorded in any bibliography of agriculture or horticulture, but he must have been one of the leading London seedsmen for half a century at least. Attached to the catalogue—it is really not a catalogue at all as we understand the term to-day, but a series of cultural directions which consists of four pages, foolscap size, is "A Short Account of the Improvement of Land by several sorts of Seeds," sold by the same seedsman, and this also consists of four pages, foolscap size. The format and typography of the two undated pamphlets at once place them in the early years of the 18th century. The second of the two publications contains the following interesting "testimonial" from quite the most esteemed writer of the day on gardening and allied topics: "To Mr. Powell, seedsman, Holborn. Sir, I have perused your Treatise of Grass seeds, and the Improvement of Land by them. I think it a Piece of great Use, and is perfectly agreeable to my Practice.—I am, your most humble servant, R. Bradley." Bradley died in 1732, and the catalogue must have been issued several years previously. Powell's name as a seedsman at 59, Holborn, appeared in the London directories up to 1771, and possibly a little later; my set of these is unfortunately not complete, but it disappears entirely in 1777; and it may be that the Nathaniel Powell whose death is recorded in the *Gentleman's Magazine* as having taken place at Bristol on March 1, 1773, is identical with the Holborn seedsman.

Judging from this example, the early seedsmen concerned themselves more with practical directions than with varieties of seeds in their catalogues. Varieties, it is true, were very few indeed in every branch of farm and garden produce, for the science of selection in such matters was as yet almost unknown. The catalogue deals almost entirely with "Trefoil, Clover, Sainfoin, Rye grass and Lucerne." The age was evidently one of experimenting, and from the full cultural directions it is clear that Powell was a practical man. Whilst all the crops with which he particularly deals had been cultivated for many years, it is a reasonable inference that their qualities were by no means universally recognised by English farmers. Trefoil, "otherwise called Nonsuch seeds," certainly is more a boom at present in the catalogue and lists as in other uses the writer emphasises the importance of "clean seeds" "every seed separated from the husk wherein it grows." Trefoil was especially recommended for all land "naturally kind for corn and unkind for grass" and "so planted, would be worth 30s. to 5 per acre. It would, claims Mr. Powell, make clay, chalky, rocky and hilly land worth only 10 groats an acre yield a return of from 15s to 25s. per acre." Trefoil was especially recommended for cows as producing milk in greater quantity and of better quality than anything else, whilst the butter and cheese will be of a delicate yellow colour. Its superiority over Clover grass is frequently emphasised but if "you are resolv'd to sow Clover the safest way is to mix one half of Trefoil with it." Twelve pounds were regarded as sufficient for an acre, "unless the ground be rough."

Although Sainfoin (S. Foyne or Holy hay) had been cultivated early in the 17th century, it was not until many years afterwards that it was extensively grown. In 1659 there is a record of a farmer having put down about 70 acres of it. It was still regarded askance when Powell wrote. He pointed out that it has "thriven so well and is so great an improvement on our Barren lands where others will not; it being also Natural to our *Tomorous Rusticks* not to hazard Lands that will yield them any considerable Advantage any other way, on any New Method of Husbandry: in several Places there are Pieces of St. Foyn that hath been several Years Growing on poor Lands, hath so far Improved the same that a *Noble per acre*, 20 acres together, hath been constantly worth 30s. per acre, and yet continues in good proof." In his second pamphlet Powell states that the first considerable improvement made in England to Sainfoin was in and about Northamptonshire on the most barren gravelly grounds where it yielded such valuable crops that many farmers elsewhere were induced to try it, whilst "in Kent it is in great Perfection upon chalky gravel, and it is of Extraordinary Duration in all places where it is sown, even in some Parts where it has stood twenty years it yet brings as valuable Crops as at the first." The seed being large and light, an acre of ground "can require four bushels.

Land which is not good enough for Trefoil, Clover or Sainfoin can be laid down in Rye grass (Rey or Everlasting grass), it "being proper for all clays or other cold or sowre wet fenny lands." Dry "chalky, stony lands" not worth ten groats an acre, if sown with these seeds, will be as good as pastures or meadow lands at a mark an acre "a curiously late use of the words groat" and "mark." It may be sown with Barley or Oats in the spring, or in the autumn, when the Barley or Oat stubbles should be harrowed in before the seeds are sown, "harrowing with bushes the harrow" is advised.

Lucerne, or as it was called, "La Luserne," has had quite a number of pamphlets written about it. Powell praises it as "an excellent Fodder, and by some preferred before St. Foyn, as being very advantageous to dry and barren ground." He tells us that lean horses are suddenly fat with it, and that it causes "abundance of milk as much boasts but it must be given at first with Caution." One acre, he tells us, will keep three horses all the year long. In his second pamphlet Powell devotes a paragraph to "French Furze or Goss," which he advocates sowing on sandy and gravelly soils well exposed to the sun, it making "an excellent cover for young Plantations of Wood or Timber Trees, by defending the young Plants from being injured by Cattle." He tells us further than it is sown frequently in Devonshire and Oxfordshire, and that it is worth £3 per acre when it is cut.

I have selected a few of the more salient points which suggested themselves in reading this quaint treatise of a seedsman of two centuries ago. How far or to what extent the directions set forth by Nathaniel Powell are followed to-day need not now be discussed. That these directions were the outcome of practice and close observation there can be no question. One would like to know more of Nathaniel Powell; at all events, it is a pleasure to add a new name to the list of English writers. But it was not to farm seeds alone that Powell confined his attention; for we read at the end of his catalogue: "At the aforesaid Place you may be furnished with Riga or Dantzick Flax seed, Buck or French Wheat. Also all sorts of Garden Seeds, Fruit and Forest Trees and Plants; likewise all sorts of fishing and fowling Nets, and all sorts of Tackle, at reasonable Rates." Perhaps at some future time other catalogues of Mr. Powell's activities, more especially in the way of garden seeds and plants, may be unearthed in long forgotten and neglected volumes of miscellaneous pamphlets. *Roberts.*

PLANT NOTES.

PAEONIA CAMBESSEDESII.

IN reply to Sir Herbert Maxwell's note on the above plant (p. 205), I may say that it comes from the Balearic Isles, and was introduced into this country by Miss Geoghegan, who has a charming garden in the neighbourhood of Dublin. She very kindly gave me several specimens of that interesting and rare species; it has flowered well here, and I was able to send a little of its seed some years ago to the Royal Horticultural Society, in the hope that it might be more generally known. The plant is quite hardy in this part of Ireland, and is a decided and valuable addition to the garden, as may be seen from the excellent description given by Sir Herbert Maxwell. Miss Geoghegan, I may add, has also brought to this country from the Balearic Isles the true Helleborus lividus, which was figured and described in the *Botanical Magazine*, July 1, 1903, tab. 7,903, from material supplied by her. I do not, however, know where any living specimen of the last named plant is now growing, for most, if not all of the plants, seem to have disappeared from cultivation. *John Ross of Bladensburg, Rostrevor.*

ENCEPHALARTOS ALTENSTEINII.

IN *Gard. Chron.*, September 25, 1876, p. 392, the late Dr. M. T. Masters stated that E. Altensteinii is synonymous with E. Vroomii and Zamia elegantissima of Continental gardens; according to the *Botanical Magazine*, t. 7,162 (1891) another name for this South African Cycad is E. Maranui. There are magnificent examples of E. Altensteinii in the Palm House at Kew, and the illustration in fig. 95 shows a female plant with two cones. Of the seventeen species of the genus known, all of which are African, this is the largest and most striking. It has a stem a foot or more in diameter, and leaves 5 feet long; the female cones are 16 inches long, 2½ feet in circumference, and when ripe they are bright red and yellow. The male cones, which are also produced by plants at Kew, are much smaller, being only some 6 inches long and less than 2 inches wide. A plant of this species, growing in a valley in Natal, is said to have had a trunk 16 feet and a head of five branches, each with a great rosette of leaves. There are many large examples of this Cycad in cultivation in European gardens, and at the great exhibitions, such as the quinquennials at Ghent, they are wont to be displayed (at considerable expense, for they are awkward plants to transport), to the wonder of many who were uncertain whether to look upon them as Palms or as Ferns. Dr. Masters spoke of them as "animated fossils, Rip Van Winkles of the vegetable world." They are suitable only for large conservatories. Their leaves are exceedingly durable, and they are quite easy to keep in good health.

FIG. 95.—FEMALE CONES OF ENCEPHALARTOS ALTENSTEINII.

ON INCREASED FOOD PRODUCTION.

BROCCOLI.

BROCCOLI should be planted as soon as the seedlings are of sufficient size for removal. On most soils Broccoli may be planted between rows of Potatos; should, however, ample ground be available, choose an open position where the soil has been well manured and trenched. Whichever method is followed, the soil must be rich. Broccoli succeeds best where the soil is made quite firm, and this is particularly necessary where the soil is of a light texture. Planting is best done during showery weather; if the seedlings have been previously pricked out they should be shifted with a trowel, but where they have been left in the seed-beds planting is best performed with a dibber. Plant in rows made 2 feet to 3 feet apart, according to the variety, and allow the same distance between the plants in the rows. Water the roots, and apply a top-dressing of nitrate of soda at the rate of two pounds per rod. If the Broccoli are intercropped between Potatos apply the fertiliser as soon as the Potato crop is removed. Kale, Savoys, and Brussels Sprouts should be treated in the same way, and the sooner they are planted now, the better. *James A. Pearce.*

PARSNIP CANKER.

IN an article on "Diseases of Parsnips," by Mr. A. D. Cotton, published in the *Kew Bulletin of Miscellaneous Information*, No. 1, 1918, it is stated that canker of Parsnip, or the decay of the upper part of the root in late summer and autumn, has recently been on the increase, and is responsible for serious losses. The disease is due primarily to a physiological phenomenon which causes the surface tissues to become ruptured or cracked, and not to the invasion of a fungous parasite. Decay also follows as a result of a severe injury caused by Carrot fly, slugs, and other pests, but in the areas investigated such injury was scarce. Cracking takes place during the growing season, especially if rains follow a dry period, the portion involved being the skin, i.e., the periderm and the outermost layers of the cortex. The cracks, which for the most part run horizontally around the upper part of the root but also in a vertical direction, are from ¼ to 2 inches long and gape open, exposing the soft inner tissues.

The "canker" or decay which follows is shown to be the result of the inability of the Parsnip to form a layer of cork to heal the wound. Though the outer walls of the exposed cortical cell become suberised, and few cell-divisions occur, no definite phellogen is formed, and the growth-cracks are not protected as they are in the case of Carrots, Swedes, and other fleshy roots. The suberisation of the outer walls is insufficient to exclude micro-organisms, which enter, probably by means of inter-cellular spaces and fissures due to drying, and more or less rapidly destroy the tissues of the root. Though canker is worse in some localities than others, it appears to occur in all districts if rupturing of the skin takes place. No one micro-organism specially connected with the decay has been isolated.

The conditions leading to crack-formation suggests that whilst such cracks are due to an unequal rate of growth, the inner tissues growing more rapidly than the outer, and are governed very largely by weather conditions, their formation may be favoured by certain methods of culture, namely, over-manuring, neglect of liming, and early sowing (inducing premature ripening). The variety of Parsnip grown may also be partly responsible, a form of high quality, with bulky top, abundant flesh, and small core, being very largely cultivated in the worst infected areas.

Control measures consist in rectifying the faulty methods of culture alluded to, and the use of potash and common salt with a view to retarding maturation.

In order to reduce the amount of surface-cracking and canker the following treatment is recommended:—

(1) Too rich a soil must be avoided. (2) Late sowing should be adopted. Such observations as it has been possible to make in 1917 tend to confirm growers' statements that plants from seed sown at the end of April or beginning of May suffer much less than those from seed sown in February. (3) Liming must not be neglected. As well as improving the tilth, lime acts by liberating reserves of nitrogen and potash, and its effect on the Parsnip is seen in the improved quality of the crop both in size of roots and decrease in the amount of decay. (4) A dressing of salt has been found very effective by some growers. On heavy soils 5 cwt. per acre should be applied, and on light soils up to 10 cwt. per acre may be used. The salt may act by liberating a certain amount of potash from the soil, and one of the most marked effects of potash is to retard maturation and to enable the plant to continue its vegetative growth. It is possible that this effect may extend to the phellogen (rind-producing layer) and consequently render it less liable to rup-

ture. For the same reason potash manures should prove beneficial. (5) A proper rotation should be adopted: Parsnips should never be grown for two years in succession on the same land.

CLUB ROOT OF BRASSICAS.

As gardeners are aware, club root causes serious damage to Cabbages, Savoys, Cauliflowers, Broccoli, Turnips, and other plants of the Cabbage tribe, but all are not conversant with the best means of combating the disease.

Now that many seedling Brassicas are being planted, the following particulars may be useful. In its later stages the disease is easily recognised; for when the diseased plants which have failed to grow and mature properly are pulled up the roots are seen to be swollen in large, irregular lumps. The seriousness of the disease is due to the fact that in its early stages it often escapes notice, therefore, if proper precautions are to be taken against club root it is important that the roots of all seedling plants should be examined at the time of transplantation. Any plants on the roots of which there are suspicious-looking swellings should be rejected. If such plants are used, not only will they fail to mature, they will also infect the soil and cause the disease to appear in other plants of the Cabbage tribe planted in the same or following year.

It is particularly important that a careful inspection should be made of the roots of the seedlings before they are planted. It is no less important to make sure that the soil bed in which the plants of the Cabbage tribe are raised is free from the disease. The commonest way in which the disease is spread is by transplanting Brassicas from infected soil into fresh, unaffected soil. The parasite which causes the disease is invisible to the naked eye, and is capable of lying like a dormant seed in the soil and of resuming its activity later and penetrating into the delicate hairs on the roots of young Cabbage plants.

The second point which should receive attention is that the disease is almost invariably present in soil, especially poor soil of an acid nature; therefore, before planting Cabbages or similar crops the soil should be tested. This is easily done by means of blue litmus paper, a supply of which may be purchased from any chemist for 2d. If a leaf of the blue litmus paper pressed against a moist sample of the soil to be tested and left for half an hour becomes red, the soil is acid, and should be limed or chalked thoroughly before Cabbage crops are planted in it. For light soils powdered chalk or limestone should be used at the rate of from 28 to 56 lbs. to the square rod. It may be dug in at any time. If the soil is a stiff clay, freshly slacked lime should be used at the rate of 28 lbs. to the square rod. It should be bought as quicklime (unslacked lime), spread in heaps on the soil, covered with a little earth, and allowed to remain for about a fortnight, and then spread evenly and dug in. The lime should not be allowed to come into contact with the roots of living plants, nor should it be dug in so as to come in contact with manure.

If the disease is known to be present in the soil, no plants of the Cabbage tribe should be planted in the ground until the soil has been treated with quicklime. This treatment is best carried out in the autumn, and in any case two or three weeks must elapse between the time of applying the lime and planting the crop. Care should be taken when using the quicklime to protect the face, hands, and clothes from the burning action of the lime. The lime should be spread on a still day and at the rate of 1 lb. to the square yard. The quicklime should be dug in immediately after it has been applied.

Where small numbers of seedlings are to be raised and the soil of the garden or allotment is known to be infected, the seed should be sown in soil sterilised by heating or by treatment with quicklime.

The minute spores of the fungus are often carried on the roots of diseased plants to the compost heap; they infect the soil of the heap and are carried back with the compost to the vegetable plot. Again, diseased plants are often left lying on the ground and the spores which they contain are carried back into the soil.

Should one or two plants show by their failure to thrive that there is something wrong with them, they should be pulled up, the whole plant with the soil attached to the root burnt, and the place from which the root was pulled should be treated at once with lime.

PRIMULA ELATIOR × JULIAE.

In addition to considerable variation in habit and colour of flowers, the charming Caucasian Primula Juliae has proved a prolific parent for the purpose of hybridisation. At the meeting of the Royal Horticultural Society on March 26

[*Photograph by W. Irving*

FIG. 96. PRIMULA ELATIOR × JULIAE: FLOWERS MAUVE.

1918, a hybrid of P. Juliae and the common Primrose was shown by Messrs. Waterer, Sons and Crisp, and obtained an Award of Merit under the name of P. Crispii. It had the vigour of the latter with more reniform, smoother leaves, and the fine rosy purple flowers of the former parent. On March 26 last a Primula was shown at the R.H.S. meeting under the name of Jewel, and obtained an Award of Merit. It was stated to be a cross between P. Juliae and a blue Primrose. Having compared the two plants I can find no difference between them.

At Kew this spring seedlings appeared amongst a colony of the Oxlip (P. elatior). There were two different forms; both had the reniform leaves of Juliae on long petioles, and they were slightly hairy, but while the flowers of one were mauve in colour, the other was yellow, as in the Oxlip. Thus in the plant illustrated in fig. 96 the influence of P. Juliae is seen in the leaves and the colour of the flowers, while in the other its influence is shown in the leaves only. The two hybrids were growing closely together, surrounded by Oxlips, while the pollen parent was growing a few yards away. The more vigorous of the two is the form with the mauve flowers, but the yellow hybrid has a more refined appearance. W. I.

LETTERS FROM SOLDIER-GARDENERS.

MELONS IN MACEDONIA.

We have long looked on Greece as the natural home of the Currant and other kinds of fruits, but for my part, after the war, I shall also be inclined to regard it as the home of the Melon, for never before have I seen this fruit grown to such perfection as I have seen it out here.

After an experience extending over three summers in this country, I cannot help marvelling at the ease with which the very best types of Melons are grown in the open fields, with little or nothing in the shape of cultivation; in districts sufficiently removed from the operations of war the Greek still pursues the (more or less) even tenor of his way, and is chiefly occupied during the summer months in what we should term his "market garden," where his chief products are Melons and Tomatos, the former being his most lucrative crop.

Such minor details as deep digging or manuring trouble him not at all; in fact, more often than not, an old wooden plough and a clumsy implement not unlike a manure rake, furnish his sole implements for soil tillage, and the ground is left almost in the same condition as an English gardener would leave his vegetable plot in late autumn.

The seed, which is saved from year to year, germinates with surprising rapidity in the open ground from late April onwards, and the plants produce excellent fruit during August and September. No pinching or stopping is practised,

the plants being allowed to ramble at will, while artificial pollination is a thing undreamt of; yet, on an average, each plant will produce at least half-a dozen splendid fruits, many of them as much as eight or even ten pounds in weight, of perfect shape, colour, and flavour, and more often than not, evenly netted all over.

Where there is anything in the nature of a water supply the Melon beds are usually made on a lower level than its source, and ditches are cut into which the water is diverted at intervals; but in the majority of cases water is not available, and no effort at irrigation is made, with the result that in an average season the plants will go practically the whole course of their existence without watering.

Yet, strangely enough, red spider and kindred pests are unknown, and, as I have said, the fruit finishes to perfection.

The natives seem to have only the very vaguest notion of the commercial value of the fruit, for they seldom ask more than two drachmae (1s. 3d.) for the most perfect specimens, and even then a Greek never expects to get more than half the price he asks for any of his wares, and with that he is well content. I have often bought for a shilling, or even less, Melons which I should only too well have liked the opportunity of staging at Vincent Square or at the Shrewsbury Exhibition, knowing that they would have small difficulty in holding their own in every respect against our best hot-house productions at home. *J. E. Palmer, late of Tilston Lodge Gardens, Tarporley, Cheshire.*

ORCHID NOTES AND GLEANINGS.

SOPHRO-LAELIO-CATTLEYA MRS. RICKARDS.

R. WINDSOR RICKARDS, Esq., Usk Priory, Monmouthshire, sends a two-flowered inflorescence of a brightly-coloured hybrid between Cattleya Dowiana aurea and Sophro-Laelio-Cattleya insignis (C. Enid × S.-L. Psyche). C. Mossiae and C. Warscewiczii in C. Enid give the fine form and rich colour; the latter is a bright rose with a slight violet shade. The lip is dark purplish-crimson, with yellow lines from the base. The influence of Cattleya Dowiana aurea can be traced, although the cyanic colour of the other parents has suppressed its yellow in the same manner as the scarlet of S. grandiflora and L. cinnabarina in S.-L. Psyche has been obliterated. In a good light, however, a certain glow can be perceived in the colour of the sepals and petals of the hybrid, derived, doubtless, from its red ancestors.

HYBRID ORCHIDS.

(Continued from April 13, p. 155.)

Hybrid.	Parentage.	Exhibitor.
Brasso-Cattleya Beaumont	B.-C. Cliftonii × C. Empress Frederick	Dr. Miguel Lacroze.
Brasso-Cattleya Henri Constantin	B.-C. Marguerite Fournier × C. labiata	Mons. A. Marcoz.
Brasso-Cattleya Princess Mary	B. C. Digbyano Schröderae × C. chocoensis alba	Flory and Black.
Brasso-Laelia Jester	L. Jongheana × B.-L. Jessopii	Pantia Ralli, Esq.
Brasso-Laelio-Cattleya Ivernia	B.-C. Thorntonii L.-C. Canhamiana Lady Wigan	S. Gratrix, Esq.
Cattleya Golden King var. Peter	Hardyana × Venus	Flory and Black.
Cattleya Mendoza	Fabia × Empress Frederick	Dr. M. Lacroze.
Cymbidium insigniculum	insigne × Lowianum	G. Hamilton Smith, Esq.
Laelio-Cattleya Marco	L.-C. Mona × C. Schröderae	Stuart Low and Co.
Laelio-Cattleya Sextus	L.-C. Feronia × C. Schröderae	Stuart Low and Co.
Laelio Cattleya West Point Rex	L.-C. bletchleyensis × C. Empress Frederick	S. Gratrix, Esq.
Odontioda Colinge	Odm. crispum Ethel × Oda Coronation	C. J. Phillips, Esq.
Odontioda Ernestii	Odm. Wilckeanum × Oda Charlesworthii	E. R. Ashton, Esq.
Odontioda Mira	Oda. Bradshawiae × Odm. miriam	F. Smith, Esq.
Odontioglossum Adonis	Jasper × Mars	Armstrong and Brown.
Odontioglossum Amazon	crispum × miriam	Armstrong and Brown.
Odontioglossum Cittianiara	sceptrum × Fascinator	Dr. M. Lacroze.
Odontioglossum Colret	ardentissimum × Thais	C. J. Phillips, Esq.
Odontioglossum Cyra	nitidum × Lambeauianum	C. J. Phillips, Esq.
Odontioglossum crispicello	crispum × Othello	C. J. Lucas, Esq.
Odontioglossum Cumbe	crispum xanthotes × Philippianum	C. J. Phillips, Esq.
Odontioglossum Diricinum	Dyce × eximium Warnham Court var.	C. J. Lucas, Esq.
Odontioglossum Dorcen	eximium × Empress of India	Charlesworth and Co.
Odontioglossum General Foch	Armstrongiae × Colossus	Armstrong and Brown.
Odontioglossum Marjorie	illustrissimum × Pescatorei Veitchii	Charlesworth and Co.
Odontioglossum Miguelito	Dora × Doris magnificum	Dr. M. Lacroze.
Sophro-Laelio-Cattleya Mrs. Rickards	S.-L.-C. insignis × C. Dowiana aurea	R. W. Rickards, Esq.

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

HARICOT BEANS.—Seed of the different kinds of Haricot Beans should be sown at once in rows made 2 feet apart in the case of dwarf varieties and 4 or 5 feet apart for climbing sorts. Choose fairly rich ground, and an open situation. None of the pods should be gathered green, but all allowed to ripen seeds for winter use. The Dutch Brown variety distributed by the Royal Horticultural Society last season has proved excellent for the purpose, and is a most valuable food for winter use.

FRENCH BEANS.—Such varieties of French Beans as Canadian Wonder may be sown now in quantity. Where possible, grow the plants in isolated rows and sow the seeds thinly. Mulch the plants and keep them well supplied with water in dry weather. Remove the lights from cold frames in which French Beans are growing, and see that the plants do not suffer from want of water at the roots.

TURNIPS.—Very early Turnips on warm borders have not done well, so that those grown in frames have been doubly useful. After this date roots from these early sowings will become tough and hot in flavour, therefore make fresh small sowings fortnightly in freely manured, well-worked ground, to ensure a rapid growth. On north and east borders, as Turnips are of the greatest value during the late summer and autumn. The drills should not be less than 18 inches apart, and the plants should be thinned to 8 inches apart in the rows. Red Globe is a useful variety for summer sowing. Early Snowball and Golden Ball are also excellent sorts for small gardens. Let the roots be well supplied with water in dry weather, and keep the ground between the rows stirred with the hoe. Both the Turnip flea and slugs may be warded off by occasional dustings of soot and lime or wood ash.

ENDIVE.—There is not much demand for Endive when Lettuce is plentiful and properly blanched. It is not, therefore, advisable to sow much seed of this salad yet, but a sowing of a good selection of Moss Curled, Green Curled, and Batavian kinds should be made in rows 12 inches apart for the curled varieties, thinning them later to the same distance in the rows, allowing 15 to 18 inches for the broad leaved varieties. Make further sowings once a fortnight, where a continual supply is required. Keep the plants well watered and the ground frequently stirred between the rows to favour quick growth and to keep down weeds.

RADISHES.—The best Radishes are those that grow quickly, and, seeing that they soon become hot and stringy, small fresh sowings should be made every fortnight on a well-manured border that has been dug long enough for the soil to have become thoroughly pulverised. The most reliance may now be placed on the red and white Turnip-rooted kinds. Seed may be sown broadcast or in drills. Where the Turnip flea is troublesome, the seedlings should be dusted occasionally with soot and lime while the dew is on them.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

BEGONIA GLOIRE DE LORRAINE.—Continue to propagate this Begonia if cuttings are available. Late-struck plants are useful as table decorations during the winter. The earliest batch of plants should be ready for their final potting, and pots 7 inches in diameter are a suitable size. A compost formed of good fibrous loam, peat, leaf-mould, manure from a spent Mushroom-bed, and coarse sand is suitable. Grow the plants in a moist, warm house, and shade them during the hottest part of the day. Admit air through the top ventilators in the forenoons, more or less, according to the weather, but close the house early in the afternoon after thoroughly spraying the plants with rain-water. When the plants are well rooted the occasional use of diluted soot water will produce deep green colour in the foliage.

EUPHORBIA PULCHERRIMA (POINSETTIA).—Re-pot cuttings of Poinsettia which have been rooted before they become pot-bound, and keep them growing freely in a moist, warm house. If very tall plants are desired, they should be grown in a warm house with plenty of atmospheric moisture all through the summer. Grow the dwarfer plants in a cooler and drier atmosphere. Another batch of cuttings may be rooted now to obtain plants for flowering in small pots. Insert the cuttings without delay after severing them from the old plants and plunge them in a hotbed in a propagating frame. Keep them from flagging by spraying them regularly with rain-water and shading them during hot weather until roots have formed.

CALCEOLARIA.—A sowing of Calceolaria should be made now, and, if necessary, another in a month's time. Sow the seed in shallow pans containing a mixture of loam, leaf-mould, and sand. It is important to make the soil firm, or it is apt to dry too quickly. The seed of Calceolaria is very small, and must be handled carefully, or it may be sown very irregularly. It is a good plan to mix such very small seeds as those of Calceolaria with sand which has been passed through a hair sieve; it is easier then to distribute it evenly over the surface of the seed pan. The soil should be soaked with water before the seed is inserted. The seed will germinate freely in a cool temperature. Cover the pans with glass and shade the latter till the seedlings are through the soil. The Calceolaria requires cool treatment through all stages of its growth.

THE ORCHID HOUSES

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate

ODONTOGLOSSUM HOUSE.—At the present time and during the summer months the inmates of the Odontoglossum house should be kept as cool as possible. Endeavour to maintain a temperature in the daytime of 60° to 65°, and 55° to 60° at night. The higher temperature should be maintained whenever the outside atmosphere stands at about 50°, but when colder, the lower one is preferable. Fire-heat should not be employed during the day, but on damp, chilly nights the hot-water pipes should be slightly warmed. This should be counterbalanced by opening the bottom ventilators a little more; the fresh air will prevent the flowers from becoming injured through condensed moisture settling on them. The house should be damped thoroughly three or four times on bright days, and the plants judiciously shaded and watered. Those not in flower should be sprayed overhead twice at intervals on sunny days, sufficiently early in the afternoon for the leaves to become dry before night. Admit air freely through the bottom ventilators on favourable occasions.

EAST INDIAN HOUSE.—Now that the amount of daylight has increased, the majority of the

plants in the East Indian House are growing and rooting freely, and the night temperature maintained by fire-heat should be advanced a few degrees—i.e., to 65° to 70° at night, and during the day when the weather is warm and bright, several degrees higher, with sun-heat. It matters little how far the temperature may rise by means of sun-heat, provided there is sufficient moisture and ventilation. Many of the occupants of this division, including such plants as Angraecums, Aerides and Saccolabiums, are developing numerous aerial roots, and the plants should be afforded only sufficient water to keep the surface layer of Sphagnum-moss in a healthy, growing condition. Some of the plants are sending forth their flower-spikes; weakly specimens that have lost many of their bottom leaves should not be allowed to flower until they have regained more vigour. Many of the dwarf-growing Angraecums, such as A. Ellisii, A. citratum, A. Leonis, A. Kotschyi, A. arcuatum, A. hyaloides, and others of this class, are starting into growth, and any necessary re-potting should receive attention. Shallow Orchid pans form the most suitable receptacles, and a compost consisting of equal parts of A 1 fibre, Sphagnum-moss, cut up rather short, leaf soil, and crushed crocks should be used, with a surfacing of clean, picked heads of Sphagnum moss. Grow the plants in the coolest and shadiest part of the house.

THE HARDY FRUIT GARDEN

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

FIGS.—Syringe Fig trees planted in borders daily in hot weather; they should be syringed at least once a day, but on two occasions will do no harm if the trees are old and woody. Regulate the shoots, taking care to preserve the coming growths, but pinch side-shoots at the fourth or fifth leaf to cause the embryo fruits to swell. It will scarcely be necessary to disbud the trees. I would rather pinch the shoots to two leaves than do this. The trees must not suffer from drought in the slightest degree. Figs are often planted on sloping borders, where rain does not penetrate at the foot of the wall in a sufficient amount for the plant's requirements. In such cases it would be advisable to apply a mulch to the border. Endeavour to get the fruits to swell early so as to have them ripe by the end of July or early in August. If movable glass copings are in use it will be advisable to take them off until the first fruits are swelling for ripening. Younger trees, or those that have been root-pruned, should be encouraged to grow rather than to mature a full crop of fruit this season. Regulate the growths of newly-planted trees, and encourage shoots to develop from their bases to have well furnished plants. Control the shoots by stopping as may be necessary. Take care that no other crop shades the trees. Figs do best when grown on borders by themselves, as in the case of outside Vine borders.

VINES.—Where hardy Vines are growing in the best possible positions their growth should now be well advanced. Stop the laterals at the second joint beyond the bunch, and do not allow more than one bunch to remain on each shoot. Disbud the Vines sufficiently to permit freedom of growth without overcrowding. Allow the leaders to extend where there is room, and if a promising young shoot appears from the base do not stop it until it has grown some 5 feet or more. Tie the lateral shoots on all the spurs to prevent them being damaged by high winds. Newly-planted Vines should be encouraged to grow freely, and should not be cropped this season. Syringe and water them freely in order to have well-established plants.

APRICOTS.—Apricot trees are growing freely, and the breast wood will need to be pinched soon. Do this, wherever possible, when the shoots are quite young. Where the fruits have set freely they may be thinned and the surplus ones utilised for preserving green. Examine the borders for watering. At this season plenty of water is essential to the rapid growth of both fruit and foliage.

CHERRIES ON WALLS.—Wall Cherries are growing rapidly, and the fruit is swelling freely; no other fruit swells so quickly as the Cherry. Do not let the trees suffer for want of water. If the crop is a heavy one weak liquid manure should be given the roots. Stop all breast wood by pinching it at an early stage of development.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to MRS. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

MELONS.—When the fruits show signs of changing colour, the supply of water at the roots need only be sufficient to prevent the foliage from flagging. If the plants are grown in pots with the stems rising a little above the rims, or planted on ridges of soil, there will be no difficulty in regulating the supply of moisture. The atmosphere, also, should be kept drier. A fairly high temperature with a free circulation of air should be maintained to produce Melons of good flavour. Water may be withheld entirely as the fruits commence ripening, and the amount of ventilation increased. The cracking of the stalks and strong aroma of the fruits are sure signs of the Melons being ripe enough for cutting; they should be cut with a piece of stalk adhering and placed in a warm, dry fruit-room for use as required. The young fruits on successional plants swell very rapidly at this season. The roots should be given warm liquid manure diluted to a suitable strength, concentrated fertilisers, or top-dressings of rich, turfy loam mixed with bone-meal. Feeding should not be done to excess, or the fruits will be coarse and bellied. Pinch and tie the laterals, allowing them plenty of room, for the production of good Melons depends largely on having plants furnished with healthy foliage. Ventilate the house freely during bright weather, but close the ventilators sufficiently early in the day to raise the temperature of the house to rise to 90° after syringing the foliage freely. Let the fruits be supported in the early stages with Melon nets or pieces of garden netting. Later plants will send out plenty of laterals that will bear female flowers, if the main shoots are pinched just before they reach the top of the trellis. The flowers should be exposed to the sun and pollinated daily. When the fruits show signs of swelling, pinch the shoots two leaves beyond them. Make a final sowing at once of varieties suitable for autumn fruiting.

CUCUMBERS.—A few Cucumber plants will produce an enormous amount of fruits over a lengthened period, provided they are not overcropped at any time. Keep the shoots pinched, and remove all unnecessary growths and foliage to permit of space for training in new shoots as the old growths become exhausted. The roots will respond to liberal top-dressings of loam and rotten manure, with occasional doses of diluted liquid manure or light sprinklings of concentrated fertilisers. The syringe should be used freely to keep the plants healthy and free from red spider. Syringe not only the plants themselves but the paths, bare spaces, and under the stages. Cucumbers need liberal supplies of clear water at the roots.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

BANKSIAN ROSES.—As soon as the flowers of Banksian Roses are over the plants should be pruned. In our case this is restricted largely to thinning out old wood to give space for younger growth, which is allowed to droop freely in long shoots. Unfortunately, the winter of 1917 and last winter damaged these Roses severely, one specimen having been killed outright, and the survivors need cutting hard back in order to induce fresh growth to break from near the ground. Fortunately, Roses respond well to hard pruning, which is a ready means of rejuvenating worn-out specimens, as well as those which, like the Banksias referred to, have suffered from frost.

SCARLET RUNNERS.—When Runner Beans are ready, those intended for planting in the flower garden may be planted out. Our plants have been twice stopped, and they will be planted at 3 feet apart, a space which they will rapidly cover, after which they will need to be trimmed occasionally to prevent them from growing out of bounds, or encroaching on other plants or grass verges. I am planting 100 yards to flower, and during the earlier part of their existence the early pods will be removed, but the later ones will be left to mature to produce Beans for eating. Press the soil firmly about the balls of the plants when they are planted.

TENDER BEDDING PLANTS.—Such bedding plants as Lobelia, Ageratum, Mesembryanthemum (Ice Plant), Verbenas, and Pelargoniums (Geraniums) may be planted now, to be followed by tuberous-rooted Begonias. Besides reducing the number of flower beds here, several have been filled with hardy annuals, and instead of using tall plants, which require stakes, the remainder are being furnished largely with Pelargoniums and Begonias. As already noted, summer flowers appreciate a dressing of superphosphate, which is raked into the soil previous to planting. All will be soaked with water as they are planted, and the surface soil, when moderately dry, will be hoed and levelled round the plants. The single watering will constitute the whole water to be supplied. Because of a scarcity of labour, what "bedding" remains to be done will be largely sandwiched between other pressing jobs. None of the many vases here have been filled since 1914, more on account of the time that would have been occupied in watering than any objection to furnish them with plants.

THE APIARY.

By CHLORIS

TRANSFERRING BEES FROM SKEPS. Some times it is possible to secure a skep of bees cheaply, but if one is desirous to keep bees in the most up-to-date manner the difficulty arises how to get them out of the skep. They can be got out by a method termed "driving" which is both simple and safe. Give the bees a puff of smoke through the entrance and wait a few moments, for they will at once commence to gorge themselves with honey, which they always do when frightened. (The honey thus taken is necessary should the bees be deprived of their combs, so that they may build new ones with the wax made from the honey they take at such a time, and the honey-sac being distended makes them desirous not to use their stings. Thus they can be handled with little fear of being stung). Give them a second puff and overturn the skep, and at once puff smoke across the combs to drive the bees down. Take the upturned skep and place it in a bucket, above the skep fix a second empty one to receive the bees from that below, seeing that the contact between the skeps is perfect on one side at the ends of the comb, and tap the sides of the full one with the palms of the hands until all the bees have ascended. This operation should be performed about 7 p.m., after the bees have ceased to be on the wing, or many will be lost. The bees can then be put into a bar-framed hive fitted with sheets of foundation and wired in. To prevent loss of brood, those combs containing brood should be cut out and tied into the frames by two tapes, taking care to cut the top quite straight so that it may be brought up to the top tightly, and the bees will seal them, otherwise, should a space be left they will use it as a passageway. Those who are afraid to undertake driving may place the skep above the frames, and when the queen is below, place a sheet of queen excluder zinc over the frames. As the brood above hatches, those cells will be filled with honey, and thus the skep will become a super. Take care to pack the skep warmly and leave no open space above the frames.

SUPERING.—The great advantage of the modern hive is that the surplus honey can be stored in clean combs in which no brood has been raised, thus making the food more hygienic than is possible in the skep system. Anything suitable in size may be used, but the best supers are those containing sections or shallow frames, the former for comb honey and the latter for extracting. Undoubtedly the best flavoured honey is obtained from sections, as the delicate aroma cannot evaporate, being securely sealed in by the cappings. When glasses are used the inside surface should be slightly smeared with wax, but they are easily broken and not readily handled, nor is such comb honey readily saleable.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, JUNE 8—
Kew Guild ann. meet., Kew Gardens, at 6 p.m.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 59.1

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, May 30, 10 a.m.: Bar. 30.4, temp. 66.5°. Weather: Bright sunshine.

The Progress of Food Production.

We cannot deny ourselves a special measure of satisfaction in learning from the report of Mr. Prothero's speech at Bedford on May 25 that the great programme of increased food-production laid down some eighteen months ago is in course of fulfilment. This journal from the earliest months of the war has urged the importance of increasing the food raised in these Islands, and there can be no doubt that the agricultural and horticultural Press generally has had a considerable influence in bringing about the remarkable results which, as we understand from the President's speech, have been achieved: results which may be summed up in Mr. Prothero's statement that to-day "the acreage under Wheat, Barley and Oats is the highest ever recorded in the history of our agriculture." The part which our food supplies will play in determining the issue of the war is so momentous that this present satisfactory situation must be viewed with cautious optimism. In building up large quantities of food supplies in this country, by no means the only question to be considered is the feeding of our armies and the civilian population. These large reserves of home-grown food—if they materialise—represent a great financial asset, and no one requires to be a professional financier to realise the supreme importance of such an asset. The war necessitates on the one hand a large increase in our imports, and a no less large reduction in our exports. Freight charges have risen to a high figure, existing tonnage is insufficient for the sea-carriage of essential supplies, and therefore, even though the submarine be less menacing, the need for maintaining and increasing yet further home food production is paramount. The present danger lies in this, that those who are not fully informed of the importance of food production may be inclined to drain the land yet further of the man-power essential to production, and in particular to deprive intensive cultivation of the skilled labour without which it cannot make its proper contribution to the food supply. There are signs that those who determine who shall be taken for the Army and who shall be left on the land have not a thorough appreciation of the importance and essential needs of intensive cultivation. We trust that these signs are local, and not general, and that those whose duty it is to obtain the man-power so urgently required for the Army will not make the serious mistake of ignoring or belittling the claims of market gardeners, professional gardeners, and fruit-growers, to equal consideration with those who cultivate extensively. It only requires, on the one hand, a scrutiny of the amount of vegetable food produced by intensive cultivation, and, on the other, a knowledge of the great curtailment of imports of fruit and vegetables, for any person of average intelligence to realise that in the interests of the nation special consideration should be given to those engaged in intensive cultivation. This is true of market gardening and of fruit-growing. In the case of the latter, the situation demands that everything that is possible should be done to encourage the largest possible production of home-grown hardy fruit. By common consent the present is likely to prove a bad fruit season; so bad that it is difficult to see how the needs of the Army and of the civil population are to be met. Let no man think that fruit is a luxury. The luxuries of peace may become necessities in war, and this is the manifest case with fruit. The health of the Army depends no less on jam than on meat and bread, and on this fact the medical authorities are emphatic. Unless the fruit-grower is not only not discouraged, but actually encouraged, there is a serious risk of "jam yesterday and jam to-morrow, but never jam to-day." Unfortunately, people with a flimsy sense of humour and a lack of understanding find it difficult to take the jam pot seriously. We assure them that it must be taken seriously—that the Ministry of Food can inform them how seriously it must be taken, and that unless those who grow our hardy fruits receive the largest measure of consideration compatible with the military situation, the indispensable supplies cannot be forthcoming.

Finally, let no one think because of the truly remarkable results which have been achieved that yet further efforts in food-production are not wanted. They are, for those efforts are the surest of all insurances against war-risks.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Committees of the Royal Horticultural Society will be on the 18th inst., in the Drill Hall, Buckingham Gate, Westminster.

THE FRUIT TREES OF BELGIUM AND FRANCE.—A suggestion has been made* by Mrs. SHERWIN RAY to the effect that a fund should be started in the United States for the purpose of replanting the devastated orchards of France and Belgium. We would recommend that if the suggestion is adopted, those organising the fund should act in co-operation with the committee established by the Royal Horticultural Society for a like purpose. It would be an admirable means of bringing together the horticulturists of the Allied countries in an enduring work of reconstruction.

* *The National Nurseryman*, U.S.A., May, 1918.

THE GARDENERS' COMPANY.—Alderman Sir CHARLES WAKEFIELD has been elected Master of the Gardeners' Company. The Wardens are Mr. P. TEOFANI and Mr. FRANCIS AGAR.

FRESH-WATER ALGAE.—Mr. W. DENISON ROEBUCK has presented to the University of Leeds a collection of microscopic slides and a library of books upon the subject of Fresh-water Algae, as the nucleus of a specialist library and collection of Algae in general. These were the property of the late Mr WILLIAM BARWELL TURNER. The value of the gift is enhanced by the fact that many of the books are illustrated by coloured drawings done by Mr. TURNER, who was a talented natural history draughtsman. The collections will be known as the "Barwell Turner Memorial," and will be available for the use of students of algological science.

MR. J. R. JACKSON.—Mr. J. R. JACKSON, late Curator of the museums at Kew, attained his eightieth year on May 26. He is the oldest surviving member of the Kew staff, as to service, though Mr. J. G. BAKER is his senior by five years. Many members of the botanical and horticultural fraternities will have pleasant memories of his active life, and congratulate him on completing his eightieth year.

THE EFFECT OF LIGHT IN HEALING TREE WOUNDS.—Experiments have been made in the Dutch East Indies on four year-old rubber trees of equal dimensions, to prove the influence of light with regard to the healing of wounds of the bark. From each tree a strip of bark and cambium, measuring 1 by 5 centimetres, was cut at a height of 1.5 metre from the ground, and the wound was covered, excepting a small opening at the bottom, with pieces of blue, green, yellow, red, and colourless glass. The best results were obtained with the blue and colourless glass; yellow glass gave the worst results, all the wounds under this becoming mouldy. It appeared also that wounds from which the rubber scraps had been removed healed more slowly than those in which scraps had been left, while the latter healed less rapidly than wounds covered with colourless glass, thus indicating that it is desirable to cover wounds on the trees as a healing measure.

AROIDS FOR CROPPING.—A correspondent in the *Philippine Agriculturist and Forester*, Vol. VI., Nos 2 and 3, records some tests made with Yautias and Gabis. This is a continuation of the work begun by QUISUMBING and OCFEMIA. These tests confirm the previous results that the Yautias (Xanthosoma sp. "Dasé Ala" Sinh.) are the most profitable as field crops. In fact, the Gabis and Dasheens (Colocasia sp. "Gahala" varieties) are shown to yield so poorly that they cannot be cultivated successfully under field conditions. To be a commercial success the yield should be at least 625 lbs. of rootstock per acre. The Colocasia sp. at their very best do not give more than 450 lbs. per acre.

JAPANESE LARCH.—A note* by Sir HUGH R. BEEVOR on Japanese Larch at Hargham, Norfolk, points out that this tree is continuing to prove resistant to canker. Of a wood of Japanese Larch 8 feet apart, scarcely ten trees show sign of the disease.

AMERICAN PLANTS.—Part LIII. of *Contributions from the Gray Herbarium of Harvard University* is entirely devoted to the description and synonymy of American plants, and chiefly to North American, by J. F. MACBRIDE and S. F. BLAKE. The discussion and application of almost absolute priority in names occupies considerable space, but it will be long before

* *Quarterly Journal of Forestry*, 2, XII., April, 1918.

the alterations find a place in horticultural literature, and still longer before they are accepted and used by gardeners. Not that many cultivated plants are concerned in this part of the publication. The Liliaceous genus Zigadenus and a long series of Chenopodiaceae come under this kind of critical revision. Fremontodendron mexicanum is reduced to Fremontia, and rightly, no doubt. Lomatium replaces Cogswellia—in spite of the familiar Lomatium and Cogswellia not long since was revived for Peucedanum! Other "new combinations" are made in favour of dates partly, and partly on modified generic limitations. Among new plants from Venezuela and Curaçao may be mentioned Hecatostemon, a new genus of Flacourtiaceae; Jacquinia mucronulata, Plumeria cochleata, and Dianthera pleurolaryux. Schismocarpus is a new genus allied to Mentzelia. It was discovered in the Department of Pochutla, Oaxaca, Mexico, where it bears the name Camote de llama. "Camote is a name for the Sweet Potato, and evidently refers to the thick tuberous [illegible] of the plant."

HEATHER BURNING. The advantages of systematic Heather burning are manifest both with respect to grazing and sporting value. As an example the case of a Scotch hill farm may be cited. By systematic burning over ten years the production of wool and lambs was increased by 25 per cent. and the bag of grouse nearly doubled. If it is to prove successful Heather-burning must be carried out according to plans laid well in advance, and should be spread over a period of years. But whatever plan is adopted its execution must be modified according to circumstances, for it is important that the burning should only be attempted during suitable weather, and that, although generally the oldest parts should be marked down for burning, any patches attacked by the Heather beetle should be burned at the earliest possible moment. Patches selected for burning should not be too large—10 acres or so is a good area, and the strips burned should alternate with unburned strips. Imperfect burning does harm to the grass and therefore burning should not be attempted unless the Heather is sufficiently dry. In England autumn burning has been practised with success, but in Scotland it has proved unsuccessful. April is the month recommended in that country. Burning should be done against the wind, as the rate and extent are more under control of the fires and beaters, and the burning being slower than it would be if done with the wind, produces better results.*

WAR ITEMS.—Mr. P. C. M. VEITCH, Exeter, has been officially notified that his son, Major LEONARD VEITCH, was killed in action in France on May 21. Major VEITCH, who was 31 years of age, had been on active service since the first day of the war, and had, with the exception of his brief periods of leave, and a short time spent in England whilst passing through his O.C.'s course, been on the Western Front since Christmas Eve, 1914. Educated at Exeter School, he afterwards went to Germany and Holland to complete his studies in horticulture and landscape gardening. Major VEITCH was mentioned in despatches for good work, and had the reputation of being a fearless and resourceful officer. The greatest sympathy will be extended to Mr. P. C. M. VEITCH, who has himself only recently left hospital, where he has been under treatment for a severe accident.

Staff-Captain JAS. O'BRIEN, M.C., elder son of Mr. JAMES O'BRIEN, has been appointed Staff Captain of an infantry brigade. Captain O'BRIEN and his brother went in the ranks of the Artists' Rifles to Flanders in October, 1914, and have been on active service abroad ever since. We are glad to learn that Lieut. JOHN O'BRIEN, King's African Rifles, has recovered from his wound of April 30.

* Leaflet No. 42, Board of Agriculture for Scotland.

THE ALPINE GARDEN.

ANEMONE ALLENII

ANEMONE ALLENII was raised by the late Mr. James Allen, of Shepton Mallet. The plant is rather taller than A. Robinsoniana, and has a little touch more of purple in its colouring; it has been described as of a more opal shade than A. Robinsoniana, and that is probably as good a description as it is possible to arrive at. There are, I believe, two forms of the plant in cultivation, the one is more compact and floriferous than the other. My plants came from Mr. Allen direct, and there can, therefore, be no dubiety as to the correctness of my stock. The variety cannot be said to be superior to A. Robinsoniana, but it is a distinct Windflower and useful in collections. *S. Arnott.*

THE DOUBLE CRIMSON POMPADOUR PRIMROSE.

THE true Pompadour Primrose has been exhibited by Messrs. R. Gill and Sons at R.H.S. fortnightly meetings this spring. It is a plant of comparative rarity, and difficulty attends its cultivation generally in southern gardens unless exceptional means are adopted. To such an extent is this true that I was once told it was almost impossible to grow the plant south of London. Even with ordinary cultivation, and in the places beloved of the Primrose, the variety is not particularly attractive. In the instances referred to the flowers were hardly of average size, and finer flowering specimens are seen occasionally among the Primula exhibits at the National Auricula and Primula Society's exhibition in London. Realising the difficulty of cultivating this beautiful flower by ordinary methods, I have more than once resorted to growing it in a frame of the crudest description, the sides being of packing cases fastened to each other, with stakes driven into the ground for supports. Of these enough to accommodate two or perhaps three frame lights, 4 feet 6 inches wide by 6 feet long, were arranged. A low-lying or cool spot was chosen for the frame, with distant tree shade. The plants were grown in a layer, one foot deep, of loam and leaf mould mixed with a third part of old cowdung; the cowding was used for its cooling nature rather than for high manurial value. Planted in this mixture and divided annually or biennially as necessary, the lights shaded if other shade was not at hand, this favourite old flower was a considerable success. The plants were watered overhead when they were in full growth; soot water or weak liquid manure was also applied overhead without stint, a treatment in which they revelled. With growth completed and the summer heat passed, the lights were removed. To treat a hardy Primrose in this manner in these days of labour scarcity would appear almost an extravagance, yet it is one of the very few ways of making this particular variety a complete success in the warmer counties of England. *E. H. Jenkins.*

(See Awards of the Floral Committee, p. 250.)

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

COLOUR IN FRUITS AND VEGETABLES.—For some time past I have been studying the question of colour in fruits and vegetables, and trying to ascertain the reason why colour should be so highly appreciated in certain kinds, and its absence in others. For instance, most or all of the yellow fleshed Apples have the best flavour and quality, and are generally appreciated. Are there any white-fleshed Apples of high quality? Stewed Pears are most appreciated when they assume a more or less decided amber tint. On the contrary, coloured Potatos are chiefly cultivated and sold by nurserymen for exhibition purposes, and market growers seldom plant them. King Edward VII. is an exception, being the most popular coloured Potato at the present time. White-fleshed varieties are most appreciated, yet the yellow-fleshed tubers are mostly of excellent quality and flavour. Certain varieties, with decidedly yellow flesh, are known as Connoisseur Potatos, yet their cultivators are not numerous, although their quality is considered high. When I was a boy our people grew about a dozen varieties, most of them coloured and yellow-fleshed. The most highly appreciated had dark violet-purple skins and decidedly yellow flesh, and the only reason why they were not extensively cultivated was their susceptibility to late blight. There is more dry matter in yellow Turnips than in white ones, and still more in Swedes, with a greater sugar content, yet the cook in many private establishments must have white Turnips. Red-fleshed Beet is most highly appreciated, yet the yellow-fleshed Sugar Beet contains far more sugar. Red-fleshed Carrots, in my experience, are of better quality than yellow ones, and the latter have long been eliminated from gardens. In this instance colour rightly takes precedence. Yellow Tomatos are of good quality, and appreciated by those who know them, yet the market grower will have nothing to do with them. White-seeded Runner, Dwarf, and Climbing French Beans are by most people considered the proper and only varieties that should be grown for drying. The Brown Dutch kind seems destined to become popular for drying for winter use, and the flavour is considered excellent by those who have tried it. The Dwarf Bean, Negro Long Pod, is being grown this year for drying, and in this case the seed is black. *J. F.*

COOKING HARICOT BEANS (see p. 211).—Many will cordially agree with Messrs. Barr and Sons that these Beans would be in "general use the year round if the modes of preparing and cooking were better understood." The point in my mind is whether that desirable consummation is likely to be effected by boiling them from 1½ to 2 hours, as stated. I think not. The complete cooking of the Haricot Bean is not a question of the degree of hardness of the water only, but very much also a question of the extent to which the Beans themselves have been dried, and, as in the case of all shop-purchased Haricots, the "extent" is unknown. The soaking in cold water an essential in the case—is not likely to be overdone. The twelve hours stated should be the minimum, twice that number being generally favoured in my household. Those intended for the mid-day meal are brought to the boil at breakfast time (8 a.m.), and kept gently simmering until required for dishing up. In this way the Beans become quite tender, constituting a most delightful dish, and minus the acrobatic agility they display in restaurants and like places when only half cooked. *E. Jenkins.*

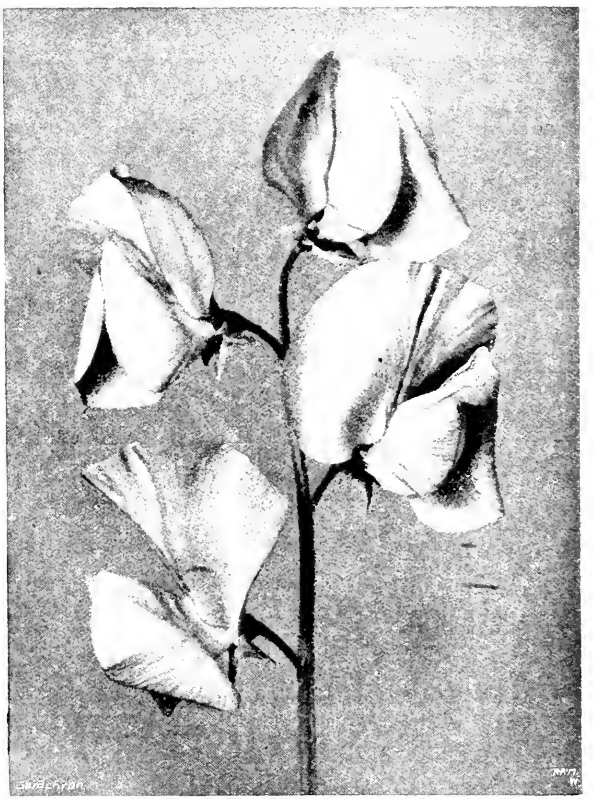

FIG. 93.—SWEET PEA MRS. J. W. BISHOP: COLOUR SOFT CERISE. (See Awards by the Floral Committee.)

CLIMBING HARICOT BEANS (see p. 210).—I advise those who intend to grow Climbing Haricot Beans to consider the following points before they make the attempt: Is the summer long enough for the Beans to mature, and is there ground to spare for a chance crop; also will Bean-sticks be available, and their cost? We may rely on Potatos, Onions, Carrots and Leeks as certain crops, but success with Climbing Haricot Beans is doubtful. Last year I grew four rows, each 40 yards long, of these Beans. I tried some of the young pods cooked green, but they were tasteless, and before a good crop of Beans had formed in the pods early frosts appeared. I do not mean to imply that the crop was a failure everywhere, but it is not worth growing as a crop for winter use by allotment holders and others who have only a little ground. *C. Davis, Holy Wells Park Gardens, Ipswich.*

SOCIETIES.

ROYAL HORTICULTURAL.

MAY 28.—The fortnightly meeting on Tuesday last, held in the Drill Hall, Buckingham Gate, Westminster, attracted a considerable number of Fellows, and there was a good exhibition. There were several fine exhibits of Orchids, and the Orchid Committee recommended one Award of Merit and one Preliminary Commendation to novelties.

There was a full attendance of the Floral Committee, and this body recommended seven Awards of Merit to novelties, and awarded seven medals to groups. Amongst the latter were a collection of Irises shown by Messrs. R. WALLACE AND CO.; Sweet Peas from Messrs. ALEX. DICKSON AND SONS, Marks Tey Nurseries; a group of well-flowered Azaleas shown by Mr. L. R. RUSSELL; and Messrs. H. B. MAY AND SONS' usual group of fine indoor Ferns, interspersed with batches of flowering plants. One or two nurserymen showed flowering branches of decorative trees and shrubs, and Messrs. G. REUTHE and R. TUCKER AND SONS exhibited Alpines and hardy flowers. Mr. G. W. MILLER had a very comprehensive exhibit of spring garden flowers, including a giant, purple Brompton Stock, for which he was awarded a Cultural Commendation. Mr. JAMES DOUGLAS' exhibit of border Carnations contained blooms of the highest excellence, and he gained awards for two new varieties. A selection of the best Perpetual-flowering Carnations was contributed by Messrs. STUART LOW AND CO. Mr. F. GIFFORD, Hornchurch, exhibited a fine batch of Paeonia officinalis lobata, a goblet-shaped flower of coral-red colour, shading to cerise at the edge. Mr. A. DAWKINS brought two new Calceolarias which attracted considerable attention; one (Buttercup) received an Award of Merit, the other, named Canary Bird, was equally floriferous, but of a less rich shade of yellow. Messrs. HERBERT CHAPMAN, LTD., staged a number of hybrid Irises, the result of intercrossing the so-called Dutch varieties.

Messrs. DOBBIE AND CO. contributed three new varieties of Sweet Pea, of which the finest was named Ivorine, a large, pale cream variety, buff tinted.

The Fruit and Vegetable Committee found very little to consider, and the only award made in this section was a Provisional Award of Merit to Apple Pershore Pippin, which resembles a russety fruit of Winter Peach.

At the 3 o'clock meeting of the Fellows an address on "Practical Meteorology" was delivered by Mr. W. M. ROBERTSON.

Floral Committee.

Present: Messrs. H. B. May (Chairman), John Green, George Paul, R. C. Notcutt, S. Morris, R. W. Wallace, W. J. Bean, G. Harrow, E. A. Bowles, G. Reuthe, J. Heal, C. R. Fielder, T. W. Barr, W. Howe, J. Hudson, J. Jennings, A. Turner, C. Dixon, J. Dickson, C. E. Shea, E. F. Hazelton, W. P. Thomson, and E. H. Jenkins.

AWARDS OF MERIT.

Calceolaria Buttercup (see fig. 97).—A hybrid from the Herbaceous Calceolaria crossed with a hardy, shrubby, yellow variety. The colour is exceedingly rich, and the plant, as will be seen from the illustration, is very floriferous. Speci-

mens grow to a height of about 18 inches, and make excellent subjects for conservatory and greenhouse decoration; they are also stated to be suitable for summer bedding. The variety is said to come true from seed. Shown by Mr. ALFRED DAWKINS.

Syringa Swegincowii superba. — This new Chinese species has a laxer spike than the common Lilac, and is, in consequence, more decorative and more graceful. The petals are white, and the tube is pale lilac-rose both sides. The petioles and young stems are tinted with rose, the leaves themselves being smaller than in the common Syringa. Shown by Mr. C. TURNER.

Carnations the Grey Douglas and Surrey Clove.—The former is a large, striking bloom of slaty-grey colour, the latter a rich shade of crimson and very fragrant. Both are border varieties. Shown by Mr. JAMES DOUGLAS.

Sweet Pea Mrs J. W. Bishop (see fig. 96 — The colour of this beautiful new variety is soft cerise, a shade popular with florists. It is likely to become a valuable market variety. Shown by Messrs. ALEX. DICKSON AND SONS.

Lupins Delight and May Princess. These two varieties were selected by the Committee for award amongst a number contributed by Mr G. R. DOWNER, Chichester. The flowers of Delight are dull carmine-lake *Rep. des Couleurs* 106, Tone 2), and the keel petals are stained with purple. May Princess is dark violet-purple, almost blue in parts.

GROUPS

The following medals were awarded for collections:—

Silver-gilt Banksian Medal to Messrs. ALEX DICKSON AND SONS for Sweet Peas.

Silver Flora Medals to Messrs. H. B. MAY AND SONS, for Ferns and greenhouse flowering plants; Mr G. W. MILLER, for hardy flowers; Messrs R. WALLACE AND CO., for Irises of the Germanica section; Mr L. R. RUSSELL, for Azaleas.

Silver Banksian Medals to Messrs. J. CHEAL AND SONS, for flowering shrubs and trees, including Rhododendrons, also Star Dahlias; Messrs PAUL AND SON, for flowering trees and shrubs; Messrs. PIPERS, for flowering shrubs; Mr G. REUTHE, for Alpines; and Mr F. GIFFORD, for Paeonia officinalis lobata.

Bronze Banksian Medals to Messrs R. TOLKEP AND SONS, for Alpines; Messrs. H. CHAPMAN LTD., for Irises; and Messrs. STUART LOW AND CO., for Perpetual-flowering Carnations.

Orchid Committee.

Present, Sir Harry J. Veitch (in the chair), Messrs Jas. O'Brien (hon. secretary), William Bolton, W. H. White, R. A. Rolfe, R. G. Thwaites, Pantia Ralli, Fred K. Sander, J. E. Shill, J. Charlesworth, W. H. Hatcher, W. J. Kaye, W. Vear Cobb, and R. Brooman White.

AWARDS.

AWARD OF MERIT

Odontioda sanderiana Beauty of Ashtead from PANTIA RALLI, Esq., Ashtead Park, Surrey (Orchid grower Mr W. H. White). A beautiful home-raised form obtained by crossing O. crispum Rossendale and O. c. Empress of India. The finely grown plant bore a spike of seven large, well formed flowers; the inner two-thirds of the segments are heavily blotched with dark purplish red, the broad white margins effectively displaying the colour. The lip is white, with dark red blotches in front of the yellow crest.

PRELIMINARY COMMENDATION

Odontioda Juno, from Messrs. ARMSTRONG AND BROWN.—A beautiful new hybrid raised from Odontoglossum eximilius and Odontioda Coronation, the seedling having much of the large size and fine substance of the Odontoglossum parent but adhering more closely to the Odontioda parent in colour, than which it is both darker and brighter. The white surface of the segments is, for the greater part, covered with large, concentric, ruby red blotches, the margin having a freckled rose coloured band. The lip is white with ruby red blotches.

GROUPS.

Messrs. ARMSTRONG AND BROWN were awarded a Silver gilt Flora Medal for an excellent group of finely-grown hybrid Orchids, including several new Odontoglossums and Odontiodas, among which were noted Odontioda Madeline Orchidhurst variety (Odm. crispum × Oda. Charlesworthii), equal in size to an Odontoglossum, and bearing a well-formed, yellowish-white flower which has many large chestnut red blotches almost covering the surface; the lip has a distinct chestnut red blotch; Odontioda Monte Rosa, of unrecorded parentage, and an improvement on the original Odontioda Vuylstekeae; Odontoglossum Aireworth Orchidhurst variety differing from the ordinary forms in having a clear white ground and distinct claret blotches and Odm. Alcibiades (crispum × Colossus).

Messrs. CHARLESWORTH AND CO. were awarded a Silver gilt Flora Medal for a fine group of Miltonias, mostly raised by them, and including many handsome forms of M. vexillaria, such as M. v. Lycth and varieties of M. Charlesworthii with bright rose flowers having a deep ruby crimson mask on the lip. With them were arranged many handsome blotched Odontoglossums and several of the clear white xanthotes forms of O. eximium and O. crispum, together with brilliantly coloured Odontiodas.

PANTIA RALLI, Esq., exhibited Odontoglossum crispum Masterpiece, a seedling plant bearing a spike of thirteen clear white flowers.

H. T. PITT, Esq., Rosslyn, Stamford Hill, gr. Mr Thurgood, showed a strong specimen of the rare Bulbophyllum Balfourianum, with a short cluster of four singularly formed flowers, the ground is cream white spotted with claret red, the inner parts of the segments claret red. In colour, substance and odour the species calls to mind some of the Stapelias. The species was illustrated in *Gard. Chron.*, July 24, 1915, p. 53.

WALTER CORBE, Esq., Normanhurst, Ristol (gr. Mr C. J. Salter), showed cut spikes of Dendrobium Lyonii, Odontioda Bradshawiæ, Cobb's variety, and a handsomely blotched Odontoglossum.

Messrs J. AND A. MCBEAN, Cooksbridge, showed a fine specimen of Dendrobium Sanderæ.

Messrs. STUART LOW AND CO., Jarvisbrook, Sussex, were awarded a Silver Flora Medal for an effective group of Cattleyas and Laelio-Cattleyas, Odontiodas and Odontoglossums. The finest of the first named was Odontoglossum Phipsoni of rare colouring, the plant bearing a spike of [illegible] flowers.

Sir JEREMIAH COLMAN, Bart. (Gatton Park, — Mr C. [illegible]), submitted four flowers of their Odontoglossums for the remarks of the Committee as to their improvement. The largest, shown "The flowers handsomely marked, was referred to O. Landsborough, a most probable extreme form of O. crispum. The other two are of Orchid had been purchased in the Continent as O. crispum variety, were nominated as being forms of O. eximium.

Narcissus and Tulip Committee.

Present: Miss E. A. Bowles (in the chair), Miss Willmott, Messrs. Herbert Smith, J. T. Bennett-Poe, P. R. Barr, Herbert Chapman and Charles H. Curtis (hon. secretary).

Usually at this date there are good exhibits of late-flowering Tulips, but on this occasion there was not a single Tulip in the hall, this was the final meeting of the Committee for the season.

Fruit and Vegetable Committee.

Present: Messrs. J. Cheal (in the chair), W. Poupart, P. D. Tuckett, A. Bullock, A. J. Allan, F. Jordan, J. Allgrove, A. W. Metcalfe, E. A. Bunyard, G. P. Berry, W. H. Divers, W. Wilks, and Ed. Hartiss.

CROPS AND STOCK ON THE HOME FARM.

RHINANTHUS CRISTA-GALLI (YELLOW RATTLE).

This British parasite is an obnoxious pest in some grass fields. It is rarely seen where the grass grows luxuriantly, which shows that the presence of the weed is mainly due to poverty of soil. The best remedy is to encourage the free growth of the grass by the use of manure. Poor pastures never pay; if they cannot be improved they should be ploughed and cropped for several years before they are again sown with grass seed. Agricultural salt sown over the turf in the spring is said to prevent the growth of Yellow Rattle, and certainly it improves the quality of the grass, especially if a dressing of basic slag is applied in the following autumn at the rate of 5 cwt. per acre.

THE REARING OF TURKEYS.

The American Mammoth Bronze Turkey meets all requirements of hardiness, size, quality of flesh, and of egg production. A hot, dry summer suits turkeys best, continuous wet and cold causing chills, diarrhœa, and roup. Although turkeys are easily hatched in incubators, I prefer to put the eggs under hens, especially during cold or wet weather. Ten eggs are sufficient for one hen to cover properly, and twenty-eight days is the normal period of incubation. When the poults hatch, remove the shells, but do not attempt to hasten hatching by premature removal, for if the chicks are made to bleed they are almost sure to die. Allow them to remain under the hens until they are thoroughly dry; they do not need food for the first twenty-four hours. Place a boarded floor coop with a detachable bottom on grass. Cover the floor with a dry, clean bag for warmth for two days, frequently changing the bag. The first feed should be hard-boiled eggs, soaked chicken meal, and chopped green Onions. Green Chives are also good food. The chicks should be fed four times daily, a little at a time.

For the first fortnight they should be confined to a wire run in front of the coop on grass, changing the site daily. A space sufficient for the coop should be mown closely, as long grass is liable to give cramp and roup. As the poults increase in size the coop should be moved to a new site twice daily. Gradually increase the supply of Onion food, and add fine grit. Should the bird have diarrhœa, cease to give eggs for a few days, and add finely powdered chalk to the mixture.

PIGS.

Now is a good time to buy store pigs of eight weeks old to run through the summer for killing in the autumn. During the winter warmth makes a considerable difference to the manner in which pigs progress. A considerable quantity of green food can be obtained from the garden. Sugar Beet is a valuable food, and keeps fresh a long time when kept from the sun and drying winds. The roots should be steamed or boiled, and mixed with meal and milk.

All who purpose purchasing store pigs would be well advised to obtain a first cross from a pure-breed. *E. Molyneux.*

Obituary.

S. J. ALLEN. We learn from the pages of our contemporary, the *National Nurseryman*, U.S.A., of the death, in his 77th year, of Mr. S. J. Allen, the inventor and manufacturer of the Planet Junior farm and garden implements. We suppose that it is no exaggeration to say that these implements are used wherever gardening is practised, and certainly the gardening community is under a large and lasting obligation to the inventor of the Planet Junior implements. Like the inventor of the drill, Mr. Allen was originally a farmer, and the experience of hand hoeing inspired his inventive faculty. His first implements were made by the village blacksmith, and Allen soon discovered that these labour-saving tools were in demand among his neighbours. He was thus led to establish a manufacturing plant in Philadelphia. During the past 50 years the factory has grown until now it covers many acres.

J. S. GRAINGER. We regret to record the death of Mr J. S. Grainger at his residence, 17, Park Hill, Clapham, at the age of 77, after a long illness. The deceased was well known and esteemed by the seed trade, especially in the North of England and Scotland. He was for many years in the employ of Messrs. Peter Lawson and Sons, and was manager of their branch in London until they gave up the tenancy. He then joined the firm of Messrs. Jacob Wetzell and Sons as traveller, and remained with them for many years until the business was given up. He afterwards travelled for Messrs. Nutting and Sons, Ltd., with whom he had been 12 years at the time of his death.

MARKETS.

COVENT GARDEN, May 29.

Plants in Pots, &c. Average Wholesale Prices.

			Smilax, per bun. of 6 trails ...	4 0–	4 6

REMARKS.—There is almost a famine of cheap flowers, the supply being exceptionally short. The crops of double White Narcissus finished during last week. At present there is only a limited supply of White Stock and double White Pyrethrum. Coloured varieties of the latter, both double and single, are an increasing supply daily. A few White Lilies are being offered, and, like all white flowers, are selling well. Such pieces as Lilium longiflorum and Richardias (Arums) are again reduced in number, and prices are higher. Cornflowers, Gypsophila (white and pink), Iceland Poppies, Sweet Peas, and Chrysanthemum maxima are more plentiful. Carnations are sufficient for the demand, but little can be said about Roses, the quality being very poor.

Mint, per doz. bun.	4 0–	6 0			
Mushrooms, per lb.	1 6–	2 0			

REMARKS.—Indoor fruits are now more plentiful, including Black Hamburgh and Muscat Grapes, Peaches, Nectarines, Figs, Melons, and Strawberries. Southampton and Cornish Strawberries are on offer. Continental Asparagus is over, but English Asparagus is fairly abundant. Egyptian Onions are exceptionally dear, as much as 75s. being asked per bag. Oranges and Lemons are scarce and expensive. Supplies of English and Channel Islands Tomatos are increasing daily. Beans and Peas are scarcer. Mushrooms show a slight increase in supply, but Cucumbers and Vegetable Marrows are not so plentiful as usual at this season of the year. *E. H. E., Covent Garden Market, May 29, 1918.*

GARDENING APPOINTMENTS.

MR J. SMITH has left the Tower Nursery, South Benfleet, as Gardener at the Surrey County Asylum, Netherne.

MR F. S. SELMES has left the firm of MESSRS. WHITE AND SELMES, North Kensington, as Foreman to MR W. LEIGHTON GRAHAM'S Nursery, Purley.

MR D. ARTHUR has left Gosford Gardens to the late MR. DAVIES, Gerrards Cross, Bucks, to Kirkandrightshire, as Gardener to C. L. GALBRAITH, Esq., Ferrigies House, Kirkandbrightshire.

ANSWERS TO CORRESPONDENTS.

BEES IN AN ELM TREE. *H. C.* We fear you will be unsuccessful in obtaining the bees from the tree. You may be able to purchase a stock of swarm from the following firms: Messrs. E. H. Taylor, Welwyn, Hertfordshire; Mr. W. Woodley, Beedon, Newbury, Berkshire; Messrs. James Lee and Son, Ltd., George Street, Uxbridge, Middlesex.

BERMUDA ONIONS: *Seedsman.* The Bermuda Onions are distinct from those we grow. They are only suitable for a hot climate, where they give good returns. They are not a success in this country.

CHICOREI DE BRUXELLES. *J. P.* Brussels or Witloof Chicory is a strain of the Magdeburg Chicory, and is grown for use as salad from December till the end of February. The seeds, which are obtainable from seedsmen, should be sown in May or very early in June in rich ground, in drills made 12 to 15 inches apart. They germinate freely, and the seedbed should be kept constantly damp. When the plants are large enough, they should be thinned to 1 foot apart. A light dressing of sulphate of ammonia applied late in July is very beneficial to the crop. Towards the end of August the largest leaves should be removed. Late in October the first batch of roots may be lifted carefully for forcing, discarding the smaller crowns. All the leaves should be broken off close to the collar by hand, and the roots left exposed to the weather for eight or ten days. It is preferable in England to force the roots in deep frames or in a shed. They should be placed in rows made 6 inches apart, and a space of 2 inches allowed between the plants in the rows. The roots should be covered with a layer 10 to 12 inches deep of fine soil. The only attention the plants need afterwards is protection from frost. The crop is ready for cutting as soon as the crowns break through the surface. The soil should then be removed and the head cut with a heel from the collar. The second batch for forcing should be lifted at the end of November, and the last a month later. Some growers market the heads loose in boxes, each holding 6 lbs.; others bunch them in 1 lb. bundles.

GALLS ON OAK: *Miss Pile.* The gall is that known as the "Woolly Gall," formed by the insect Andricus ramuli.

INSECTS: *A. Turner.* The insects are larvae of Caratid, or ground beetles; they are beneficial in gardens.

NAMES OF PLANTS: *W. and S.* 1, Pyrus Aria (White Beam); 2, Crataegus coccinea.—*J. H.* 1, Syringa Emodii; 2, Staphylea colchica.—*T. D.* Sansevieria zeylanica.—*W. B.* Tradescantia virginica.—*F. G. S.* Claytonia sibirica.—*F. F.* Carex riparia, the largest British sedge.

PEARS, PEACHES, AND MELONS: *Pomus.* Pinch the shoots of the Pear tree at the sixth or seventh leaf, and do not allow subsequent shoots to develop. Blistered leaves on Peach trees should be removed and destroyed, and the trees syringed on two or three evenings with water containing 2 oz. of soft soap to the gallon. Melons are best grown without shading so long as the temperature does not exceed 95°. Early ventilation on bright days is necessary; if the ventilators are opened after the house becomes very hot the plants will flag.

POTATOS OR POTATOES: *G. W.* The practice of omitting the "e" after "o" in such words as Potatos and Tomatos has existed in the pages of the *Gardeners' Chronicle* for many years, on the ground that, though unusual, it is correct, and is merely an anticipation of a usage which will become more and more general. Already the penultimate "e" has been dropped in many similar words.

VINES IN AN UNHEATED VINERY: *Pomus.* An unheated vinery facing east requires ventilation at the top of the roof as early as 8 a.m. at the present time, and 5 o'clock at midsummer. If it faces south, two hours later will do, and when it cannot be attended to thus early it is safest to leave the ventilators open a little all night. Mildew and red spider can be eradicated, in the absence of a sulphur vaporiser, by dusting flowers of sulphur on the leaves after damping them, and keeping the temperature for a considerable time up to 85° by sunheat, or the sulphur may be mixed with soapy water and applied in the form of spray, by placing a finger against the nozzle of a syringe. Mealy bug may be kept in check during the growing season by syringing with Campbell's Necrosoap, 1 oz. to the gallon of soft water, and Vines can be thoroughly cleared of this and all other insect pests by painting two or three times during the dormant season without removing the bark, with the same compound, at a strength of 4 ozs. to the gallon. All sub laterals excepting the one at the axil of the first leaf should be removed.

WEED IN LILY POND: *J. W. M.* Ascertain the amount of water contained in the pond by multiplying together the average length, breadth, and depth in feet, and multiplying the result by 6¼, the approximate number of gallons in a cubic foot. One pound of copper sulphate should be used to every 100,000 gallons of water. Break the material small, and enclose it in a bag of loose texture. Tie the bag behind a boat, and draw it along in the water in parallel paths about 10 to 20 feet apart. The copper sulphate will not injure the Lilies, nor any fish that may be in the water, if care be taken not to allow the bag to remain stationary in one part of the pond. If the weed is very thick it will be well to clear the surface of the water as much as possible before applying the copper sulphate.

NOTES FROM KEW.—VI.*

BRIGHT sunshine and unusual warmth from May 15 to 22 shortened the flowering period of a large number of plants which are usually in bloom for several weeks. Rhododendrons and Azaleas bloomed and withered with extraordinary rapidity, as also did Lilacs, Chestnuts, Hawthorns, and many other showy flowered trees and shrubs. They had a brief season, and if all goes well such plants generally should seed freely this year.

Irises at Kew have ceased to behave well, though there was a time when the Iris garden was a great feature in May. Then disease appeared, and, on the advice of the plant doctor, they were subjected to treatment, but they have never recovered. The disease, known as Iris rot, is said to be due to bacteria. Masses stated that it was very prevalent in this country and on the Continent, whole beds being sometimes destroyed by it. The leaves wilt, turn yellow, and die, and the rhizomes rot. Removing and burning the worst and transplanting the others in fresh soil proved to be hard labour in vain, as also did the application of specifics. We have struggled to overcome this disease, but nothing short of destroying the whole collection and starting afresh in another part of the garden will set matters right. This is a large order, but it will have to be done when the war is over, unless the cultivation of such plants is to be abandoned at Kew. According to our Museum Guide, Iris florentina, I. pallida, and I. germanica are largely cultivated for their rhizomes in Continental countries to supply the Orris root of commerce. The roots are dug up in August, trimmed, peeled, dried in the sun, and then sorted into different qualities. I believe our Iris troubles began when transplanting in August was first practised. It is, in my belief, so utterly opposed to nature to dig up rhizomatous Irises when they are not only in full leaf, but actively growing, that we are asking for trouble by doing it. Bulbous Irises are different. They stand such treatment as well as Daffodils, Tulips, and many other bulbous plants do. Cottagers never make this mistake, and it is in their gardens that one may see these Irises as happy as Rhubarb and Horseradish.

"Then why did you dig yours up in August?" someone will ask. Because gardeners, like other folk, are too ready to be guided by faddists and fashion. Someone says it is the right thing to do, and we believe them and practise it.

The rock garden, under the influence of sun and warmth, assisted by a frequent use of the hose-pipe, has come on with a rush, and for the last fortnight or so it has been at its zenith of interest and attractiveness. Many Primulas lasted only a short time. P. Cockburniana is still a patch of flame colour, almost too vivid to be looked at; I prefer the hybrids from it, Unique and Lissadel. Under the shade of a Yew tree, P. helodoxa is delightful. Clearly it is a shade-lover; probably all Primulas are, where the sun has any power. I should call helodoxa the Chinese form of imperialis, and if anything a better garden plant. It must be looked after for seeds, the plant being short-lived. In my last "Notes," P. davurica is mentioned among the several flowering in the rock garden. It should have been darialica (see fig. 99). The two names are less alike than the two plants they stand for, both being forms of P. farinosa: davurica, according to Professor Balfour, occurring in Siberia, North Mongolia, and North America, and darialica in the Caucasus. P. farinosa is the Bird's-eye Primrose of our bogs and meadows, scotica being a purple form of it. Being the commonest and widest-spread of all Primulas, and therefore very variable, its forms are a source of worry to botanists, scores of species, so called, having been made from its variations. It is a comfort that they all have more or less the same value in horticulture as the type, and that the name farinosa may well stand for them all.

A true blue flowered Meconopsis horridula, and a colony of M. aculeata showing a variety of colours, are happy under the shade of tall Hollies, and M. paniculata, with yellowish flowers, near by, is also good. Cypripedium spectabile has made itself at home on a dry slope, upsetting the belief that it will not thrive except in swampy conditions. Orchis foliosa, O. maculata, and O. latifolia are almost weeds in the Kew rockery, and the hybrids from them are happy there also. Two of the most persistent weeds are Erinus alpinus and a black Viola—V. tricolor nigra. Being harmless and pretty, they are allowed free range. Oxalis adenophylla and O. enneaphylla are represented by large healthy patches, now smothered with flowers. Aster subcoeruleus, A. alpinus, and its variety Garibaldi, are two of the most effective plants. Celmisia spectabilis has 16 perfect flowers on it, and is probably what Mr. George Paul called it the other day—the best plant of this New Zealand species in England. As for Saxifrages, they are at top form, including S. longifolia, with a fox-tail-like spike of sparkling white flowers in a setting of Dianthus caesius, which clothes one side of what we call the peak, the highest point in the rock garden. There are numerous large cushions of Dianthus of sorts, alpinus (quite 2 yards across), dependens, neglectus, deltoides, and several hybrids.

The best show of Alpine Pinks I have ever seen was at Glasnevin. These plants are apt to burn and go off in patches at Kew, the fate of too many Alpines in this garden. Anemone obtusiloba has become established in a partially shaded position. Half a dozen seedlings of it from Kew-saved seeds gave only one blue-flowered plant like the parent, the other five being white. Pentstemon scouticlorus and P. heterophyllus are good rockery plants at Kew, and so is Eriogonum subalpinum.

Weldenia candida is pushing up through the soil, and is evidently quite hardy at Kew. The bog garden is crowded with fat plants of Rodgersia, Iris Kaempferi, Lysichiton, and a thriving clump of Ranunculus Lyallii. Mr. Elwes is probably right (p. 211) in his view that the white Lysichiton is a distinct species from the yellow one. A figure of the Kew plant of the former, which this year has grown strongly and flowered well by the side of a rock pool in the Temperate House, has been prepared for the *Bot. Mag.*, and a photograph of it is reproduced in fig. 100. The spathe of L. camtschatcense (see *Gard. Chron.*, April 6, 1918, fig. 67) is ovate in outline, but in the white one it is almost cordate. The latter came, I believe, originally from the Petrograd Botanic Gardens as L. c. alba.

Paeonies are receiving special attention at Kew from Dr. Stapf, who hopes to be able to set their names in order. There are, in my belief, too many species. The best in flower now are romanica, lobata, peregrina, officinalis, Emodii, Broteri, anomala, and Veitchii, which are all known in gardens. If I wished to plant two of the best species for effect, I would prefer the red lobata, which Mr. F. Gifford showed in quantity at the R.H.S. meeting on the 28th ult., and the white Emodii. Paeonies grow well under trees, even Elms, and they look very much at home among Ferns, as may be seen in the wild garden at Kew, where plants of the old double crimson Paeony have thriven for years under the shade of Elms and among Male Ferns.

Before leaving the outside garden, I must mention Magnolia parviflora and M. Watsonii, both of which have flowered freely this year. The Wistarias have also flowered well, and they are quite gay still. The Azalea garden has been as much a Mecca for visitors as ever, and the Rhododendron Dell has still many grand bushes of the later flowering sorts. Mr. George Paul informs me that he has crossed a number of good garden Rhododendrons with the Chinese R. decorum, a late flowerer, in the hope that a race of summer-flowering

* Previous articles appeared in the issues of January 19, February 9, March 9, April 6, and May 18.

hybrids may be thus obtained. I am not particularly in love with decorum, which is only a slight variant from Fortunei, and has not the odour that characterises the Japanese plant. This year the difference in the time of flowering between Fortunei and decorum was only about a fortnight.

Calceolarias are now a strong feature in the Conservatory (No. 4) too strong, perhaps, the excuse being that Mr. Coutts has been crossing them and has raised some showy mongrels, those from C. cana and what he calls the carpet-bag Calceolarias being the most pleasing. They are heavily spotted and free-flowering. C. Clibranii is good, and so is C. Allardii, a three-pli hybrid raised at the John Innes Horticultural Institution by Mr. Allard from herbacea, angustifolia, and plantaginea. As a pot plant for the greenhouse and for summer bedding I think Allardii will find much favour; a photograph of one of the Kew plants is reproduced in fig. 101. Years ago Mr. John Jeffreys, Oxford, crossed the "carpet-baggers" with, I think, amplexicaulis, and obtained a race showing great variety of colour and pleasing habit which was named Jeffreyi. The plants were tried for bedding at Kew and were a great success.

Leptospermum Chapmanii has been admitted to the front rank among showy greenhouse plants, and it will, I believe, become a rival to Cape Heaths and Epacrises. Mackaya bella is flowering freely this year, and Elaeocarpus cyaneus is good in No. 4 House. Haemanthus Katherinae, the Irish strain, as we call it, is grandly in flower in the Mexican House, where, planted in the borders here and there, it has made itself at home. Magnolia macrophylla is in flower in the Himalayan House. Two giant Bromeliads, namely, Tillandsia Glaziovii and T. gigantea, are flowering in the Victoria House, where Nymphaea gigantea is another great attraction to visitors. The Nepenthes are at present under a cloud, thanks to a visitation from painters, who are worse than the ten plagues when they get inside a plant house. In the Orchid houses Sobralias, Schomburgkia tibicinus, Vanda Charlesworthii, Renanthera Imschootiana and Angraecum Scottianum are the best things in flower.

I am able to report progress in the vegetable department. The Potatos planted on the palace lawn are growing well, thanks, I believe, to dressing the soil with sewage sludge from Mortlake. The Onions in the Palm House Terrace garden look promising, and there is no fly on them, so far. A crop of Spring Cabbage has been marketed, and the nursery crops of Turnips, Cauliflowers, and other vegetables are thriving. The flower-beds are now showing seedlings of various food plants, some of which ought to be interesting as well as good to eat. W. W.

FIG. 99.—PRIMULA DARIALICA: FLOWERS ROSE-COLOURED.

(See p. 233.)

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM CRISPUM LEEANUM

MR. RICHARD ASHWORTH, Ashlands, Newchurch, Manchester, sends us a flower of a remarkable and distinct form of Odontoglossum with the following remarks: "I am sending a flower cut from a seedling Odontoglossum crispum flowering for the first time, named O. crispum Leeanum. The parents are O. crispum Black Prince, bought from the Continent 17 or 18 years ago, and O. crispum General Roberts, which is a finely blotched flower. The Black Prince crosses give the very darkest colour I have ever seen, and this dark colour is carried forward to all the descendants. If you hold the flower up to the sunlight and look through it the shade is a lovely dark maroon."

The flower, which is of good shape, has dark maroon sepals with clear white margin and some white showing at the base. The petals have a white ground, but the greater part of their surface bears large maroon blotches. The lip, which is slightly fimbriated, is white with a yellow crest, in front of which is one large and several smaller maroon blotches. It is a showy variety, and the darkest we have seen.

LAELIO-CATTLEYA EXCELSIOR THE DELL VARIETY.

WE have received a flower of this handsome cross between L.-C. Canhamiana Rex and C. Mendelii, from a plant raised in The Dell Gardens, Englefield Green. The defect in L.-C. Canhamiana (L. purpurata × C. Mossiae) is in the folding back of the petals. By the cross with C. Mendelii the defect has been effaced, the hybrid having flatly-arranged petals some 7 inches long and 3 inches wide. The substance of the flower, and the size and width of the lip, make it a great advance on L.-C. Canhamiana. The sepals and petals are pure white, and the front of the lip Tyrian-red. The original form was first shown by Messrs. E. H. Davidson and Co., Twyford, at the Yorkshire Gala, 1913, and recorded in the *Gardeners' Chronicle*, June 21, 1913, p. 430.

ODONTOGLOSSUM CRISPUM EASTERN PEARL.

A FLOWER of a pure white form of Odontoglossum crispum taken from an imported plant is sent by R. G. Thwaites, Esq., Chessington, Streatham. In the purity of its white the new plant resembles O. crispum xanthotes, which was first imported and flowered in 1894, and of which varieties have since appeared, but it is of much more perfect shape, and the distinguishing occasional lemon-yellow spotting seen in all forms of xanthotes is absent. Although not of the largest size the variety Eastern Pearl is one of the most perfect and attractive of the typical O. crispum varieties.

The sepals are ovate, the petals almost circular in outline, rather broader than long, and slightly fringed. The lip, which is broader than usual in the species and slightly fringed, has a pale yellow shade in front of the crest, the whole of the flower with that exception being snow-white.

NOTICES OF BOOKS.

THE ALLOTMENT MONTH BY MONTH.

THIS is the title of one of the latest pamphlets on vegetable cultivation in war-time. It is written by Mr. R. H. Crockford, and edited by Mr. Clarence Elliott, of Stevenage, who contributes the preface. Some of the more expensive vegetables are omitted—such, for instance, as Asparagus—as being unsuitable for allotment cultivators; and in regard to the more popular sorts, it is hardly to be expected that anything very fresh could be said about them. At the same time the letterpress is evidently written by a practised hand. Allotment holders and all growers of little experience, who have not already furnished themselves with some of the very numerous pamphlets which have been issued during the past two years, will find Mr. Crockford's contribution to the subject of very great value. It contains nearly thirty pages, and is published at 7d. net.

PROTECTING STRAWBERRIES.

VARIOUS means are adopted to preserve ripe Strawberries from dirt and grit, and the question is not so much which mode is the best, as which is the most convenient for the particular garden. The practice of surfacing the ground with fresh, strawy manure not only serves the purpose of protecting the plants from frost, but also that of giving nourishment to the roots. After a time the litter is washed perfectly clean and the straw becomes bleached, leaving a close, clean, strawy surface in the spring for the fruit to rest on and from which it can be gathered in a clean, sweet state.

But this method is not always successful. In wet soils the manure may cause the crowns to decay, and in gardens where slugs are unusually numerous the winter's surfacing affords them harbourage, and they emerge from their haunts in the spring and destroy the fruit. However, where the practice has been adopted little more is now needed, but where no litter has been applied measures must be taken to thwart it, or a thunder shower of half an hour's duration may spoil the work of a season.

Whatever means are adopted for keeping the fruit clean, it is important that the material be applied at once. To allow the surface of the ground until the berries are approaching ripeness is an error which is too often committed. The heavy trusses cannot be lifted to have straw put under them without injuring the stems, the result of which is a check to the berries' swelling. The rough handling of the trusses is a prime source of small fruit, as the stems are as susceptible to injury as is the haulm of Peas. Protection should be given when the stems are erect, and before they are flattened to the ground by the weight of the fruit.

Some growers use twiggy sprays to hold the fruit above the foliage. The plan is a good one, but all have not the twigs, and a capital substitute is to insert three or four sticks around each plant, and run a strand of twine around each root, or, if the roots are close, a strand along each side of the rows will suffice. This method is simple and effectual. Others use wire supports, these being simply a half-circle of wire on three legs. The supports are forced into the ground, two half circles to each plant—and form a capital supporting cradle. The wires are easily made, and will last for years. The common practice of littering with clean straw is always effectual. The straw should be cut in 1-inch lengths; it is then easily placed around the plants from baskets, half the amount of straw will do, and it is more quickly applied than when long. Short straw is, moreover, the best preservative of the fruit from slugs. Slugs cannot travel freely on the round, loose particles of straw, which form an ever moving surface. The very best time to surface the ground with this material is when the plants are just going out of bloom; in any case it should be applied before the fruit is half-grown. Some means must be adopted to protect the fruit from birds. Scarecrows are of very little use. The general plan is to net the beds. Netting is cheap, and should be freely used in all fruit gardens, especially where ground is limited, and every pound of fruit is valuable. The common plan is to lay the nets over the plants and remove them when the fruit is gathered; that method will answer, but it is clumsy in comparison with spreading the nets over the beds 5 feet from the soil. Stakes driven in the ground at convenient distances, and roof-laths tacked from stake to stake, form a frame which is quickly made, and over which the nets can be spread and pegged to the ground all round. One has only to draw aside the net to gain admittance, and the fruit can be gathered in comfort. Moreover, time is saved in covering and uncovering, and the net is much less liable to rot than if laid direct on the bed. *James A. Paice.*

NOTES FROM AMERICA.

EFFECTS OF THE WINTER IN THE ARNOLD ARBORETUM *

THE winter of 1917-18 has been one of the severest in New England of which there is any record. In December, when the ground was without a covering of snow, the thermometer did not rise from above zero for nearly a week, with a minimum of 17° below. There was little snow at any time during the winter, and the ground, which froze to a depth of from 5 to 7 feet, was not clear of frost until after April 1. Abundant rains late in the summer and in the early autumn, and the fact that the cold has been continuous through the winter without periods of warm weather, which in this region often excite dangerous vegetative activity, have enabled many plants to survive the extreme cold, which, under less favourable conditions, would probably have destroyed them. Still it seems safe to predict that any tree or shrub which has lived here through the past winter will be able to resist successfully a winter in Massachusetts. The condition of the plants in the arboretum at this time is of general interest, therefore as an indication of the trees and shrubs of recent introduction which can be successfully grown in this climate. It must, however, be remembered that local conditions, that is, conditions of soil, position, moisture and dryness, influence the hardiness of plants, and that a tree which succeeds in the arboretum might not be hardy in another garden in the same general region.

The Conifers which have been killed are the glaucous-leaved Mt. Atlas Cedar (Cedrus atlantica glauca), which has been kept alive for several years in a protected position; young plants of the Spanish Fir (Abies Pinsapo) which has been killed before in the arboretum; Abies magnifica of the California Sierra Nevada; Abies cephalonica var. Appollinis from the mountains of Greece; Picea Sargentiana, one of the new Spruces from Western China; and nearly every plant in a large collection of the short-leaved Pine of the Eastern United States (Pinus echinata). These Pines were raised at the arboretum twenty years ago from seeds gathered on Staten Island, New York, the northern limit of the range of this tree, and appeared to be perfectly hardy until this year. On several Conifers the buds are uninjured, and are beginning to swell, although the leaves have been more or less browned by the cold and will soon fall. Conifers injured in this way will probably recover, although their growth for the year will be necessarily checked. Among the trees with injured leaves and uninjured buds are the Cedars of Lebanon from the Anti-Taurus in Asia Minor, which have been growing in the arboretum for sixteen years without protection, and which it was hoped would be able to support the worst conditions New England winters could offer. Other Conifers with injured leaves are the Sugar Pine (Pinus Lambertiana) from the Sierra Nevada of California, the Mexican White Pine (Pinus Ayacahuite),

FIG. 100.—THE KEW PLANT OF THE WHITE FLY BUTTERCUP. (See p. 254.)

* *Bulletin of Popular Information*, New Series, Vol. IV., No. 1, Arnold Arboretum, Harvard University.

the Chinese Hemlock (Tsuga chinensis), which has lost most of its top, and Abies cephalonica from the island of Greece. One or two specimens of this tree will probably not recover. The leaves of the California Incense Cedar (Libocedrus decurrens), of Abies grandis, of Abies amabilis, and of the Hemlock of the north-west coast (Tsuga heterophylla) are slightly injured. The native White Cedar (Chamaecyparis thyoides) is badly hurt, and some of the plants will probably die. The Red Spruce (Picea rubra) from northern New England has suffered badly, as have the plants of the upright form of Juniperus communis from central Massachusetts. The leaves of Abies amabilis, too, from the Cascade mountains of Oregon, are slightly browned, as are those of several plants of the Japanese Abies sachalinense. On a few of the plants of the Chinese White Pine (Pinus Armandii), of the Japanese Pinus densiflora and P. Thunbergii, and of the Chinese Pinus sinensis var. yunnanensis and var. denudata the leaves are also brown. There is no reason, however, to doubt that these will all recover. It is interesting that, with the exception of four exotic Conifers, three of which have been kept alive in the arboretum with much difficulty and have now perished, the most serious damage of the winter to Conifers has been to four native species, Picea rubra, Pinus echinata, Chamaecyparis thyoides, and Juniperus communis. All the new Spruces and Firs from Western China, with the exception of Picea Sargentiana, are uninjured, as are practically all the Chinese Pines. Uninjured, too, are the Carolina Hemlock (Tsuga caroliniana), the western Arbor Vitae (Thuya plicata), and the Spanish Pine (Pinus nigra tenuifolia), which, judging by the climate of the regions where these trees grow naturally, might well have suffered from the cold of the past winter.

Of the new trees with deciduous leaves introduced by the arboretum from China, the following are uninjured: all the Oaks, Elms, Birches, Nettle-trees, Beeches, many of the Cherries, the Pears and Apples, Davidia, Eucommia, and Ehretia acuminata.

Fortunately frost this spring did not injure the buds of many of the trees and shrubs which open their flowers in April. Several of these have been unusually fine this year, and have remained in good condition for a longer time than usual. After some of the Willows the earliest shrubs in the Arboretum to bloom this year were the Buffalo Berry (Shepherdia argentea) and the Leather-wood (Dirca palustris).

PLANT NOTES.

GLOBULARIA CORDIFOLIA.

In his fascinating book, *Among the Hills*, Mr. Reginald Farrer speaks of the "misty pale-blue clouds of Globularia cordifolia," mingled with the native Pansies. It is not given to the British gardener to enjoy in his garden this alpine beauty on such a scale as Mr. Farrar saw it, yet a few plants will give pleasure of no mean kind, and will supply the rock garden with a feature of decided interest. Of the several species of Globularia in cultivation G. cordifolia is one of the prettiest, while it is also of easy cultivation. The plant is not very floriferous in cultivation, but the cushion of deep green, glossy, cordate leaves beneath the blue, Daisy-like flowers, is very attractive. The plant grows wild among other herbage; in gardens it sometimes suffers injury from being too much exposed.

Yet if planted in cool soil, near the base of the rockwork in a level spot, and given plenty of water in prolonged dry weather, it will generally do well and flower with a moderate amount of freedom. A top-dressing of loamy soil applied in spring and autumn will induce roots to develop from the stems. *S. Arnott.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey

PLANTING WINTER GREENS.—Brussels Sprouts, Broccoli, Kale, Early Savoys, Cauliflowers and other greens still in the seed-beds should be planted out, if possible, in showery weather. A good practice is to draw a shallow drill in which to dibble in the plants. Where the quarters are not yet vacant for them the plants should be pricked out in a fresh bed to prevent them from getting drawn. Broccoli needs plenty of room, and should be allowed a space of not less than 2½ feet each way. One of the causes of Broccoli failing to withstand the winter is being planted too closely in over-rich soil. This crop should be planted in firm ground, and no manure should be used on land that is in good condition; on the contrary, Cauliflowers intended for use in the autumn should be put out on well-enriched ground, and encouraged to grow without loss of time, to make large heads.

EARTHING-UP CROPS.—The importance of earthing up most kitchen-garden crops cannot be over-estimated. Early Potatos are generally earthed up in good time, the operation being repeated as the plants increase in growth, mainly to protect the haulm from frost. The soil should be drawn up to Maincrop Potatos when the tops are 8 to 10 inches high. Before earthing-up break up the soil with a fork without disturbing the tubers in the rows; in the case of light soils use the hoe freely in the rows to destroy weeds and break the soil to a fine tilth. All the members of the Brassica family, Broad Beans, Peas and Kidney Beans are benefited by frequent hoeings, which check evaporation of soil moisture and, disturbing the soil, allow the rains to soak in more freely.

CELERY.—Plant out later batches of Celery when the plants are about 4 inches high, in single or double rows, as convenience allows, as recommended in the Calendar for May 17. If the plants are allowed to become too large they will receive a check when transplanted and take considerable time to recover. Keep the plants well supplied with water during dry weather, and give plenty of moisture to Celery that is already planted. Give frequent light dustings of soot when the plants begin to grow, applying the material when the foliage is wet with dew.

TOMATOS. Young plants that have been treated as advised in previous Calendars should be suitable for planting either under glass or in the open. Houses that have been cleared of French Beans or other crops should be cleansed and filled with strong Tomato plants. Tomatos do not require a very large amount of soil; the main point is to use a fairly rich compost and make it firm. When the fruit is swelling give frequent top-dressings of rich soil mixed with guano or other stimulant, and water the plants occasionally with weak liquid manure. Tomatos succeed best when growth is restricted to a single stem, removing all side shoots as they appear; they should be planted not closer than 15 inches apart and fully that distance from the roof-glass.

COLEWORTS.—Directly frosts destroy Peas, Beans, and other somewhat tender vegetables there is a demand for Cabbages. It is therefore advisable to sow seed now of Rosette Colewort and in ten days' time Hardy Green Colewort. If these sorts are sown rather thinly on an open piece of ground the plants will be ready for putting out as the land is cleared of early-maturing crops. Plant at 12 to 15 inches apart each way. The plants will give tender hearts from October to mid-winter or later, according to the weather. Amateurs especially should grow this vegetable to ensure a good supply of greens in the winter.

SLUGS.—These pests have been very troublesome this spring, and have injured all tender vegetation. It has been difficult to get seed to germinate in the open, but more difficult to preserve the seedlings from injury by slugs. Those who sowed seed under glass to obtain plants for transplanting have every reason to congratulate themselves. Frequent rains have washed off dressings of soot and lime as soon as they were applied to the plants. Where allowance for losses was not made in sowing, the defects must be made good at once by sowing fresh seeds.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

STRAWBERRY PLANTATIONS.—The first opportunity should now be taken to prepare the earliest Strawberry beds for the ripening of the fruit. Hoe the ground thoroughly—more than a mere surface hoeing. A fairly good dressing of lime should be shaken around each stool, and well under the foliage, as a deterrent to slugs. Litter need not then be applied until the fruit is on the point of colouring. Defer this operation as long as convenient in order that the soil may become warmed by the sun. Damage to the plants may be prevented by fixing the netting in advance of the mulching, with walking-room under the nets. On shallow soils it may be advisable to water the beds freely in advance of the ripening, but do this with clean water; never use liquid manure for this purpose. Pour the water directly into the crowns of the plants. In order to keep the fruit off the ground wire supports can be used, which may be obtained from almost any sundriesman. Mid-season and late varieties should receive attention in due course. Plants recently put out from their fruiting-pots will need close attention, and watering must not be overlooked. A little shading from very hot sunshine will be an advantage; for this there is nothing better than a handful of long litter laid on the top of each crown. The Perpetual varieties should now be growing freely. Do not let them develop any fruiting spikes yet. Keep the trusses pinched out until the first week in July, but still peg down an occasional runner; they should fruit this autumn. Damp the beds over towards the evening to encourage clean growth.

PLUM TREES.—Apparently, Plum trees are not likely to bear even a moderate crop this season. Fly is a little troublesome, but can be held in check by vigorous syringings with a suitable insecticide. With a thin crop an opportunity is afforded of taking off an occasional branch, to make the trees more shapely. An artificial manure, containing a fair percentage of phosphates and potash, will help the trees to bear better another season. If any trees show signs of Silver Leaf disease remove the affected branches and burn them at once.

THE ORCHID HOUSES

By J. COLLIER, Gardener to SIR JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

CATTLEYAS AND LAELIAS.—Cattleya Mendelii, C. Mossiae, Laelia purpurata, and many hybrids from these species, are in the height of their flowering season. In the case of plants that are not well rooted the flower-spikes should be removed directly they appear, or cut as soon as the flowers are fully developed. As any of the above-named plants pass out of flower they should be looked over to ascertain if additional pot-room or new material is needed. Plants of C. Lawrenceana, C. Schroderae, and others that flowered at an earlier period, and have just had a short season of rest, will soon commence to grow afresh, and should be repotted or top-dressed as found necessary. For a few weeks after repotting careful watering is necessary, and, until well rooted, a little extra shade should be employed. The plants should be sprayed overhead two or three times every day during bright weather. Cattleya Warscewiczii (gigas), C. Dowiana and its variety aurea, C. Warneri, C. Gaskelliana, and others that produce their flowers during the summer months are now making new growth, and should be placed in the warmest and brightest position in the Cattleya house. Apply water more liberally at the roots, thoroughly soaking the compost, but allowing it to become moderately dry between each application. A few of the earliest plants will be producing their flower-spikes.

Any specimens that do not bloom may be repotted, if necessary, as soon as they commence to root from the current pseudo-bulbs.

DENDROBIUM.—Plants of the evergreen section of Dendrobium, such as D. thysiflorum, D. chrysotoxum, D. Brocklhartii, D. densiflorum and D. Farmeri, should be kept cool and the roots dry for a short period after they have passed out of flower. The necessary repotting or resurfacing should be attended to as soon as fresh roots develop from the base of the young growths. The plants should not be subjected to root disturbance until it is found to be really necessary, as they flower most freely when pot-bound. While the plants are in active growth they should be placed in an ordinary plant stove or Dendrobium house, but when the pseudo-bulbs are fully developed they should be grown in a slightly cooler temperature. The cooler-growing D. infundibulum and D. Jamesianum may also be given attention if a large receptacle is required or the compost has become sour and decayed. All this section ought to be potted firmly, in a mixture consisting of Osmunda-fibre, A 1 fibre, and Sphagnum-moss in equal parts. Young shoots of the deciduous and semi-deciduous sections are growing freely, and developing new roots quickly. The plants should be more liberally supplied with water, and the young growths supported by looping to the old pseudo-bulbs or to neat stakes. Do not allow them to bend over the sides of the pots, as they might become permanently injured. If any of the plants have filled their receptacles with roots, the present is a suitable time to shift them into larger pots. They should be taken out without unduly disturbing the ball and placed in larger pots, the space around being filled in with compost.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to MRS. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

FIGS. Houses containing trees on which the fruit is ripening should have plenty of air admitted during the day and a liberal amount through the back ventilators at night. Even though the weather be warm and genial, fire heat will still be necessary to obtain good colour and high flavour in the fruits until the nights get warmer. Sudden fluctuations in the temperature at this period will cause the fruits of the second crop, which are swelling rapidly, to drop. If the crop be a heavy one, thin the fruits before the energies of the trees are unduly strained. It is not advisable to remove all the smaller fruits; rather leave a fair number, provided they are of good shape, thus securing a succession of ripe Figs over an extended season. The use of warm, diluted liquid manure at every other watering will increase the size of the fruits, or failing this stimulant, apply a top dressing of rich materials. Trees trained near the roof glass are very subject to attacks of red spider, making it a difficult matter to keep the pest in check when the fruits are ripening. Use the syringe freely, damping the bare spaces and branches daily without wetting the fruit; the trees themselves may be syringed from time to time directly the ripest fruits are gathered. The work of stopping, thinning and tying the shoots should be continued, as good Figs cannot be obtained unless the sun's rays reach them and the air circulates freely about them. Some of the shoots will only need to be pinched once according to the space available, others twice, but as every shoot stopped makes a new growth the young wood must ripen thoroughly or it will be of little value for next year's fruiting.

EARLY PEACH TREES.—Not only is it good practice to remove the old fruiting wood and superfluous growths from Peach trees directly the fruit is gathered; it is necessary to allow the sun's rays and air to enter the tree freely to thoroughly ripen the young wood for next year's fruiting. Tie in the most healthy and best placed shoots not closer than 4 inches apart. See that the trees are free from insect pests, using, if necessary, an insecticide. Increased ventilation day and night, with syringings of clear water twice daily, will give the young wood the nut brown appearance that indicates ripeness.

CHERRIES.—Keep houses containing ripe Cherries cool and well ventilated. Light scrim, tiffany, or nets thrown over the roof during hot weather will prolong the fruiting season and keep the Cherries safe from birds. Assist the formation of fruit-buds by pinching all shoots not required for the extension of the trees to a few leaves. The soil should be kept moderately moist only: an excess of moisture at this stage would cause the fruit to crack.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

CALADIUM.—These ornamental-leaved plants are in active growth, and need strict attention in watering. When the pots are filled with roots stimulants should be used, or the plants will soon deteriorate. Diluted soot water is an excellent stimulant for Caladiums, and it helps in a great measure to intensify the colouring of the foliage. Some of the larger plants may need their leaves regulated and tied neatly to stakes. Caladiums should on no account be exposed to bright sunshine, or the leaves will be scorched; on the contrary, they must not be shaded to excess.

CANNA.—For ordinary decorative purposes Cannas are best grown in pots about 6 inches or 7 inches in diameter. They must, however, be very liberally treated in the matter of watering and feeding, or many of the plants will fail to flower. If it is necessary to repot the plants, use a rich compost and make the soil firm. The plants may be grown in an ordinary greenhouse.

FORCING SHRUBS. Azaleas of the Ghent and mollis sections should receive attention during the next few weeks, for neglect of the plants now will have a prejudicial effect on next season's flowers. Specimens which have not been repotted this year should be given liquid manure made from farmyard dung and soot water; the stimulant should be given at every alternate watering. Syringe the plants vigorously every evening during hot weather, and, should red spider be noticed on the foliage, use an insecticide late in the evening, repeating the syringing every third evening for a week or ten days. The pots should be plunged in ashes in a position which is well exposed to the sun. Lilacs which have been forced should be planted out without delay, and the same remark applies to all forcing plants which are intended to be planted in the open. Keep the roots well supplied with water till they become established. Plants of Prunus triloba have completed their growth, and may be plunged in a bed of coal ashes out of doors.

GARDENIA.—Plants of Gardenia may either be grown in pots or planted out. In any case, they should be grown fairly close to the roof glass. Considerable heat and moisture are necessary while the plants are making their growth, and the foliage should be well syringed with tepid rain water twice daily in hot, sunny weather. Established plants may be given stimulants on two or three occasions weekly. Mealy bug, thrip, and red spider often attack Gardenias, but all these pests may easily be destroyed by syringing the plants with a suitable specific at regular intervals. A batch of young plants should be propagated every spring from cuttings. It is not wise to retain old plants after their second season.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

BIENNIALS.—If sown early, an opportunity to transplant seedling biennials may be taken, less trouble being involved to transplant small than large seedlings. Generally, spaces of 10 to 12 inches are sufficient for all biennials intended for autumn planting to develop their growth. Well-rotted manure forked into the surface will give the plants a good start, and they should be very firmly set in the ground. Summer attention consists in frequent hoeing of the soil; it is a mistake to wait until weeds have grown so much that hoeing is imperative.

PLANTING IN FIRM SOIL.—I have repeatedly found that plants recently planted which showed signs of retarded growth suffered from the soil being loose. Following foot compression there is immediate change for the better, and much labour is saved in watering. Daily watering of loose soil in hot weather is without much value to the plants, whereas moisture is retained in firm soil, and the need of the application of water obviated.

STAKING. For the past three years I have staked scarcely any hardy plants. Formerly the supporting of plants when called for the use of thousands of stakes, with their removal and storing at the end of the season, necessitated much labour, which cannot now be obtained. Accordingly, I extended a practice which was in use for a few subjects, and which consisted in removing the tips of the shoots in order to induce the plants to form bushy growth. A large number of border plants are treated in the same manner, leaving a few, of which the Phlox is one, to grow naturally. Some need knifing—the Hollyhock and the double Rudbeckia laciniata being examples. Anchusa italica needs attention more than once, as also the hybrid Lupinus of the polyphyllus class. A reaping hook enables one rapidly to decapitate the plants over a large extent of ground, and if done early the dissevered tips need not be gathered up. The beautiful double rose-coloured Godetia is treated in the same manner, which improves it very considerably, causing the plant to branch more freely and keeping it dwarf and neat. It need hardly be said that those plants, such as Spiræas, Astilbes, Hemerocallis, and others, that require no support, and which to cut over would render flowerless, are not referred to.

THE APIARY.

By CHLORIS

WHEN TO SUPER.—When the bees are very busy during May and June, the hives seeming full of bees, and the top cells of the hives have been tipped with new wax, then add the supers. It will be found an inducement to the bees to start storing above if shallow frames be first used, as the bees are always loth to fill sections. When the habit has been formed, or when the frames are three quarters filled, then the sections can be placed below the shallow frames. A great mistake is often made in connection with supering the racks are not wrapped up warmly enough. There should be no draughts in the hive. Further, the wraps and quilts, being non-conductors of heat, also help to keep the interior of the hive cool during the hottest weather, for what will keep in the heat will also exclude it. As the racks reach the point of being two-thirds to three-quarters full, a new super may be added below, leaving not more than three in all. The top crate will be the first to be removed. Always place queen excluder zinc above the brood chamber, or the queen will deposit eggs, and brood will be raised where it is not desired.

REMOVING SUPERS.—The best method of removing sections or shallow frames is to give the bees a puff of smoke, or use a carbolic cloth, i.e., a piece of calico about 20 inches square which has been sprinkled with a solution made with 1 oz. of Calvert's No. 5 carbolic in 2 oz. of water. Put the mixture in a medicine bottle fitted with a vertically grooved cork, so that the liquid, after being shaken, may fall out in drops. The great advantage of the carbolic cloth (which is rolled up when not in use and kept in a close fitting tin) is that the use of a strong disinfectant is a preventive of foul brood. Care must be taken in handling it or it will very easily blister the skin. The method of using the cloth is to unroll it as the quilt is taken off: the bees will have gone down in a few seconds, when the cloth can be rolled up and any examination made. To return to the method of removing sections after smoking or using the carbolic, the bees will go down, and a board with a "Porter bee escape" should be placed underneath the rack to be removed. By next morning it will be emptied of all the bees, and none of the cells will be found punctured, as often happens when the board is not used. The board should be put on about midday, when few bees are in the hive. Remember when manipulating bees always to stand at the back or side, never in front of the entrance, and never work among them when the weather is chilly or thunderous.

EDITORIAL NOTICE.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER, *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 58.3.

ACTUAL TEMPERATURE:—

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday* June 6, 10 a.m.: Bar. 30.2: temp. 67.0°. Weather—Bright sunshine.

Onion Neck Rot.

In certain parts of the country, at all events, the present season is proving unfavourable to the growth of Onions. Healthy transplanted plants put out a few weeks ago met with adverse climatic conditions, and even now, after the warm spell, are developing in a patchy manner. The rows present a very uneven appearance, and not a few of the plants have developed a weakness at the neck, which causes the tops to bend over and lie prostrate on the soil. Examinations of these plants show yellowish discoloured patches on the leaves, and these patches may be the symptoms of the disease known as neck rot, now ascribed to the fungus Botrytis allii.*

An Onion disease due to a fungus belonging to the genus Botrytis has been known for long, and often described in this country. Thus Massee described (*Gard. Chron.*, August 11, 1914) a Botrytis disease of Onions and attributed it to the work of Sclerotinia bulborum. Inasmuch as the genus Botrytis is widely distributed in the soil, it may be that more than one species attacks the Onion. In any case, both the fungus described by Massee and that now worked out in detail by Mr. Munn agree in the possession of a sclerotium stage, that is, in producing black masses of resting mycelium in the bulbs of stored Onions. Mr. Munn's observations are, unfortunately, not very helpful in assisting growers in combatting the disease. Trials with Bordeaux mixture have given promising results, but as he points out, the prostrate condition of affected plants makes damage during spraying unavoidable. He does not appear to have tried sulphuring—a practice not infrequently adopted by Onion growers in this country.

The formation of sclerotia in Onions in store is well known to growers, who will agree with Mr. Munn that the better the ripening of the bulbs, the more the foliage and necks are removed, and the more well ventilated the store, the less is the disease likely to spread.

Once in the plant, however, the fungus is difficult to check. It spreads from the neck to the leaves, and also downward into the bulb, and even into the roots. Even the flower-heads of Onions grown from seed are susceptible of attack.

Mr. Munn finds that injudicious use of artificials and excess of fresh manure and poor air-drainage of the soil, favour the development and progress of the disease.

In view of the importance of the Onion crop, it is unfortunate that disease should have declared itself so early in the season, and it is to be hoped that it will prove to be of only local occurrence. It would be interesting to know whether autumn-sown Onions are as liable to attack as are those transplanted in the spring, and also whether this year spring-sown Onions, which presumably escaped the miserably damp weather, will also escape the disease.

* *Neck Rot Disease of Onions*, by M. T. Munn, Bull. 437, New York Agric. Exp. Station, Geneva, N.Y.

NO RETURNS.—We wish to draw the attention of our readers to the recent order of the Paper Controller, which prevents the purchase by newsagents of papers on "sale or return." This will necessitate all readers of the *Gardeners' Chronicle* ordering their copies in advance, either from a local newsagent or bookstall, or from the office of the paper, at 41, Wellington Street, Strand, W.C. 2. If the latter course is adopted the paper will be sent by post each week, and the price will be 19s. 6d. for a year, 9s. 9d. for six months, or 4s. 10d. for three months, post free. Occasional readers, who have been in the habit of buying a chance copy of the *Chronicle* only now and again, will, we fear, be disappointed if they try to continue this practice after the 24th of this month, as newsagents will not run the risk of buying odd copies which cannot be returned if unsold.

SOUTHAMPTON ROYAL HORTICULTURAL SOCIETY.—The summer flower show of the Southampton Royal Horticultural Society will be held in the pavilion of the pier on Tuesday and Wednesday, July 23 and 24, 1918. There will be a stall for the sale of horticultural produce for the benefit of the local funds of the British Red Cross Society and Order of St. John. The Society has also arranged to conduct a floral stall at the Rose show, to be held at South Stoneham House grounds on Wednesday, June 26, in aid of the funds of these two societies.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The Committee of the Gardeners' Royal Benevolent Institution makes an urgent appeal for support for the Fund. The enforced abandonment of the usual festival dinner has closed that source of income, with the result that there has been a deficit in the past three years of £1,000 each year. This has been met by drawing upon a small reserve, which is now nearly exhausted. Over 260 aged gardeners and wives of gardeners are dependent upon the annuity to which they were elected for life, whilst the claims for temporary assistance from distressed applicants are as urgent as ever.

U.S.A. SEED TRADE CONVENTION.—The convention of the American Seed Trade Association will be held this year at Chicago, on June 18, 19 and 20. The convention meetings will be held at the Hotel Sherman.

NEW NAME FOR AN OLD VEGETABLE.—The competition for the purpose of obtaining a new popular name for Helianthus tuberosus, hitherto known in British gardens as the Jerusalem Artichoke, has resulted in the judges—Miss ELLEN WILLMOTT, Sir FRANK CRISP, and Mr. WILLIAM ROBINSON—selecting "The Sunroot" as the new title for the plant. Ten competitors gave this as the best name, and each is awarded a prize.

PRESENTATION TO MR. G. F. HOOPER.—Mr. G. F. HOOPER, for the past nine years president of the Pershore Co-operative Fruit Market, has received presentations from the committee and members. The presentation was made by the new president, Mr. F. R. Pearson, who said that those associated with the market were desirous of showing their appreciation and affectionate regard for Mr. HOOPER, as well as to express their thanks to him for the able manner in which he had filled the office of president for the past nine years.

VEGETABLE MARROWS FOR JAM-MAKING.—Estimates made by the Food Production Department indicate that this year's fruit crops will be insufficient to supply the jam factories with the fruit required for jam-making purposes. In view of the great importance of sufficient supplies of jam being available for use by the Navy and Army, and by the civilian population, the Department is appealing to cultivators to plant immediately and on as large a scale as possible Vegetable Marrows for supplementing the fruit supplies available for the jam factories. The Department is authorised by the Sugar Commission to announce that there is no prospect of any further allowance of sugar becoming available for the household making of jam from Vegetable Marrows. Therefore, the Vegetable Marrows grown in response to this appeal should be either sold to jam-making factories or stored for use during the winter. Thousands of tons of ripened Vegetable Marrows can be utilised during the coming season by the jam manufacturers.

GEOGRAPHICAL DISTRIBUTION OF PLANTS.—At the twenty-third annual congress of the South-Eastern Union of Scientific Societies, held at the rooms of the Linnean Society, Burlington House, the new president, Sir DANIEL MORRIS, delivered his presidential address on May 29, the opening day, when he took for his subject "A Chapter in the Geographical Distribution of Plants," illustrated by lantern slides. Sir DANIEL called attention to the fact that up to the time of DARWIN it was believed that the same species of plants must have been independently created at different points, but the great Victorian scientist contended that all of the same genus originally came from the same species. That theory revolutionised geographical botany. A single seed might stock a whole island, whilst small seeds were distributed like dust by the winds. In some cases birds were much more effective agents of distribution than the wind, and even insects were able to disseminate small seeds. The part taken by ocean currents and the tides in the scattering of seeds and fruits was enormous, and the phenomena could be observed at their best in the tropics, a knowledge of beach and littoral plants being essential to accurate conclusions.

WAR ITEMS.—Lance-Corporal CECIL SMITH, Royal Irish Rifles, son of Mr. GEO. NORMAN SMITH, and grandson of Mr. THOS. SMITH, of the Daisy Hill Nurseries, Newry, is officially reported missing since April 15. Lance-Corporal SMITH, who had served three years in a North of Ireland camp, attained his nineteenth birthday the week before he left for the Front. His elder brother is an officer in the Royal Flying Corps.

—— The two sons of Mr. W. R. DEAKIN, fruit-grower and jam manufacturer, Pershore, have gained the Military Cross. Capt. W. G. DEAKIN, Royal Horse Artillery, has recently won the Cross, and his brother, Lieut. G. DEAKIN, R.E. has won the Cross and a Bar to it.

—— The late Major J. L. VEITCH was recommended for the Military Cross after his good work in the critical days of April 12, 13 and 14. The announcement that the honour was conferred did not appear in orders until after he was buried.

DRIED APPLES FROM AUSTRALIA.—The British Government has agreed to purchase 1,800 tons of Australian evaporated Apples for shipment at the rate of 300 tons a month from March to August of the current year. The price is 15 cents per pound.

ON INCREASED FOOD PRODUCTION.

CLIMBING HARICOT BEANS.

I ADVISE those who intend to grow these Beans to consider the following points before they make the attempt: Is the summer long enough for the Beans to mature, and is there ground to spare for a chance crop; also will Bean-sticks be available, and their cost? We may rely on Potatos, Onions, Carrots and Leeks as certain crops, but success with climbing Haricots is doubtful. Last year I grew four rows, each 40 yards long, of these Beans. I tried some of the young pods cooked green, but they were tasteless, and before a good crop of Beans had formed in the pods early frosts appeared. I do not mean to imply that the crop was a failure as a whole, but these Beans are not worth growing for winter use by allotment holders and others who have only a little ground.—*C. Dodds, Holy Well Park Gardens, Ipswich.*

DAMAGING CROPS AN OFFENCE BY LAW.

WITH the concurrence of the Home Office, the Board of Agriculture has obtained an amendment to the Defence of the Realm Regulations by which it has been made a summary offence to damage growing food crops.

According to the Food Production Department representations have been received from various parts of the country to the effect that in view of the large extension of cultivation the existing legal provisions are not sufficient safeguard for the farmer's crops. In future, any person who without lawful authority or excuse damages any growing crop or any hedge or fence on any agricultural land, is liable to a fine of £100 or six months' imprisonment with or without hard labour, or both. The offence is triable by a Court of Summary Jurisdiction, but a prosecution can only be instituted by a police officer or by a person authorised by the Government Department concerned. No notice need have been displayed on the land in question to prove an offence when damage has been committed. If the damage is done by a crowd (which frequently happens when aeroplanes alight on cultivated land), any member of the crowd is deemed to have caused the damage unless he proves the contrary.

It will be noted that the regulations strengthen the law of trespass between allotments or field gardens and farms. It is an offence to trespass upon an allotment where a warning notice in the prescribed terms has been duly displayed, whether actual damage to crops or fences has been done or not. Only where damage is done has the farmer the holder of agricultural land or immediate remedy against the trespasser. All land which has been taken over by a Government Department or any body or person authorised by a Government Department is protected exactly in the same way as allotments or field gardens whatever the purposes to which it may be put, that is to say, entry thereon without lawful authority or excuse is in itself an offence.

CATERPILLAR ATTACKS.

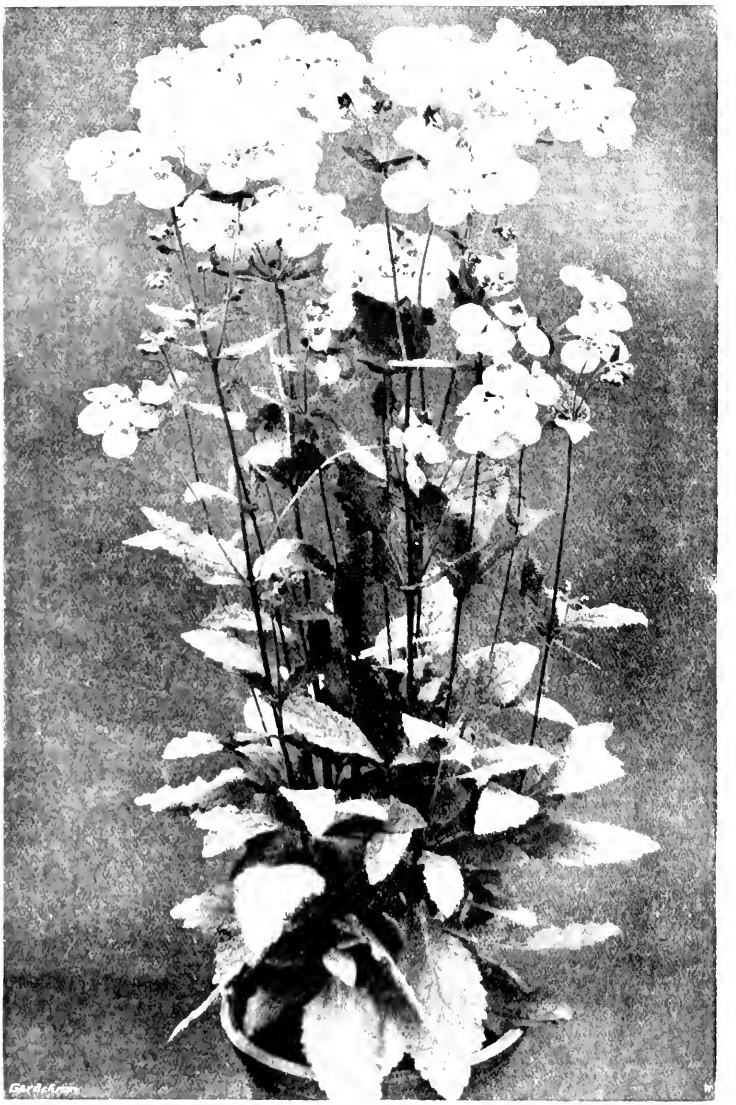
FRUIT trees are suffering from bad attacks of caterpillar in many districts, and fruit growers are urged to spray their trees without delay with a solution containing 1 lb. lead arsenate paste to every 10 gallons water. This spray fluid, if applied properly, will kill the caterpillars and prevent further defoliation. The application should be made in a fine spray sufficient to wet the leaves without drenching them.

Care must be taken that no vegetables or green Gooseberries grown in the neighbourhood of the sprayed trees are gathered for consumption within a month of the application, as lead arsenate is a very poisonous chemical; nor must trees in full bloom be sprayed, as otherwise bees and other insects useful in pollinating flowers may be killed.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by correspondents.)

ANEMONE NEMOROSA ALLENII (see p. 229).—The soil of my present garden is heath-like and, apart from being exceedingly light, quickly becomes dust dry. Anemone nemorosa Allenii while growing and increasing freely, never has the beautiful colour it assumed in my old garden in Middlesex, although the vigour of leaf and rhizome is equal, if not superior. In the variety Robinsoniana there is also an appreciable falling off in colour, while vigour and increase of growth is well maintained. The one that has lost nothing in respect of colour and grows and increases more freely than ever is purpurea, and a group of plants bearing a hundred or so of its lovely blue flowers—the varietal name is a misnomer so far as the expanded flowers go—has been a beautiful picture this spring. Generally, however, finer colour and greater vigour in these plants follow planting in cool, moist, or even wet loams; a condition of things which synchronises with those in which the typical kind is often found wild. Dry, heath-like soils are only favoured by the plant, while in exposed positions in such ground the flowers are shortlived. Hence there is more than one reason for planting these Anemones in moist places. Transplanting may be done at any moment now; the one thing to avoid is the rhizomes becoming dry.—*E. H. Jenkins, Surbiton, Surrey.*



[Photograph by E. J. Wallis.

FIG. 101.—CALCEOLARIA MEARDII: FLOWERS YELLOW. (See p. 234.)

LEATHER-JACKETS.—Referring to the statement in *Gard. Chron.*, p. 218, that leather-jackets are difficult to eradicate, a person present at a lecture given at the Reading University

College stated that he had covered the whole of his plot with the light-greenish ammonia from the local gasworks, and after a time dug it and planted his crops as usual. Everything flourished, and roots especially, such as Potatos, Onions and Turnips, but Parsnips, though fine, when dug up had leather-jackets sticking half-way out of them. Some present stated that they were afraid to use ammonia, and thought it would burn the vegetables. *L. J.* [Might not the speaker have confused ammonia with gas lime? —EDS.]

PROLIFIC PEAS.—Growing here in a cold house we have three late Queen Peas, which at the time of writing are 4 feet 6 inches in height with haulms one quarter of an inch thick. These Peas have thrown out ten extra haulms, all of which are carrying flower-buds. The three plants are together bearing about 65 pods, flowers and buds, with a goodly promise of a fair number more. What appears to be remarkable with regard to the above Peas is that the seeds were in the pods on the haulms in the garden up to November 5, 1917, in a green state, and quite eatable, but were found to have sprouted. Out of curiosity the Peas were sown the next day, November 6, in a 6-inch pot, and grown in a temperature of approximately 55°. Rather surprisingly, the first one made its appearance above the soil on November 15, the others following in a day or two. The plants were transferred to the border in the cold house about the middle of last December, with the above results. *A. Bagg. Bishop's Hall Gardens, near Romford, Essex.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

MAY 23.—*Present:* Mr. E. A. Bowles, M.A. (in the chair), Dr. A. J. Voelcker, Messrs. W. Hales, J. Fraser, W. C. Worsdell, E. J. Allard, J. W. Odell, and F. J. Chittenden (hon. secretary).

Ornithogalum refractum.—Mr. Worsdell reported that he had examined the Ornithogalum from Salonika shown at a recent meeting by Mr. Bowles, and had come to the conclusion that it was O. refractum.

"Thorn" Apple.—Mr. Worsdell showed flowers of the curious Apple called "Thorn" Apple shown some time ago from Over Wallop. The flowers had all the petals and stamens converted into sepals, the "fruit" being formed of the fleshy bases of the latter. The ovary was apparently normal.

Paeony from Salonika.—Mr. Bowles showed a flower of a dark wine red form of Paeonia officinalis from a plant collected in Salonika.

Primrose with foliose corolla.—Mr. Bowles also showed a Primrose with a corolla with green petals and midrib and veining of ordinary leaves. The form came originally from Messrs. Cocker, of Aberdeen. The calyx was more or less dialysed

CROPS AND STOCK ON THE HOME FARM.

MANGOLD.

MANGOLD seed germinated splendidly, the plant coming through the soil in remarkably short time where sowing was done in favourable conditions and fine soil. The Mangold loves sunshine, hence the favourable good initial start. Unfortunately the Turnip fly had attacked the seedlings in the majority of cases that have come under my notice, in some plots destroying patches of the plants, and in others wilting the leaves badly, giving a check to growth. The best method of checking this pest is to disturb the insects in some way; rolling the field early in the morning while the dew is still on the leaves is successful. Where the plant is large there is, however, a risk of crushing the leaves by the roller. Horse-hoeing between the rows or flat hoeing is useful in that the moving of the soil accelerates growth, and naturally has a double effect on the plant.

In small areas spraying with petroleum emulsion or drawing tarred bags over the plot would destroy much of the fly, but it would be a difficult matter to treat acres of the plant in this way. Where no manure was used at sowing time, sow evenly over the plot half a hundredweight of sulphate of ammonia per acre: the fertiliser will give a fillip to the plant and hasten growth out of harm's way.

HAYMAKING.

In southern counties grass cutting is in full operation. The crops of Italian Rye grass, Clover, Trefoil, Sainfoin and meadow grass have grown very fast. It is not wise to delay the cutting of these crops for too long, as when the crop is old the quality of the hay is depreciated. Field grass, as Sainfoin, Clovers, and the various grasses, does not require so much manipulating to dry as meadow grass. One turning is sufficient before the crop is collected for carting: in the case of Sainfoin and Clover, repeated turning breaks the leaf, which is the prime part of the hay.

With a scarcity of labour more use should be made of machinery, such as grass cutters, swath turners, side-rakes, and sweeps: the use of the last in many instances dispenses with carting entirely when the rick is made in a convenient part of the field. Swath turners are admirable labour-savers, and by their use a stout nag horse will turn twenty acres in a day much better than a dozen men or women can do the same work by hand.

Meadow hay provides the best food for dairy cows and nag horses. The grass should not be too old when cut, neither should it be allowed to become too dry before it is put into the rick. Sufficient heat should generate through the whole to infuse an aroma when cut from the rick, and the colour should be even then green. Some persons favour the building of small ricks. I prefer one of twenty tons. The larger stack is economical to build and thatch, and there is very little waste at the top, bottom, and sides. The shape of a rick is an important matter. A flat roof admits moisture under the thatch, spoiling several inches of hay. I know of no better style of rick than that practised in Hertfordshire, which is sharp pitched. I have never seen "fusty" hay from the roof of such a shaped rick. Directly a rick has settled down the sides should be tucked and shaped and the roof made up with the tuckings, which should be raked down quite smooth to ward off rains until the whole has settled sufficiently for thatching.

When the first heating has taken place thatch the rick thickly at once as a safeguard against heavy rains. Where obtainable, Dutch barns are a boon, saving labour in many ways. Into these the hay can be carted a little at a time and with safety. *E. Molyneux*

ANSWERS TO CORRESPONDENTS.

ABNORMAL DELPHINIUMS: *A. T. H.* The flowers you send are what is known as "Pelorie," a not uncommon peculiarity, especially among normally zygomorphic flowers. Apparently all the flower-forming capacity of the plant has become concentrated at the point of the spike, instead of being distributed along it. As the condition is apparently hereditary, and is by no means an improvement, but rather the reverse, we should advise you to dig up and destroy all the plants displaying it.

CLOCK GOLF: *G. R. R.* Form, on a smooth lawn, a circle having a diameter of from 25 to 35 feet. Divide it at the circumference into twelve equal parts, and number the divisions like the dial of a clock. Sink a hole 3 inches across and 4 inches deep at a spot inside the circle, near the figure six on the dial, placed in such a way that no two of the twelve points are at exactly the same distance from it. The art of the game is to "putt" a golf ball into the hole in the fewest possible number of strokes while playing from the twelve points around the circle. Another method of marking out the ground is to set out twelve points, numbered one to twelve, quite irregularly over the lawn, arranging them so that no two are equi-distant from the hole.

FLY ATTACKING POTATOS: *Hortus, Mansfield* The insect attacking your Potatos is the Potato flea beetle (Psylliodes affinis). Dust the plants by means of bellows with Bclummite.

LEAF SOIL: *M. M.* The leaf-mould seems quite suitable for mixing with potting soil, but should not be used by itself. It should also be rubbed through a fine sieve before being mixed, as many of the leaves are not sufficiently decayed to be of any use. It is not possible for us to ascertain whether any acid or poisonous substance has been sprinkled over it, but we do not think this can be the case, as two or three healthy seedlings of weeds were present in the sample sent.

MARROWS AND CUCUMBERS: *M. G.* For planting Marrows, make a hole 2 feet wide and 1 foot deep, and fill it with a mixture of half partially-decayed dung and half soil, placing the spare soil around the hole to form a basin 18 inches in diameter. Frame Cucumbers should be planted in a similar compost to that for the Marrows, adding a covering of the same material 1 inch deep every time the roots appear on the surface.

NAMES OF FRUITS: *F. F.* Hormead Pearmain.—*H. H.* Norfolk Stone Pippin.—*E. C. K.* Broad-eyed Pippin.

NAMES OF PLANTS: *Conifers, P. T.* 1, Abies nobilis: 2, Pseudotsuga Douglasii (Douglas fir).

OUTSIDE VINE BORDER: *Miss G.* Should the weather continue dry, your outside Vine border would be benefited by a light mulching of partially decayed animal manure, after pricking up the surface with a fork, 1 inch deep, and then giving a heavy watering over the manure, say, six gallons to the square yard, in two applications. When the rods are 4 feet apart, three leaves may be left beyond the bunch, which generally appears opposite the fourth or fifth leaf. If closer than 4 feet, only two leaves should be left. Remove all sub-laterals excepting the one (should there be one) springing from the base of the lower leaf-stalk, and keep this stopped to one leaf.

RAISING BRIARS FROM SEED: *Rosa Canina.* There is nothing special to observe in the harvesting of Briar seed. Gather the heps when they are quite ripe and bury them in a heap of sand. The sand should be moist and kept indoors where birds and mice cannot reach the seeds. Rub out the seeds, and sow them thinly in shallow drills in a sandy compost, if possible, in a frame where birds and mice cannot reach them. The seedlings will appear in about three months from the time of sowing. Do not allow the soil of the seed-bed to become dry, but an excess of moisture is harmful. When the seedlings are about 2 inches high, transplant them in sandy soil in rows made 1 foot apart, and place the plants about 1 inch apart in the rows, or wider if there is plenty of space. It is well to sow early in the year, or even in December, if you can keep frost out of the frame

RED SPIDER ON PEACH TREES INDOORS: *J. R.* If red spider is still present on the trees after syringing with clear water, use an insecticide such as Quassia extract. The stock, the variety or the condition of the roots may be the cause of the trouble; the roots should be lifted in the autumn and some of the old soil replaced with fresh compost.

SPONGE WASTE: *Dr. S., Bombay.* Sponge waste may be purchased from Messrs. Cresswell Brothers, sponge importers, 18 and 19, Red Lion Square, W.C. 1.

VINES: *Kuban, Dublin.* In reducing the number of leaves on the Vines, first remove all laterals but one from each spur, and all sub-laterals excepting the one springing from the base of the lower leaf on the remaining shoots, keeping this shoot stopped to one leaf. In a few days' time you might shorten the shoots a little, if the leaves are still crowded, but the removal of a large quantity of leaves from these shoots at one time would check the growth of the fruit. When the rods are below the supporting wires, it is sometimes possible to sling them on wire hooks some inches lower.

IBROXHILL ROCK GARDEN, BELLAHOUSTON PARK, GLASGOW.

WHEN the Glasgow Corporation acquired, in 1896, the western portion of the lands of Bellahouston, including the mansion-house and policies, extending in all to 178 acres, to form a public park for the south-western district of the city, it was quickly realised that the usefulness of the park would not be complete until the small estate of Ibroxhill, some 28 acres in extent, and so situated that it blocked what was obviously the natural entrance to the park from the city, was acquired also. Negotiations towards that end failed at that time, but some eight years later, when the property came into the market, the Corporation purchased the estate, and a new roadway was at once formed through the grounds to link up with those of the park. The public quickly realised the advantage, and the popularity of the park immensely increased.

Not infrequently, in the acquisition of suburban residential estates for public use, the authorities are faced with the question of the utilisation of the mansion-houses thereon. In some cases it has been found possible to utilise these successfully for such purposes as local museums, tea rooms and waiting rooms, though not infrequently they are not readily adaptable to these ends. In the case of Ibroxhill mansion, it was let for refreshment-rooms, but its proximity to shops and dwellings of the suburb militated against its success in that respect.

During the spring of 1913 dry rot was discovered in the woodwork of the house, and developed so rapidly that the occupation of the house was considered dangerous, so the tenants had to be compensated and cleared out as a matter of safety. As dry rot was present in every beam in the house from basement to ridge, the demolition of the mansion was decided upon.

A few years before this the old kitchen garden had been converted into a flower garden, and, having proved a popular resort, the Parks Committee agreed to the proposal that, when the mansion was demolished, the stones and debris might be utilised in the formation of a rock garden to add another feature in the park.

The work of demolishing the mansion was carried out by the parks staff during the late autumn and winter: and coincident therewith the outlines of the garden were laid out. The heavier stones were set aside, and the formation of the rock garden was carried out as circumstances permitted during 1914, a gardener who showed special aptitude for the work being put in charge of the arranging and planting of the garden, which was completed and opened to the public on July 1, 1915.

The photographs from which the illustrations in figs. 102, 103, 104 were reproduced were taken in June, 1917. The site of the old mansion house was prerainfall is not by any means a negligible quantity. In normal conditions the cultivation in the Glasgow locality of such ordinary plants as Aubrietias, Saxifrages, Sempervivums, Lithospermums, Pinks, Silenes, and Chieranthuses is very uncertain, as too frequently they collapse through excessive moisture in the soil during the winter, while in the case of more delicate or "miffy" subjects, such as Androsaces, it is hopeless to attempt their cultivation with the prospect of any degree of success.

The satisfactory growth of the plants in this garden has proved conclusively the fact well known to expert cultivators of Alpines—that good drainage is essential to success.

A list of the plants which have passed successfully through the past three winters in this garden would be too long to publish, but it may suffice to say that all the ordinary subjects flourish, and most of

FIG. 102.—IBROXHILL ROCK GARDEN, BELLAHOUSTON PARK, GLASGOW.

served, and the portico, which is of good design, retained as one of the entrances to the rock garden. Part of the kitchen court wall was left, also the stone-flagged floor of the kitchen, as shown in fig. 103.

Two walls of stone and turf were built to show what might be done in clothing an old unsightly wall and answer the frequent question, "What is a wall garden?" The foundation outlines of the building decided the main lines of the garden, and as no stones other than those from the old mansion were employed, the cost was only for labour and plants. It was not attempted to make the rocks the principal feature. The stones were only "the means to an end" in providing situations suitable for certain classes of plants, which in normal conditions do not thrive in a city where the soil is heavy and the atmospheric and climatic conditions are not of the purest and best, and where the the so-called "miffy" plants thrive satisfactorily. A variety of dwarf shrubs, and notably the newer Barberries, which were practically failures on the flat, are thriving amazingly on drained elevations of the rockery.

The same is true of the Broom family from the lowly Cytisus prostratus to those like Beanii, kewensis, Dallimorei, incarnatus, and the loftier albus, praecox, and Andreanus. Shrubby Veronicas and Ericas also do well, none of the plants having been killed by frost this spring, whereas those in the ordinary borders have suffered severely.

The interest displayed in this garden and the pleasure derived therefrom by the public has amply justified the Corporation in forming such an invaluable adjunct to this park, and may lead to the formation of similar gardens in other parks of the city. *Jas. Whitton, V.M.H.*

THE ROSARY

SEASONABLE HINTS.

I do not recall an earlier season for Roses than the present, and prospects look extremely promising. On June 4 I had several of the beautiful little Scotch Roses in bloom. Carmine Pillar was a blaze of colour, whilst the old pink China gave a wealth of its pretty pink flowers, and will continue to do so until the November frosts. Among the Chinas there can be no more useful kind than Comtesse du Cayla. Irish Elegance is in full bloom. One plant on an east wall is fully 8 feet high, and a bush in my Rose-walk is some 5 feet high and as much through. Neither of these plants has had any pruning this year; indeed many of the singles are best left unpruned.

Bedding and exhibition Roses should be thinned of superfluous growths. Crowded bushes only serve to give shelter to insect pests. Some plants well repay being tied out. This I do by driving pegs into the soil and attaching string to the shoot, then gently pulling it outwards and securing it to the peg. This is sometimes better than thinning out the shoots, and it encourages the development of basal growths. Soft basal growths that seem to be growing freely without showing bloom should be pinched back. They rob the flowering shoots of nourishment, and the pinching tends to harden them for another year.

Rambler Roses must not be overcrowded. If necessary, provide an extra pole or two, in order that some of the long growths may be secured to them, and thus prevent crowding on the original arch or pillar.

Many readers may have noticed a tendency to mildew on some Ramblers in past years. Drought is a frequent cause, and timely soakings with liquid manure and clear water alternately will help to ward off the disease. I have found it a good plan to make holes in the soil with a crowbar near the roots of Ramblers, but not near enough to damage the roots, and fill them with water or liquid manure. These holes may be left open for a time.

Liquid manure should be given now to such plants as need nourishment. Drills can be drawn each side of the plants, and the liquid poured in the trenches. When the drills are filled up, the soil, being loose, retains the moisture. In country districts where night-soil is available, this, applied in liquid form, surpasses all ordinary manures.

The soil of the Rose beds should be kept quite loose by frequent hoeing. A good tool for this purpose is the "Andyho." One end is arrow-shaped, the other wedge-shaped, and, being weighty, it opens the soil deeply.

Green fly is very troublesome this season, and needs much attention, but if timely spraying be carried out the pest should cause no concern. The leaf-curl saw fly has also been troublesome in some gardens. The foliage becomes twisted up in a spiral, and gradually perishes. Spraying with nicotine wash is the best remedy.

Where beetles and ground insects abound I would advise a dressing of "Tipulite." This is a fine soil fumigant, and quite harmless to plants.

Stocks for budding should be kept growing, and by the end of the month buds may be inserted. Standard Briar stocks should have side-growths reduced to three or four. Dwarf stocks should be slightly earthed up to keep the bark moist.

Polyantha Roses potted up in autumn should be plunged now in the beds intended for them. They will give a good display of bloom, and in October may be removed to cold frames ready for placing in the forcing house after applying a top-dressing.

Pot Roses that have finished flowering may be re-potted now. It is the best time to attend to Tea Roses, but the Hybrid Teas may wait until September. Personally, I do not favour too much re-potting. I have some pot Roses that have not been re-potted for four years, and they have done splendidly this season. Give the plants a top-dressing in autumn, and see that the drainage is perfect. *Experience.*

(See p. 241.)

CLAY CHALLENGE CUP FOR NEW ROSE.

THE Royal Horticultural Society offers the "Clay" Challenge Cup for a Rose not in commerce, possessing the true old Rose scent, for competition at the fortnightly meeting in the Drill Hall, Buckingham Gate, Westminster, in conjunction with the National Rose Society's meeting, on July 16. The conditions will be the same as those at the last Holland House Show in 1916; particulars can be obtained from the secretary of the Royal Horticultural Society, Vincent Square, Westminster.

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM GATTON PRINCESS.

ODONTOGLOSSUM QUEEN OF GATTON (triumphans × percultum), for which Sir Jeremiah Colman, Bart., received a First-class Certificate at the Chelsea Show, May, 1913, was pronounced to be probably the finest and most perfectly formed yellow-ground Odontoglossum raised up to that time, and it has never been surpassed in its class. Sir Jeremiah Colman, by crossing it with a pretty variety of O. eximium (ardentissimum × crispum) secured O. Gatton Princess, several forms of which have flowered and exhibited the dual capacity for variation noted in complex hybrids, one set having the yellow ground of O. triumphans and the other, as in the flower now sent, the white base of O. crispum, which enters into its composition twice, with three of O. Pescatorei, one of triumphans, and one of O. Harryanum. The flower is 3½ inches wide, each of the segments being 1 inch across and arranged perfectly flat. The colour is violet-mauve, with two or three thin, wavy, white lines across each segment and at the margin. The ovate lip has a dark purplish-red blotch in front of the crest and a band of thin red lines inside the margin.

APONOGETON DISTACHYUM.

THERE are few who are not admirers of the aquatic plant Aponogeton distachyum. Its fragrant, Hawthorn-like flowers, floating near the surface of the water, and continuing in succession for months, present an attraction which it is difficult to resist. The plant may be grown in any lake or pond, not too deep, and it may also be established in a small tank, or even in a tub. With a minimum of soil at the bottom, and from 10 or 12 inches to several feet of water, this Cape Hawthorn will flourish. Yet the plant has a grave defect, and the would-be possessor must be warned that it may prove a veritable old man of the sea in certain circumstances. In a pond containing Nymphaeas it becomes a pest, so rapidly does it spread, and it will eventually choke and destroy the Water Lilies, unless kept within bounds, which is a difficult thing to do. It must, indeed, be kept carefully out of any pond the waters of which drain into Nymphaea ponds, as the seeds of the Aponogeton may be carried down by the stream, and germinate in the pond so freely as eventually to lead to the destruction of the Nymphaeas. I know of a case where a pond containing a number of the finest of the hardy Nymphaeas was overrun by the Aponogeton from seeds floating down from some small pools higher up on the feeder. Several times the Aponogeton was carefully cleared out, but eventually the Water Lilies were choked, and the work had to be done all over again, the pools above being this time carefully cleared of the beautiful but all-pervasive Aponogeton. This is only one of several similar cases which have come under my notice. *S. Arnott.*

THE ALPINE GARDEN.

POTENTILLA AMBIGUA.

A WELL-KNOWN authority on Alpine flowers classes Potentilla ambigua with P. nitida and P. tonguei as the "real jewels" of the genus. The plant was, I think, more extensively grown a few years ago than it is now. It has apparently been elbowed out by novelties, many of which are less worth growing than this dainty Himalayan Cinquefoil. I have known the species for some thirty years, and have always welcomed it in its season as a bright little plant, excellent for the rock garden or even for planting in the crevices of a stone pathway. It delights to be jammed between stones in a sunny situation, and there its charmingly shaped leaves, with all the beauty of those of the other members of the Rosaceæ, and good-sized, bright yellow flowers, appeal to one's sense of dainty charm. It is not a difficult plant to grow, and, when happy, soon establishes itself among the stones. It does not like, however, to be jostled by stronger-growing subjects, and if these are allowed to overgrow it the chances are that Potentilla ambigua may disappear. It is often sold as P. dubia—a name which finds no place in the Kew *Hand List*. The species was figured in the *Botanical Magazine*, t. 4,613.

OXALIS ENNEAPHYLLA.

THE Patagonian and Falkland Islands Wood Sorrel is charming in its clustered leaflets of glaucous grey and pearly flowers. The blossoms are almost Convolvulus-like, and of a delicate pearly-white warmed and at the same time softened by a tinge of flesh pink. The plant thrives well in the corners of the rock garden. It does well planted in rich loam, and is also happy in loam and leaf soil. The rose-coloured form, named *rosea*, which we owe, I believe, to the search of Mr. Clarence Elliott, is a lovely plant, yet I think I prefer the type with its luminous white flowers, just redeemed from coldness by the tinge of pink. *S. Arnott.*

ON INCREASED FOOD PRODUCTION.

THE PRICES OF VEGETABLES.

WHEN allotments became so universal it was predicted that there would be a good supply of vegetables for all, even for those who were compelled to depend upon the greengrocer's shops. The reverse, however, appears to be the case, at all events in a south-western suburb of London where I reside. Cabbages and Cauliflowers are practically unobtainable, and for Lettuces 3d. and 4d. each is asked. What are termed greens are sold at 3d. per pound. These consist mainly of a thick stump weighing in most cases half a pound or so, with many of the leaves yellow and tough, the edible portion being very little. For Rhubarb 1s. 4d. a bundle is charged, and everything else is dear in proportion. All vegetables in the shops are in a rough and unattractive state. From the greengrocer's standpoint this state of affairs is owing firstly to the fact that the Army has taken so many men, and, secondly, to the difficulty attending railway transport. These facts may partially account for such an unsatisfactory condition of things, but one cannot help asking whether the shopkeeper, having, owing to allotments, a lesser demand for his goods, seeks to make up his loss by increasing the profits on what he does sell? At all events, it presses heavily on those unable to work an allotment. *W. T.*

CLIMBING HARICOT BEANS.

I AM one of those who have resolved on giving Climbing Haricot Beans a trial to dry for winter use. Ten months ago I made up my mind to do this. The trouble began when I sowed the seeds in boxes to the number of eight dozen. Out of this number I have got about thirty plants, good and bad. This result brought me to a conclusion similar to the experience expressed by C. Davis (p. 230), namely, that many of the seeds ripen too late to reach maturity before frost damages this tender crop. All the same, I meant to carry my design to a conclusion, and made two other sowings. The first sowing was made on May 12 and the seedlings planted out on June 1; the plants from the third sowing will soon be ready for setting out. Bamboo stakes are plentiful in our district, though somewhat dear. I was prepared for that. Horse Chestnut and Lime sticks last only one year; Bamboo canes will last four or more seasons, if tied in bundles and stored in a dry place. They are tidy, and take little room to store. The dried seeds are good, whatever the green pods may be. I have planted the Beans 2 feet apart, between Potatos, so if they fail there will be no waste of ground. *J. F.*

THE MARKET FRUIT GARDEN.

APPLE PROSPECTS.

THE outstanding feature of the present season is the disappointing set of fruit, following the very hopeful promise of the bloom. It is difficult to account for this failure, particularly in the case of Apples. They bloomed about a fortnight later than usual, and the weather at the time seemed to be all that could be desired for fertilisation. There was no frost, and the days were brilliantly sunny. There was only one heavy shower whilst the bloom was open. It is true that the wind was from an easterly direction, but it was never strong enough to make the air cool by day, though the temperature was rather low at night. Still, as it did not reach freezing point, no evil results were anticipated. Yet the set of fruit, considering the promising display of bloom, is one of the most disappointing I can remember. Only one possible reason can be suggested. Owing to the brightness of the weather the bloom was over much sooner than usual. Bees and other insects were very busy on it, but it is possible that they had not time to visit all the blossoms. However this may be, the fact remains that the greater part of the bloom dropped after the fall of the petals. Trees of many varieties that showed great promise are now quite bare of fruit, whilst others have only a sprinkling. The most satisfactory set of fruit is on Worcester Pearmain, a poor variety from the point of view of quality, but one of the most fruitful and profitable Apples for market culture. There is a fair crop on some old trees of Beauty of Bath, but the younger plantations have failed, and the same remark applies to Lord Grosvenor, Blenheim Pippin, and Allington Pippin. The reverse is the case with Mr. Gladstone, the older trees of which bore so heavily last year that their barrenness now can be understood. Cox's Orange Pippin, which gave great promise, will have only a very light crop. Charles Ross has a considerable crop, and there will be some fruit on Early Julyan, Domino, Bramley's Seedling, Bismarck, Golden Spire, Newton Wonder, and Royal Jubilee. Complete failure must be recorded in the case of Lane's Prince Albert, Duchess of

FIG. 101.—IRONHILL ROCK GARDEN, IN BELLAHOUSTON PARK, GLASGOW. THE WALL IN THE CENTRE IS PART OF THE OLD KITCHEN COURT.

(See p. 231.)

ONION MILDEW.

ONION MILDEW has made its appearance in parts of the country. As it is a disease which may seriously injure the plants and render the bulbs small, and prevent their keeping well, steps should be taken at once to hinder its spreading. This is the more important in that the demand for Onions later in the year is bound to be greater than in normal years, owing to the difficulties attending importation from abroad.

The mildew fungus may be controlled by dusting the plants early in the morning (whilst they are still damp with dew) with black sulphur or with flowers of sulphur and lime mixed in the proportion of two parts of flowers of sulphur to one of lime. Most dew falls during a still, clear night; in windy or cloudy weather dew may be practically absent. Spraying with Burgundy mixture (as advised for Potato blight) is also useful.

The mildew usually starts on autumn-sown Onions, and spreads from these by means of its spores to the spring-sown plants. The healthy plants should therefore be dusted or sprayed as well as the mildewed ones.

Oldenburg, Forge, Warner's King, and Lord Derby.

PLUMS AND BLACK CURRANTS.

The poor setting of Plums can be more easily understood. No more than 2° of frost was recorded whilst the bloom was open, but the weather was for the most part cold and dull, with a great deal of rain. In the circumstances we may congratulate ourselves on the sprinkling of most varieties secured, for reports from other districts are less favourable. Yet the set of fruit falls far short of the promise of bloom. Czar, the most regular bearer here, again has the heaviest crop. Rivers' Early Prolific carries a light crop, as does Monarch, and there is but little fruit on Pond's Seedling and Victoria. President and Black Diamond, which bloomed profusely, have failed completely. A plantation of Belle de Louvain, now grown to big trees, still fails to bear. As with most varieties of Apples, it is the older trees that are proving most fruitful.

Black Currants at one time promised well, but the fruit has since "run off" to a serious extent, possibly for want of moisture. Most of our Boskoop Giant bushes are getting past their prime, and the bud mite has made serious inroads, in spite of annual picking of the "big buds." Goddard's Monarch is so far more resistent to this pest, and now shows the best crop.

CATERPILLARS.

The plague of caterpillars is, I think, even worse than last year's. Spraying before the opening of the bloom killed thousands of the insects, and seemed to have practically cleared the trees. In the case of Plums the result remains satisfactory, most of the trees now looking healthy. This, I think, is because they were sprayed later than the Apples. Caterpillars of the winter moth and allied species evidently hatch out over a prolonged period, and early spraying, essential against aphides and Apple suckers (Psylla mali), does not affect the later batches. Spraying again, after the fall of the bloom, is generally needed with some varieties. This year the operation could not be completed before serious damage had been done in many cases. Moreover, the lateness of the blooming of Apples brought a difficulty where Black Currants are grown beneath the trees, these having got so forward as to make spraying with arsenate of lead a risky proceeding. No one seems to have established definitely how close up to gathering time one may safely use this very poisonous insecticide. Apart from the danger of poisoning the fruit, there is always the risk of spoiling its appearance by spotting, unless rain falls in some quantity before gathering time. Nicotine can be safely used, because its poisonous effect soon passes off, but this is much less effective than arsenate of lead when the caterpillars are half-grown.

Some Apple trees are completely stripped of leaves, and appear almost as in winter. On others, hundreds of fruitlets have been gnawed into and spoiled. Where spraying after the fall of the bloom has been possible it has had good results. We have used arsenate of lead alone in most cases, but with the addition of lime-sulphur at summer strength on varieties that are liable to scab disease.

There is no doubt that we are suffering very severely for the killing of birds by the hard winter of 1916-17. We shall be obliged to reconsider the question of grease-banding Apple trees next autumn, the caterpillar plague now having reached such a pitch that growers cannot afford to neglect any means of fighting it.

It is worth noting that certain varieties of Apples stand out this year as practically immune from caterpillars, though closely surrounded by infested trees. These are Charles Ross, Bramley's Seedling, Newton Wonder, Blenheim Pippin, and Royal Jubilee.—*Market Grower.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

PEAS.—Make final sowings of such varieties of Peas as Gladstone, Capt. Cuttle, Ne Plus Ultra, and Rearguard, thoroughly soaking the drills in dry weather before sowing the seeds thinly in well-prepared ground. Mulch the rows of these and midseason varieties, and give the plants liberal supplies of water and diluted liquid manure during long spells of hot weather. Whenever possible syringe all rows of Peas overhead in the evening with clear water, and well water the rows just as the first flowers open. If this practice is followed by mulching no further waterings will generally be needed. On porous soils late Peas should be grown in trenches containing plenty of manure. Do not place the seeds in contact with the manure, and gather every pod as soon as it is fit for use.

CELERY.—It cannot be too often pointed out how unwise it is to leave Celery plants crowded, either in the seed-pans or where they have been pricked out. Sturdy, well-rooted plants that are transferred to the trenches experience no ill effects from the removal. The trenches being ready, the first favourable opportunity should be taken of putting out the plants, but before the plants are disturbed they should be well watered, and watered again after they are set in the rows. Overhead waterings in the evenings of hot days will help the plants to grow rapidly and strongly. Soot dusted freely over and about the plants acts as a fertiliser, and serves as a deterrent to the Celery fly and slugs.

CELERIAC.—Small roots of Celeriac are of little value; the aim therefore should be to grow the plants as large as possible. Rough and very heavy ground is unsuited to this crop. In a dry season Celeriac requires to be watered as often as Celery, and should be given a mulching of short manure. The roots form a useful vegetable, and may be kept as late as May.

WATERING.—To maintain a succession of good vegetables it is necessary that water should be afforded the crops abundantly. In the case of dry soils much good may be done by applying mulchings of manure, short grass, or Hop-manure. Enough water should always be given at one time to soak the soil thoroughly. French Beans, Scarlet Runners, Peas and Cauliflowers will all be benefited by applications of liquid manure occasionally.

GENERAL WORK.—Potatos on warm borders are fit for use, and as they are lifted the ground should be cleaned, levelled, and made ready for another crop. Cauliflowers should be watched closely, as a few hours' exposure of the curds to full sunshine discolours them. The ground between the rows of the various crops should be kept stirred with the hoe whether weeds are present or not, and weeds in rows of seedling plants drawn out in good time. A few hours spent in surface hoeing now on bright days may save several days' labour later.

THE ORCHID HOUSES

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

CALANTHE.—Deciduous Calanthes of the Veitchii and vestita sections are now in various stages of growth, and plants that are unfolding their leaves and rooting freely may be given more water at the roots, increasing the supply gradually as the plants make further progress. Care must still be exercised in watering specimens that are not far advanced in growth. During all their stages the plants should be kept as near to the roof-glass as is convenient, in order that they may make stout pseudo-bulbs and strong flower-spikes. Plants of the evergreen species of Calanthes, such as C. masuca, C. veratrifolia, and C. Dominyi may be repotted as growth commences. These are free-growing, strong-rooted plants, and should be given rather large pots and a more retentive soil than many Orchids require. A suitable rooting medium consists of equal parts good fibrous yellow loam and chopped Osmunda-fibre, with a moderate quantity of leaf-mould and crushed crocks. Press the soil firmly and provide a space below the rim of the pot to permit of efficient watering, as the plants when well established require copious supplies of moisture at the roots.

LAELIA.—Plants of Laelia anceps and its varieties are growing freely, and should be afforded a liberal treatment in every respect. They should not be too densely shaded, but the blinds may be lowered in the morning when the sun is shining so brightly as to cause the foliage to become warm; they should be drawn up again early in the afternoon. The house should be ventilated freely during the hottest part of the day, but closed sufficiently early for the temperature to rise to about 90°, when the plants should be syringed overhead. Late in the evening the house should again be ventilated in order to lower the temperature to about 65° by morning, as the plants do best in a cool night atmosphere. Keep a sharp watch for slugs and woodlice, as these pests are very destructive to the young roots of this Orchid.

ZYGOPETALUM MACKAYI AND Z. CRINITUM.—These Orchids are rooting freely, and need copious supplies of water at the roots. The intermediate house will suit them at this season.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to Mrs. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

PLUMS.—Plum trees in late houses usually set their fruits in large clusters, and the bunches should be thinned freely, using a pair of Grape scissors. The shoots of cordons, and trees trained on trellises need to be constantly pinched to encourage the formation of fruit-buds for next year. All leaders and shoots required for the development of the trees should be trained to the wires to allow the light and air to enter the trees. The syringe may be used daily for some time to come; use soft water, or at least water free from lime sediments. Old trees carrying heavy crops will be benefited by a liberal dressing of decayed animal manure, but care must be taken not to overdo the mulching in the case of young trees, which would be likely to produce gross growth in consequence.

PEACHES AND NECTARINES.—Houses containing the leading mid-season varieties of Peaches and Nectarines should be freely ventilated, not only during the day, but a little through the night. This airing may retard the plants a little, but to produce Peaches and Nectarines of fine flavour the trees must have plenty of fresh air. Apply a mulch to trees on which the fruit is swelling, or feed the roots with weak liquid manure, but excessive feeding will cause the trees to make gross growth, which is useless for fruiting. Syringe the trees twice a day with rain-water, or red spider will be troublesome. Syringing with weak, clear soot-water does much towards keeping the foliage clean and healthy, serving both as a stimulant and an insecticide; the trees should be syringed with it once or twice a week. The final thinning of the fruits or disbudding should be attended to at once. When training the shoots in position, see that no more are retained than are needed. Water should be given in abundance if the borders require it, up to the time when the fruit commences to colour. The last soaking usually suffices until the fruits are gathered. At the ripening stage the house should be kept dry, with plenty of ventilation day and night. The fruits on trees in late houses will now be safe for the final thinning. A few extra may be left in case of some dropping, although trees in good condition do not usually cast their fruits in June. Regulate the shoots to prevent overcrowding and cut out the most vigorous growths. If the fruit is wanted very late in the season the house should be freely ventilated on all favourable occasions. Syringing, watering, and feeding should be carried out as advised for trees in successional houses. See that the borders do not lack moisture.

APRICOTS.—The final thinning of the fruits on late trees should be carried out without delay, and with a bold hand. Young trees growing in borders usually set their fruits very freely, and sooner or later they collapse if over-cropped. Let the borders have a thorough soaking of clear water with alternate doses of liquid manure. Old-established trees will respond to a mulching of half-rotten manure. Tie in the laterals where they are required for extension and pinch back other shoots to a few leaves. Keep the trees clean and healthy by syringing twice daily with soft water, and once a week with clear soot-water.

STRAWBERRIES.—Make preparations for the layering of plants for next year's forcing. We use 3-inch pots filled with rich loam, these being plunged between the rows of plants reserved for stock purposes. Old plants are practically useless for layering purposes. Bracken provides excellent material for making pegs to keep the runners in position. Spray the runners daily during bright weather until they are established.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

ANNUALS FOR POTS.—Many annuals are suitable for growing in pots for furnishing the conservatory or greenhouse during the summer and autumn. Although the plants are not particular in regard to soil, they will give far better results if a rich, substantial compost is provided for them. Among many which I have tried for this purpose, the following are the best: Asters, Browallia, Godetia, Clarkia, Lobelia tenuior, Larkspur, Nemesia, Statice sinuata, and Ten-week Stocks. Another sowing of Mignonette may be made now to raise plants for autumn flowering.

BOUVARDIA. If it is intended to grow Bouvardias in the open during the summer, the plants should be set in the beds forthwith. Plant them about 15 inches apart each way, and make the soil quite firm about the roots. Give one good watering after planting. Shade the plants during the hottest part of the day until they have recovered from the check caused by disturbing the roots. The shoots will need stopping on two or three occasions during the season.

CLIMBING ROSES. The young growths of Climbing Roses usually require very liberal thinning at this time of year. The work should be taken in hand in good time, or much of the energy of the trees will be wasted. Abundance of water will be required at the roots during hot weather; the foliage should also be washed every evening with the garden hose. Diluted farmyard drainings form an excellent stimulant for Roses; failing this, it will be necessary to use a concentrated fertiliser. Keep the trees free from aphis by regular fumigations.

VIOLETS. So far the weather has been unfavourable for the Violet plants which were put out in April. Unless they have been syringed each evening during the very hot weather experienced through May, red spider is almost sure to be present on the leaves. Frequent spraying with a suitable insecticide is the only remedy for this pest. The spraying should be done late in the evening, so that the specific may remain on the leaves as long as possible. Work the hoe freely amongst the plants, and remove all runners as they appear. A light dusting with well-seasoned soot previous to hoeing will have a stimulating effect on the plants, besides acting as a deterrent to insect pests.

CLERODENDRON FALLAX.—Allow this plant ample room, as crowding causes the loss of some of the lower leaves. Old plants which were re-potted in the spring should be liberally fed with stimulants when they are well rooted. These plants should carry from three to six large heads of flowers. Young plants which have been raised from seed this season should be potted on as their requirements demand. A compost formed of good fibrous loam, leaf soil, old Mushroom-bed manure, wood ashes, and coarse sand is suitable. Keep the plants growing in a warm, moist atmosphere, and spray them two or three times a day with rain-water. If red spider attacks the under-sides of the leaves syringe the affected parts with an insecticide.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

GENERAL WORK.—Keep the hoe at work freely at this season to destroy both suckers and weeds, and make the soil more receptive of moisture during rainfall. Even when a mulching is applied it will do good to use the hoe for stirring it; this will assist in pulverising the mulch and cause it to be gradually worked into the surface soil. After such a stirring it will be well to take the first opportunity to give the roots of the trees a good watering, and especially in the case of newly planted trees. Let these latter be also syringed towards the evening, and it will be doubly beneficial to trees planted against walls. Endeavour to ensure good growth on newly planted trees well in advance of, and not so much in, the later months, when the wood will be ripening. There is plenty of work needing attention in the way of pinching, stopping, and regulating the growths. It is far better to do this work in advance than to allow some shoots to get the upper hand at the expense of others. I advocate a free use of the thumb and finger for pinching, not only of shoots but also of surplus fruit that can well be spared, or advance of any ultimate thinning. In the case of dessert Cherries the final thinning has to be done much earlier than with any other fruit, but this operation needs careful attention. If these Cherries are predisposed to turn yellow at the stoning period it is not safe to thin too freely or too early. The nets should be got ready for protecting dessert Cherries from birds, which may cause trouble as soon as the fruits show the least tendency to change colour. In some instances I advise fairly early netting of the trees; for example, where the Cherries fail to stone very badly, which may occur where the trees on walls are exposed to hot sunshine. Early netting will aid in keeping the trees somewhat cooler by giving them slight protection from the sun's rays.

INSECT PESTS. Insect pests are very troublesome in certain districts, and causing much damage to fruit trees. As soon as we were threatened with trouble in this respect I had recourse to spraying with Katakilla specific, and found it most effective. American blight has begun to spread during the past fortnight, but after a strong dressing of winter wash I did not expect it would prove troublesome. A strong dose now of paraffin soft-soap is a good remedy where it can be applied with a stiff painter's brush directly on the affected parts. If this is not practicable then paraffin emulsion should be sprayed on the trees. I notice that Gooseberries are being attacked by red spider. For this pest I shall use lime-sulphur spray, but not strong enough to injure the foliage. Another good and safe remedy is fairly strong soot-water.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

MYOSOTIS. There are several distinct kinds of Myosotis (Forget-me-not) of great beauty, some of which propagate themselves freely from seed. Myosotis sylvatica and its white form are here established on grass. Some, including M. dissitiflora and the variety Ruth Fischer, need to be rooted from cuttings annually, but the latter variety makes little progress here, and cannot compete with other well known kinds. All should be propagated now in order to have good flowering plants for autumn planting.

FRITILLARIA. Where Fritillarias and later spring flowering bulbs and tubers are to be transplanted, they should be lifted out of the ground as soon as the foliage is yellow, and may either be planted at once or kept in a cool place until October or November. The beautiful varieties of Anemone apennina and the double form of A. nemorosa should also be lifted, divided, and replanted now. They are beautiful in masses, and succeed anywhere, either in the open or in partial shade.

PINKS.—The pretty florist forms of Pinks, as distinct from border kinds, such as Her Majesty, which are best increased in autumn, should be propagated now for transplanting in autumn. The "pipings" are drawn out of the growing flowerless shoots, and require no further preparation. They strike root freely under a variety of conditions. Some growers dibble them into prepared soil at the base of a fruit wall, and others under Gooseberry bushes. An ordinary hand light or large bell glass, with the glass blurred by sand sprinkled on the inner side while the glass is wet, gives least trouble, once the pipings have been inserted. A very large number can be rooted in a small space, an inch apart being wide enough to set them.

DAHLIA.—The planting of spring-struck Dahlia plants need no longer be delayed. There is such a variety of forms that one has only to decide which of them are most suitable for one's requirements. I find that the tubers of new varieties, which are moved into larger pots immediately they are received from the nursery, keep much better during winter when they are sunk into the ground, pot and all. When very fine blooms are desired the old plan of planting in pits filled with a rich compost is excellent. For ordinary decorative purposes a fairly fertile soil, with the plants not crowded, is all that is necessary.

THE APIARY.

By CHLORIS

SOURCE OF HONEY.—Honey itself is not gathered—it is the nectar of the flowers, which the bees collect and carry in their honey-sac to be assimilated and regurgitated in the form of honey. The source of the honey may be fairly well and accurately recognised by its colour and flavour. The flowers often exude nectar similar in colour to the bloom, but when it candies it always becomes lighter. White Clover honey is always very light, that from Lime greenish-yellow, while honey from Sainfoin is very yellow, and Heather honey varies from orange to reddish-purple. The weather and time of the year also influence the flavour; when it is warm and sunny the flavour is very much stronger than when it is cool. Clover honey is very liquid, and that from Heather is so thick that it has to be crushed out of the comb in a press. Its flavour is very pronounced.

PREVENTING SWARMING.—This is often achieved by the following method. Instead of having shallow frames in the super, use the brood frames. Take the brood frames out one at a time on a very warm day, and, as the frames are lifted out, give them a sharp shake to dislodge all the bees. Carefully examine each frame when free of bees to see if any queen cells have been started. This done, place each frame in a similar position in an empty brood chamber. Having completed the examination of all the frames, and being certain that the queen herself is in the original brood-chamber, proceed to fill it with frames fitted with full sheets of foundation. Place over it a sheet of queen-excluder zinc, and over this the brood chamber containing all the brood. Wrap up with good quilts, and as the brood hatches the cells will be filled with honey. Occasionally a few drones are hatched, and as these cannot pass through the queen excluder zinc because of their bulkiness, a corner of the quilt may be occasionally raised to permit of their escape. This method gives the queen plenty of egg-laying space, and is generally successful in preventing swarming.

USING THE SMOKER. Too often the amateur uses the smoker too much and sometimes among the frames. This is incorrect. First get the smoker going, using as fuel unglazed brown paper, corrugated brown paper, old corduroy cloth, dry, rotten wood, or anything that will easily smoulder and give off a good supply of smoke. Lift one corner of the quilt and blow a little smoke under it. When the quilt is being raised puff across the frames, not among them, and use as little smoke as possible—just enough to keep the bees under full control. When handling frames commence with the outside one and remove that first; after sliding back the division board, shake off the bees and place it on end outside the hives. This will give plenty of room to handle the other frames without fear of crushing the bees or killing the queen.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER** 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS**, **41, Wellington Street Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, JUNE 18—
Roy. Hort. Soc.'s Cons. meet. Hort. Club Com. meets. Farmers' Club, 4 p.m.

WEDNESDAY, JUNE 19—
Lecture on Potato Growing, at Caxton Hall, Westminster, by W. Cuthbertson, 3 p.m.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 59.4.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, June 13, 10 a.m.: Bar. 30.2; temp. 66.0°. Weather—Cloudy.

Robert Hooper Pearson.

It is with the deepest regret that we record the death, early on the morning of Tuesday last, June 11, of Mr. R. Hooper Pearson, Managing Editor of the *Gardeners' Chronicle*. Mr. Hooper Pearson's death, which was due to anæmia, will be mourned not only by all his colleagues on the staff of that journal, but by a large circle of friends. For it was given to few men to form and to hold friendships as it was to Mr. Pearson.

The secret of his character and influence was a sane steadfastness—as one who "looks on tempests and is never shaken." Combined with the serene and sure judgment which made him the fairest of colleagues and the most sympathetic of friends, was a broad sympathy with all worthy things. Devoted to his duties as assistant and later as Managing Editor, which duties he followed without intermission for upwards of a quarter of a century, Mr. Pearson was no less concerned with the interests of horticulture. To these objects he devoted his life with a singleness of purpose which won the admiration of all who knew him. His alertness of mind and vast fund of experience were given without stint in the performance of his daily task, and it is a high and great tribute to say that never did his attention to detail cause him to lose sight of the large and permanent interest of horticulture. A slip, a misprint, or small error in the pages of this journal caused him more chagrin than a personal disappointment, and it is to his watchful vigilance that the journal owes its immunity from any undue number of such errors as are almost inevitable under modern conditions of publication.

With the steadfastness of character which made him so sure an adviser, Mr. Pearson possessed to a remarkable degree the gift of loyalty to friends and colleagues. In the trying intercourse of common work the present writer can remember no occasion on which perfect harmony did not exist between Mr. Pearson and the members of his staff. If he reproved, the reproof was manifestly deserved; if he praised, the praise was well earned. Nor was there any hardness in his nature to mar the just temper of his mind. Fond of the amenities of life, he was fonder yet of its duties, and discharged them faithfully and without any sparing of himself.

It is but a little more than a year ago that we published a brief account of Mr. Hooper Pearson's 25 years' service of the *Gardeners' Chronicle*. In that record testimony is given to the feelings with which his colleagues regarded him. These feelings of admiration, regard, and affection remain and will endure, for now that he has passed away we, like all his friends, recognise that he not only possessed great qualities, but that he used them worthily. He laboured unceasingly and disinterestedly at the task to which he devoted his life, and in accomplishing that task he helped us all to discharge our own.

Mr. Pearson was born on July 18, 1866, at Brewood, in Staffordshire; his father was proprietor of the local High School, and here the son received his education. His gardening proclivities were pronounced even at an early age, and his father apprenticed him in the neighbouring gardens of Keele Hall, under Mr. John Wallis. After serving his apprenticeship, he applied for entrance to Kew Gardens as a "young gardener," and was successful in becoming a member of the Kew staff. After his two years' training at Kew, where he rose to the position of sub-foreman, he sought further experience in the Marquis of Bute's garden at Cardiff Castle, and he was always appreciative of the excellent training he received under the late Mr. Andrew Pettigrew. He then went to Patshull Hall, Staffordshire, but after a short stay there he was offered a position on the *Gardeners' Chronicle* by the then Editor, the late Dr. Masters.

Mr. Pearson was keenly interested in every aspect of horticulture, and held many offices in various societies. He was Hon. Secretary of the Horticultural Club, and during his term of office the membership increased from about fifty to some two hundred. As Press Secretary of the International Horticultural Exhibition in 1912 he contributed largely to its success. He was a member both of the Scientific and of the Floral Committees of the Royal Horticultural Society: an active supporter of gardening charities, he held a position on the executive of the Royal Gardeners' Orphan Fund for many years, and took a real interest in the children who were supported out of the funds. He was instrumental in helping to found the British Gardeners' Association, in the hope that it might prove of benefit to members of the profession. During the year 1911 he held the office of President of the Kew Guild, an association which always commanded his warmest sympathy.

As an author, his best-known work is *The Book of Garden Pests*, but his name became famous through the popular series of books known as *Present Day Gardening* series, edited by him, and written by authors chosen by him as specialists on the different subjects. At the time of his death he was engaged on several horticultural works, but during the past year his strength was scarcely equal to any undertaking of a literary nature.

He married in September, 1893, Miss Jeannie Evans, daughter of James Evans, of Llangattock, Lingoed, Abergavenny. He has one child, a daughter; both his wife and daughter survive him, and will have the sincere sympathy of all in their bereavement. The funeral will take place at Putney Vale Cemetery to-day (Saturday), at 12.30 p.m., and will be preceded by a service at St. Anne's Church, Wandsworth, at 11.45 a.m.

FLOWERS IN SEASON.—Messrs. R. WALLACE AND CO., LTD., have sent us a box of Irises of the June-flowering section, classed as late-flowering bearded Irises. These beautiful flowers are very popular garden plants, and grow well in nearly all kinds of soil. The section embraces the German Irises, I. squalens, I. plicata, I. neglecta, I. amoena, and other species, but the hybrids are now so complex in their parentage that it is difficult to keep them distinct. Of the very large number of varieties sent, the following specially appeal to us.—Lady Foster, a very large flower, with pale blue standards and light, bluish-violet falls; Isoline, with lilac-pink standards and purplish-old-rose falls; Alcazar, light bluish-violet standards and deep purple falls; Troost, a rosy-purple variety with paler-coloured falls veined with violet; Lohengrin, a large flower of the pallida section, of a beautiful rose shade; Ma Mie, white, tinged with blue at the margins; Hiawatha, with pale lavender standards and royal purple-blue falls, with a lighter tone at the edges; and Oriflamme, one of the largest varieties, the large standards coloured bright blue, with falls of dark purple.

DAHLIA TUBERS AS FOOD.—Monsieur BUYSMAN, Curator of the experimental Botanic Garden at Lawang, Java, writes to us on the subject of Dahlia tubers, which he observes are edible when cooked. He states that in Mexico they are used everywhere as food.

LECTURE ON POTATO-GROWING.—A lecture will be delivered at the Caxton Hall, Westminster, London, on the 19th inst., at 3 p.m., by Mr. W. CUTHBERTSON, V.M.H., on "Potato Growing: Autumn Work in Lifting and Storing." The Right Hon. R. E. PROTHERO will occupy the chair. Admission, so far as the seating accommodation will permit, will be by ticket to be obtained by written application, enclosing a stamped and addressed envelope to the Secretary, R.H.S., Vincent Square, Westminster, London, S.W. 1. Fellows' tickets will not admit, as it is necessary to know beforehand the amount of seating required. Printed copies of the lecture, with illustrations, will be distributed at the end of the meeting.

GARDENERS' RATIONS.—The Ministry of Food has decided that a gardener mainly engaged in the production of food is eligible for supplementary rations, as follows:—He must either be employed in the production of food on at least one acre of land; or be engaged throughout the whole working day on the production of food. All other gardeners are graded "B."

PLANT IMMIGRANTS.—Among plants and seeds reported * as introduced recently into the United States is a dwarf Peach procured by the Rev. GEORGE CAMPBELL in Southern China. The Peach is treated as a pot plant in that country, and is said to come true from seed. The Rev. G. CAMPBELL reports that one small tree 15 inches high, with a stem no larger than a lead pencil, ripened five good-sized, edible, clingstone Peaches. The behaviour of the plant out-of-doors at Chico suggests that it may be of value in the production of a dwarf race of Peaches.

MAIZE SEED.—A word of warning is necessary to those who may intend to endeavour to save seed of early-ripening varieties of Sweet Corn. Maize is one of the plants which must be cross-pollinated if the vigour of the stock is to be maintained, and therefore seed should not be saved for sowing purposes unless raised from cross-pollinated plants. Cross-pollination is, however, easily effected. The male blooms are removed from the plant which is to act as seed-bearer. The female inflorescence is covered, and as soon as the tassels (styles and stigmas) are well developed a male inflorescence with ripe pollen is drawn like a brush over the tassels and the female flowers again covered. The pollina-

* *Plant Immigrants*, No. 133, May, 1917.

tion should be repeated on the following day, and the operation should be carried out in bright, sunny weather.

ANOPHELINE MOSQUITOS.—In connection with possible risks of malaria being acquired in this country, the Local Government Board is anxious to collect as much information as possible regarding the prevalence and distribution of anopheline mosquitos in various parts of the country. Naturalists and field botanists could give much valuable help in the matter by keeping notes and records of any adult insects which they may meet with during natural history searches, and also of the detection of anopheline larvae. In making records the following are important:—Adults: Date: hour of collection: place (if in a building specify its nature): condition of weather and temperature: whether few or abundant. Larvae: Date; hour of collection; locality; nature of collection of water (natural or artificial); nature of breeding-place (shady pools, open collections of water, presence or absence of weed, fish, etc.).

SEED IMPORTS TO AMERICA.—A large decrease in the seed exports from England, to the United States for the last year, is indicated by figures recently issued by the Department of Commerce. The amount of the seeds exported is given at 1,119,114 lbs. for 1917, as compared with 4,568,203 lbs. for 1916. The value is given at 136,903 dollars for 1317, and 384,947 dollars for 1916.

DESTROYING TREE STUMPS WITH ACIDS.—It is generally believed that tree stumps can be got rid of, or at least rotted so that they will burn freely, by treating them with strong acid, such as sulphuric or nitric acid, and waiting a few weeks. In order to test the matter, a series of experiments was undertaken by Mr. F. B. GUTHRIE, chemist, in 1915, and deep auger holes were bored in selected stumps of tough timbers, some green and some dry. Quantities of the chemicals named, separately and together in varying proportions, were poured into different stumps. The results were noted regularly for six months, at the end of which time an examination showed that in the case of both green and dry stumps the acid had no appreciable effect. The average cost per stump worked out at 1s. 9d., which included labour at the rate of 7s. per day; it is an open question whether men could be found who would use two such dangerous acids at that figure. Saltpetre has also been said to be useful in preparing dead timber for burning off, but numerous private experiments go to disprove the theory. *Queensland Agricultural Journal.*

AN INDIAN "PRAYING PALM."—We learn from *Nature* that another Indian "miracle" has been explained by scientific investigation. The *Pioneer Mail* of January 11 reports a lecture by Sir J. C. BOSE on "The Praying Palm Tree" of Faridpur. While the temple bells call the people to evening prayer, this tree has recently been seen to bow down in prostration, and to erect its head on the following morning. Large numbers of pilgrims have been attracted to the place, and offerings to the tree are said to have been the means of effecting marvellous cures. Sir J. C. BOSE first procured photographs which proved the phenomenon to be real. The next step was to devise a special apparatus to record continuously the movement of the tree by day and night. The records showed that it fell with the rise of temperature and rose with the fall. The records obtained in the case of other trees brought out the fact that all the trees are moving, each movement being due to changes in their environment.

THE FLY PEST.—The British Museum recommends the use of baited wires as a means of keeping down the house fly. The mixture for the bait consists of castor oil 4 liquid oz., crushed resin 9½oz.; or linseed oil 4 liquid oz., crushed resin 7½oz. It is recommended to heat the oil and then stir in the resin. The mixture is painted on wires about a yard in length, leaving a handhold at one end unpainted, and making a hook at the other for hanging the wire vertically. When covered with flies the wire is passed through a flame to clear it of the used mixture and dead flies. Afterwards fresh mixture is heated and the wires painted as before.

A NATIONAL FLOWER FOR MASSACHUSETTS.—The school children of Massachusetts, U.S.A., have indicated their choice of Epigæa repens (the trailing Arbutus) as the State floral emblem. This flower received 107,617 votes, or 49,409 more than its nearest rival, the Water Lily. The number of children who voted was 241,864. The canvass was made under the direction of the State Board of Education of the Legislative Committee on Agriculture. Although the committee is not formally bound to abide by the decision of the children, it is probable that it will do so, and report to the Legislature a bill designating the trailing Arbutus as the official floral emblem of the State.

THE LATE ROBERT HOOPER PEARSON.

DANDELIONS IN LAWNS.—A writer in an American paper states that if Dandelions are dug by hand and a small pinch of White Clover seed placed where the weeds have been removed, the seed will grow and assist in crowding out the Dandelions. White Clover has been found one of the best lawn seeds for this purpose, as it may be scattered on top of old grass to thicken the stand. Yet it must be remembered that for tennis lawns Clover is almost as undesirable as Dandelions.

POISON GAS AND HORTICULTURE.—It does not require much imaginative foresight to predict that the use of poison gas in the present war may be followed by an application of the practice beneficent to horticulture. Our reasons for suggesting that this will prove to be the case are simple. Poisons are, to some extent, differential in their action, and hence it should not be impossible to discover a poison which, whilst harmless to vegetation, is deadly to animal life. Further, the leaves of most plants close their stomata at night, and when foliage is in that condition it is not easily injured. Horticulture has already had experience with poison gas, in the form of hydrocyanic acid, vaporised sulphur, and nicotine, and also in the form of carbon-bisulphide and other chemicals used for soil sterilisation purposes. Hence the principle is not new, but what is new is the fact that poison gas officers have, from their tragic war experience learned to manipulate and control the poisons in an extraordinarily accurate way. So much so that we believe they can, like CANUTE, command the gaseous sea they liberate, and, unlike that potentate, ensure that their commands are obeyed. By making use of suitable conditions of weather it is stated that the distribution of gas may be controlled within very narrow limits. Hence instead of the present-day laborious method of syringing, the future may see our orchards equipped with poison gas cylinders, and the insect pests of the orchards destroyed like the hosts of SENNACHERIB, and by no dissimilar means. Whether the problem of soil sterilisation will, in the future, be solved in like manner we lack the hardihood to predict, but there would seem to be no *a priori* reason why it should not. We believe that some experiments along these lines have already been carried out, and also that others are in progress. Should they prove successful it will once again have been shown that "there is a soul of goodness in things evil."

WAR ITEM. Pte. H. L. DOUGLASS, R.A.M.C., London Field Ambulance, has been missing since March 28, and is now believed to be a prisoner of war in Germany. Prior to enlistment in August, 1915, he was employed as foreman at Heacham Hall Gardens, Norfolk.

PUBLICATIONS RECEIVED.—*The Carnation Year Book, 1918.* Edited by J. S. Brunton, British Carnation Society. (T. A. Weston, Floradale, St. John's Road, Orpington.) Price 1s. 6d., post free.—*Allotments far All.* By Gerald W. Butcher. (London: Geo. Allen & Unwin, Ltd.) 2s. net.

RHODODENDRON SPINULIFERUM.

SOME Rhododendrons differ widely from what is regarded as the normal type of the genus, and R. spinuliferum (see fig. 105) is one of the most divergent species. Specimens were shown in flower by Mr. Reuthe at a recent meeting of the R.H.S., and many, on seeing them for the first time, expressed doubt as to the plant being a Rhododendron. The allied genus Erica, and particularly the South African species, offer an even wider range of variation than that genus. R. spinuliferum may never obtain a First class Certificate as a garden plant, and yet it has claims to horticultural favour in the bright cinnabar-red colour of its tubular flowers as well as its unlikeness to garden Rhododendrons. The species was introduced into cultivation in 1907 by Messrs. Vilmorin, Andrieux and Co., and specimens flowered at Les Barres in 1910. It has been grown for some years at Kew, where, however, it requires the protection of a greenhouse or frame. According to Forrest the species grows in shady thickets on the hills in Yunnan at an altitude of 6,000-8,000 feet. Mr. Millais describes it as a shrub of tall, thin habit up to 6 feet high, making slender shoots of 12 inches or more annually. In Mr. J. C. Williams' garden at Caerhays this Rhododendron is grown in shade against a wall, where it does well. In the form of its flowers R. spinuliferum resembles R. Keysii, a Bhutan species, of which there are big bushes in South Cornwall, Ireland, and other parts of Great Britain, but the habit and leaves are very unlike, and the flowers of R. Keysii are borne in axillary clusters on the old wood, whereas in R. spinuliferum they are in terminal clusters, usually four in a cluster.

FIG. 105.—FLOWERING SHOOT OF RHODODENDRON SPINULIFERUM.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

IRISES AND DISEASE.—Even at the risk of incurring the title of "faddist," which Mr. Watson bestows on those who transplant rhizomatous Irises in summer, I cannot let his remarks, on p. 233, pass unchallenged. It has probably been my lot to plant and replant as many kinds of Irises in the last ten or fifteen years as most gardeners deal with in a much longer period, and I doubt very much whether it is really "so utterly opposed to nature to dig up rhizomatous Irises when in full leaf" as Mr. Watson appears to imagine. If he will dig up a plant that is just going out of flower he will find that the roots attached to the main axis which ends in the flowering stem are brown and withering. Obviously they have done their work in nourishing the stems and the flowers. It is to the lateral growths that we must look for flowers in the following year, and here he will find that root-growth is beginning. There may be young, unbranched fibres a few inches in length, and, besides, there are sure to be a number of points of new roots just pushing out from the rhizome. Surely, then, this is the moment at which transplantation may be carried out without detriment to the plant. Mr. Watson does not tell us when he would transplant such Irises, but presumably he would do it in the autumn or in the early spring. In the former case, root-growth has ceased for the year, and the plants lie in the ground through the winter without taking hold of it, and are often actually lifted out of the soil by frost and thaw, while in the latter case the flowers for the coming season are either entirely sacrificed or at least stunted. I wish Mr. Watson could have seen my garden a week or two ago. There were many beds of Irises in full flower, although all the plants in them were transplanted in June, July and August last year. On the other hand, there were a few in which the Irises had had to be planted later. In these the plants were stunted and the flower-stems few. For the disease from which apparently the Kew collection is suffering there is a very simple remedy, namely, superphosphate of lime. I must confess that my garden is never entirely free from traces of this disease, but, on the other hand, I think I can truthfully say that it has never yet carried off all my plants of any variety or species. I seem to recollect that I was once told that, when the disease first appeared at Kew, the beds were dressed with lime. If this is so, it is hardly surprising that no cure was effected, for once the bacillus that does the harm is present, it is an acid reagent, such as superphosphate, and not the neutralising lime, that is required to destroy it. When leaves turn yellow and rhizomes rot, usually at the neck, level with the ground, the diseased portions should be pulled or cut out and superphosphate sprinkled liberally all round and watered in. Within the narrow limits of my garden I am unable to give my plants fresh soil as often as I should like to do, but it has become my practice always to dress the surface fairly liberally with superphosphate whenever Irises are being transplanted, and so far, at any rate, my collection has not suffered to any appreciable extent. *W. R. Dykes, Charterhouse, Godalming.*

THE COLOURS OF FLOWERS.—In the very interesting note on p. 239, Mr. E. H. Jenkins refers to the influence that the soil exercises on the colour of the flowers grown therein. In addition to this the atmosphere also plays a very prominent part, as may be seen by the colour of flowers grown in different conditions. Not only are the tints of many blossoms deepened by exposure to a clear, pure air, but also the leaves of those with bright-coloured foliage. This was brought markedly home to me some years ago, when spending a short holiday on the southern slope of the Sussex Downs. I was surprised at the colour of the leaves of tricolor Pelargoniums, then in the height of their popularity. I flattered myself that I know most of the popular varieties, but so rich was their colouring that I had in some instances to confess myself beaten. All the outdoor flowers were very bright, as also were the leaves of Acalyphas, Crotons, and other fine foliage plants grown under glass. It was this same atmosphere which enabled Messrs. Balchin, when at Hassocks, to grow such splendidly coloured hard-wooded plants, and especially the charming blue Leschenaultea biloba major. The collector of plants in Alpine regions is often disappointed in the colour of the flowers of the plants when grown under cultivation. *W. T.*

PROTECTING STRAWBERRIES.—The plan of cutting straw for the protection of Strawberries against the soiling of the fruits, mentioned by Mr. J. A. Pace on p. 235, is new to me, and evidently an effective and good one. Straw, however, is out of the question at the present time in many gardens. Years ago, when I had to protect 20 rods or more annually, I used nothing except lawn mowings. These were always plentiful just when the flower-trusses were showing or beginning to open, and as soon as the mowing was completed the grass was wheeled to the Strawberry plots. This being early in the season the grass was free from seeds, and the mowings short because done by the machine. The grass was carried down the rows in baskets and laid over the ground to a depth of 2 inches or 3 inches. After a few days' sunshine the grass got compressed or shrunk to half an inch, or less after rain, and the grass blades being interlaced they resembled a piece of coarse cloth, on which the berries lay down

as they became heavy, and remained perfectly clean when ripe. This method of strawing, if I may use the term, kept down weeds and prevented any trouble from slugs, except to a small extent in unusually wet seasons. I have known of a case where peat moss litter, used for the above purpose, and for feeding the plants, harboured snake millipedes (Blanjulus) till they became a veritable pest on account of their numbers. *J. F.*

SOCIETIES.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

MAY 9.—The annual meeting was held on this date, the Rev. J. Crombleholme presiding. The report and balance-sheet were adopted. R. Ashworth, Esq., was re-elected president. The vice-presidents, officials, and committee were re-elected, with the addition of Messrs. Wm. Pickup, E. Rogers and S. Davenport.

The prizes were presented to the successful exhibitors as follows:—

Gold Medal, presented by Mr. J. J. Bolton, to the Rev. J. CROMBLEHOLME (Gardener's Prize to Mr. E. Marshall).

Silver-gilt Medal, presented by Mr. Bolton, to S. GRATRIX, Esq. (Gardener's Prize to Mr. J. Howes).

Botanic Society of Manchester's Gold Medal, to Mr. C. BRANCH.

A. P. Handley's Prizes, to Messrs. E. ROGERS and S. DAVENPORT.

Messrs. Charlesworth's Objet d'Art, to S. GRATRIX, Esq. (Gardener's Prize to Mr. J. Howes).

Messrs. Cypher's Gold Medal, to R. ASHWORTH, Esq. (Gardener's Prize to Mr. S. Davenport).

Dr. Craven Moore's Silver Cup, to R. ASHWORTH, Esq. (Gardener's Prize to Mr. Davenport).

A. P. Hommer's Silver Cup, to R. ASHWORTH, Esq. (Gardener's Prize to Mr. Davenport).

Messrs. McBean's Silver Trophy, to R. ASHWORTH, Esq. (Gardener's Prize to Mr. Davenport).

Mr. P. South's Prizes, to Messrs. S. DAVENPORT, C. BRANCH, and J. LUPTON.

Committee present: Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, D. A. Cowan, J. C. Cowan, J. Cypher, A. G. Ellwood, A. R. Handley, J. Howes, A. Keeling, J. Lupton, D. McLeod, W. Shackleton, and H. Arthur (*secretary*).

AWARDS.

FIRST-CLASS CERTIFICATES.

Odontioglossum crispum Briton, a full, round, white flower, with a deep blotch on the lip, from Mrs. S. GRATRIX.

O. c. xanthotes Conyngham, a well-shaped flower with lemon-yellow markings, from Dr. CRAVEN MOORE.

O. Peeetorei Monica (Lindenii × Charlesworthii), from Col. Sir J. RUTHERFORD, Bart.

AWARDS OF MERIT.

Odontioda Harlequin, a fairly large flower, with large blotches of reddish brown on the segments, from S. GRATRIX, Esq.

Obituary.

JOSEPH TAILBY.—*Horticulture*, U.S.A., announces the death of Mr. Joseph Tailby, florist, at his home in Wellesley, U.S.A. Mr. Tailby was a native of Leicestershire, and settled in America in 1864. After spending two years in Hoboken, N.J., in New York and Framingham, he settled in Wellesley and established a florist's business. He was a successful hybridist, and raised, amongst other things, a fine Cucumber, named Tailby's Hybrid, and Carnation Grace Wilder, this being a variety without a peer in its day and the first really good commercial Carnation of its colour. In the same year Mr. Tailby introduced Fred Johnson, a light red Carnation, and Princess Louise, rose-pink, and both of these had considerable local celebrity. More recently he produced a new race of hybrid yellow Callas.

CROPS AND STOCK ON THE HOME FARM.

MACHINERY.

ALTHOUGH so much extra land has lately come under arable cultivation, the work is well in hand, thanks in great measure to the employment of German prisoners of war. I have nothing but good to say for these men, both for manual and for horse labour. At first they were strange to our methods of procedure, but they quickly adapted themselves to circumstances, and now they make very good ploughmen.

They are also excellent hoers, assiduous in their work, and quick to learn. They planted out most carefully 70,000 onions that were raised in boxes. Some few farmers had at first an objection to their employment, but this feeling quickly gave way to wiser counsels, and now the supply in this district is inadequate to the demand. The Government has certainly equipped them with excellent material, ploughs, harrows, rollers, drills, and harvest appliances.

The continued scarcity of skilled workmen—carters especially—will induce farmers to employ more machinery. Motor vehicles are excellent labour-saving appliances. In suitable sites—flat fields and light soils—no trouble need be experienced in ploughing five acres per day. As cultivators, too, they render excellent work at a small cost. In grass and corn cutting they are very useful, and easy to learn to drive. The heavier types are road haulers, and can be employed to thresh corn. Where the land is stiff and heavy a special type for such a purpose should be selected. Do not expect, however, to plough too many furrows at once. If three furrows are well done it should be sufficient.

RUST ON WHEAT.

Certain fields of Wheat which looked promising a short time ago are now attacked by "rust." *Puccinia graminis*. Some farmers hold that rust is transmitted from one Wheat crop to another. This may be so under certain conditions, but in one crop I have in mind Wheat is following a Sainfoin ley which had been down ten years.

My own experience leads me to believe that excessively cold damp weather in April and especially in May, is the main cause of rust in this cereal.

MAIZE.

This catch crop is exceedingly valuable to the cow-keeper. With a dry spell of weather in August and September the pastures quickly become short of grass, and then green Maize gives a fillip to the milk supply. Again in October, even if not required in the two preceding months, Maize is valuable, as by that time the grass will probably be lacking in quality. Maize given daily not only improves the quantity of milk, but its quality also. No time should be lost in sowing the Giant Horse Tooth or the Virginian variety, at the rate of one bushel per acre. Sow the seed thinly in every plough furrow, scattering along with the seed superphosphate at the rate of 3 cwt. per acre, where no farmyard or other manure was used.

CARROTS.

Complaints are common among gardeners that Carrots are not a full or even crop. My acre of Scarlet Intermediate has a capital plant. Thin the plants to 9 inches apart; too many plots of this crop are spoilt through neglect in thinning early. Keep the soil between the rows well stirred to keep down weeds and hasten the growth.

SUNFLOWERS.

The plants raised under glass and put out a month ago are now 15 inches high. They look strong, and likely to reach 7 feet high. Some method of supporting their stems must be devised to protect them from a strong gale. String, wire, or small stakes stretched horizontally along the rows at intervals would afford the necessary protection.

The sown plants, one foot a few inches high, sturdy, and promising. The recent dry weather is in favour of them getting out of the way of slug attacks, especially if the soil between the rows is frequently stirred.

RAGWORT IN PASTURES.

This obnoxious weed is growing luxuriantly in some pastures where its removal last autumn was neglected. Being a perennial it is useless to cut off the stems. Nothing short of digging up the whole plant is efficient. Ragwort is, in my opinion, one of the worst weeds possible in a pasture where milk cows graze. *E. Molyneux.*

THE HARVEST OUTLOOK.

The reports as to the cropping outlook received by the Food Production Department up to last Week-end from the Departmental Commissioners are uniformly encouraging. Never have the Wheat and other corn crops in England and Wales as a whole looked better than they do at the present time; grass is generally good, and roots are promising.

"The promise of nearly all crops is high," says the Berks, Bucks, Oxon, and Wilts Commissioner, "and it looks as if the harvest of 1918 will be far above the average. The Wheat in particular is in the better land districts of quite exceptional promise." In the Pewsey Vale it is reported that "piece after piece has enough plant on it to produce 10 quarters to the acre if the corn stands up till the day of harvest." A farmer of long experience farming 7,000 acres of land states that he has never grown such Wheat as he has to-day, and that "200 acres out of his total Wheat area of 1,600 are better than he has ever seen on any land before."

The weather may damage these crops before they are harvested; however, much of the land in this area is sown with the variety of Wheat known as Benefactor, which, as experience proves, will stand a great deal of knocking about. "During the last season this variety could be seen still upright when others were hopelessly laid."

Many of the reports from the Home Counties describe the Wheat as "too good."

There has been much talk about damage done by wireworm and leather-jacket to spring corn on newly ploughed grassland. The Commissioner for Berks, Bucks, Oxon, and Wilts declares that he has satisfied himself "that this damage is less than has been generally reported, and that many pieces have recovered from the attack." A general survey of the country by representatives of the Department confirms this view. Where serious damage has been done by pests on newly ploughed grass it appears to have been usually associated with defective consolidation of the soil. In a large proportion of cases examination has shown that the damage was done by slugs, and not by wireworm at all, as had been reported. Most of the land where corn crops had failed has been sown or planted with other crops, which now apparently are doing well. There is certainly no cause for pessimism with regard to "ravages of wireworm and leather-jacket." A certain amount of damage was anticipated by the experts of the Department; and, so far, the actual harm reported has been no greater than was expected.

The Commissioner for Somerset, Devon, and Cornwall says: "The country is looking exceedingly well, and from very experienced agriculturists I am informed that the damage by wireworm is not so great as normally. The crops promise to be excellent. Potatos were lifted in the parish of St. Paull, near Penzance, on May 21."

The Wheat crops in the Fens are exceptionally good, says the Lincs, Rutland, and Notts report. The Pea crops appear to be satisfactory everywhere. There will be little difficulty this year in securing plants of Mangolds, which last year gave much trouble. Grass is abundant, and live stock are improving in condition.

From Salop and Staffs it is reported that corn and grass have "never been seen to grow with such extraordinary rapidity as this season."

The Commissioner for Hants, Dorset, and the Isle of Wight states that corn crops generally continue to look well.

In Lancashire and Cheshire the hay harvest promises to be up to the average in bulk, whilst many corn crops, which formerly looked sickly are now showing considerable vigour.

From Worcestershire it is reported that the Victoria Plums were cut by the frost. Egg Plums are affected by blight and will be only a partial crop, and caterpillars are damaging the Apples. But it is satisfactory to know that the fears entertained in mid Wales and some other districts that unfavourable weather early in the season would have damaged the fruit crop seriously do not seem to have been realised.

MARKETS.

COVENT GARDEN, June 12.

Plants in Pots, &c.: Average Wholesale Prices.

			Moss, gross bun...	7 0-	8 0
			Smilax, per bun. of 6 trails ...	4 0-	4 6

REMARKS.—Supplies of cut flowers are more regular, and prices in many cases are easier. Pyrethrums are getting towards the finish. White Pinks (Mrs. Sinkins) and White Stock are sufficient for the demand. White and coloured Paeonies are offered in excellent condition. There is also a good selection in Sweet Peas obtainable from 6s. to 24s. per dozen bunches. Spanish Iris is arriving in much better condition, chiefly from home growers. A few boxes of these blooms are being sent from Guernsey, and when cut in bud they open out well. There is little improvement in the quality of Roses; a few outdoor blooms are being offered. Mrs. J. Laing being most in demand. Other flowers on offer are Cornflowers, Coreopsis, Nigella, Poppies, Gypsophila, Canterbury Bells, and Delphiniums.

Lettuce, Cabbage and Cos per doz	0 6-	1 6			
Mint, per doz. bun.	4 0-	6 0			

REMARKS.—Strawberries are now the ruling article in the fruit trade. The market is still well catered for from Southampton with the usual 2lbs. and 4lbs. packages; they are also now beginning to arrive from Kent in pook baskets. Cherries (the first early varieties) are now arriving in half sieves (24lbs.). Grapes (Black Hamburgh and Muscat of Alexandria), Melons, Peaches, Nectarines, and Figs are all plentiful. Tomatos have not been so plentiful as usual at this time of year. Cauliflowers are scarce and expensive. Mushrooms are fairly plentiful. Peas (outdoor) are now well in evidence. A further consignment of Egyptian Onions reached the market this week; the bulbs realised lower prices. Cucumbers continue expensive for the time of year. Some fine samples of Englishgrown Asparagus are still on offer.—*F. H. R., Covent Garden Market, June 12, 1918.*

ANSWERS TO CORRESPONDENTS.

ASPARAGUS: *A. J. G.* We found the mycelium of a fungus present on the specimen you sent, but it was barren, and could not be identified. We presume that the specimen was taken from one of the beds which you say are not succeeding, and we would advise you to pull up and burn all the diseased plants, and spray the rest with Bordeaux mixture after the crop has been cut. Fungous disease is not common in Asparagus, and is usually the result of unfavourable conditions, such as drought, or want of nourishment in the soil.

CARNATIONS: *J. A. B.* The dark spots on the leaves of the Carnations do not resemble the effects of any fungous or insect pest. Perhaps you have sprayed the plants with some insecticide or fungicide at too great a strength.

"FLAT" OR CUCUMBERS: *W. E. B.* The number of Cucumbers continued in a market "flat" varies from 4 dozen to 2 dozen, according to the size of the fruits.

GRAPE FRUIT: *D. B.* The Grape fruit is usually budded on its own seedlings, the bud being taken from a named variety. You must not, however, expect to be able to grow this fruit successfully in the open in this country. The plant is exceedingly susceptible to cold, and will not survive anywhere above what is termed the frost-line. The botanical name is Citrus grandis. The plant is listed as Citrus paradisei in Messrs. T. S. Rivers and Son's catalogue, from whom you should be able to obtain grafts.

HEDGE DYING: *C. N.* As you do not send us a specimen of the Privet, we cannot say if there is any disease which might cause it to die; but the trouble you describe might be due to natural causes. Privet is very susceptible to drought, and this condition is often present in small front gardens, where the soil put in by the builder is frequently quite unsuitable to plant life, and what little moisture is present is absorbed by the brick foundation of the railings. We should advise the tenant to grub up all the bushes which appear to be past cure, and buy new plants (which are very cheap), enriching the soil as much as possible with well-rotted manure and leaf-soil before putting them in.

NAMES OF PLANTS: *Dolomite.* Crepis hieracioides, one of the species of Hawk's-beard. It usually grows in mountain woods.—*Bradford.* Geranium pratense. It is often cultivated as a garden plant.—*T. G. S.* 1, Solanum species; 2, Thunbergia alata.—*Miss P., Cork.* Crambe maritima.

ONIONS FOR KEEPING: *J. L. W.* Onions should be stored for winter use in a dry, frost-proof shed or other structure. Cold is not so injurious to them as damp, which will quickly spoil them, and favour attacks of mildew. As regards varieties, some keep much longer than others, and when sowing seed this point should be borne in mind. For instance, Ailsa Craig and Giant Rocca, which are excellent varieties for immediate use, will not keep; for this purpose you should choose some variety such as James' Long Keeping or Autumn Triumph. Specimens of the latter variety have been known to keep well for two years. Spanish Onions keep well, not because they are "treated" with anything, but because, by reason of climatic and other conditions, they develop the hard, brown skin which enables the bulbs to be safely stored without fear of their sprouting. The warm, dry climate of most parts of Spain is ideal for the development of this quality.

PEAR SHOOTS DISEASED: *Argyllshire.* There is no fungous or other disease on the portion of the shoot sent; perhaps the trouble arises lower down the shoot.

PLUM TREES DYING; *T. E. W.* Your gardener is not alone in knowing very little about the cause and cure of Silver Leaf disease, as it is a most obscure complaint, and the discovery of a remedy has hitherto defied all efforts at research. The only thing to do is to examine the Greengage tree carefully, and cut away and immediately burn all diseased branches and twigs well behind the discoloration. Do the same with all other Plum or Apple trees growing in the vicinity. If this is not successful, grub up the whole tree and burn it, and also dig up the soil in which it was growing and replace it by fresh compost, before planting other specimens.

ROSES; *M. H. G.* What you call "cankers" are not those of Coniothyrium; in fact, there is no fungus disease on the plants. Canker is sometimes purely physiological, e.g., the result of frost, or of the use of unsuitable stock for grafting. You state that some of the trees are affected by "spot"; if there are blackish blotches with reddish-purple borders on the upper surface of the leaves, it may be Septoria rosarum; but there is another similar spot, which is practically harmless. In any case, spray the trees with a dilute solution of copper sulphate, keep them well pruned, and expose them fully to the sunlight and air.

SOIL: *L. C.* If the drain pipes in your land are 18 inches deep, that is quite suitable; but they are evidently not sufficiently near to each other. We should advise you to supplement them by straight trenches, one between each pair of pipes, a foot to 18 inches deep and a foot wide, filled with coarse clinkers. These will do much to assist the drainage of the land, though not quite so efficiently as pipes, which are not so easily choked with silt and soil. Needless to say, the drainage should run from the highest to the lowest level of the ground. When you are digging the soil, make a point of incorporating with it anything which will tend to lighten and separate it, such as sand, gravel, old mortar rubble, decayed leaves and leaf-soil, and well-rotted manure.

TULIPS DISEASED: *M. H. G.* The Tulips are attacked by a fungus disease, Botrytis parasitica. Pull up and burn any infected plants, and, if possible, sterilise by burning all the soil in which they were growing. We should advise you also to remove the healthy bulbs to another part of the garden; the disease will not attack Roses. Be careful, however, not to retain any plants which show the least symptoms of disease, such as have brown velvety patches on the stem or leaves.

LONDON TREES.

LONDON might well be called "The City of Plane Trees," for unfortunate though it may be from the point of view of sameness, it has been computed that fully 60 per cent. of the arboreal vegetation in the metropolis consists of this tree. The Elm, Lime, Poplar, Acacia and Ailanthus are all more or less common, but the so-called London Plane has ousted nearly every other tree from the field; indeed, during the past five-and-twenty years it has been planted to the exclusion of almost every other species. That it succeeds as well, if not better, in the London area than the majority of trees must be admitted, but the almost monotonous repetition in our streets, squares and public gardens of this particular Plane is to be deplored, and has been the cause of much unfavourable comment during recent years. So far as I am aware there is not a public or private garden, square, park or open space in London where the Plane has not been planted, often to excess, while the majority of streets, wide or narrow, sheltered or exposed, have been planted with the same tree. The Ailanthus succeeds quite as well as, and perhaps better than, the Plane in the most confined and smoky districts, while the Acacia, common and weeping Ash, Laburnum, Mulberry, Catalpa, and many beautiful species and varieties of Pyrus and Thorns, are all not only highly ornamental, but well suited for planting both in urban and suburban districts. For small areas, such as most of the London squares, the Plane, being of large growth and one of our noblest forest trees, seems rather out of place, and, owing to its tall, usually branchless stem, imparts a bare, unfurnished appearance to these gardens, especially when used alone or with few other smaller-growing trees and shrubs as underwood. In comparing Berkeley and Hanover Squares, where little else but Planes has been planted, with, say, Bedford, Russell, or Gordon Squares, with their neatly kept turf and well-grown specimens of the weeping Ash, Thorns of various kinds, the beautiful cut-leaved Pyrus, Ailanthus, Laburnum and Holly, which impart a cheery, furnished aspect, the difference is very pronounced, and especially during the winter. In St. James's Square only a few trees of Ailanthus, Thorns, and two solitary Elms relieve the monotony produced by the Planes, which in this instance are rather poor and weedy. Leicester Square follows suit with excessive Plane tree planting, while the nineteen trees in Trafalgar Square are other examples of the too free use of a single species. In Hanover Square two half-dead Thorns and a small Chestnut struggle for existence with giant Plane trees.

Most of the new streets and roads have of late years been planted with the Plane, and a nurseryman in the suburbs informs me that fully 75 per cent. of his London orders have been for this tree. To the casual observer the variety of trees to be found in London may appear small, but such is by no means the case; indeed, the number of distinct species is a comparatively large one. It is only after a careful examination of the trees in our streets, squares and open spaces by an interested person that the number of different kinds can be realised, for unless the examination is made by one acquainted with the peculiarities in form and foliage of various trees, many of the less common kinds are apt to be overlooked. Few Londoners, perhaps, know that in the central parks alone upwards of two hundred and twenty distinct trees are cultivated, that a number of healthy Catalpas are growing by the Clock Tower at Westminster, the Judas tree, Liquidambar and Black Walnut at Fulham, Paulownia and golden Catalpa in Regent's Park, or the Mulberry in Finsbury Square. In the smoke and dust of Chelsea many of the less common trees flourish amazingly, including the Paper Birch, Catalpa Kaempferi, Ginkgo biloba (Maidenhair tree), Prunus Padus (Bird Cherry), and Koelreuteria, while the magnificent Hickories and Arbutus (Strawberry tree) in Waterlow Park, Liriodendron tulipifera (Tulip tree) at Golders Green, and the Maidenhair tree by the Commercial Road and other parts of the East End are surely sufficient evidence of how well other trees as well as the Plane succeed in different parts of London. Of the commoner trees, such as the Ash, Elm and Acacia, there are magnificent specimens both in Hyde Park and Kensington Gardens, while the gigantic Poplars and Willows by the lake side in St. James's Park have few equals even in the open country. The Ailanthus grows freely in all the parks, as does the Manna or Flowering Ash, while the various forms of Acer or Maple, Prunus and Pyrus, all show by the age and size to which they have attained how well suited they are for thriving in the impurities of a town atmosphere.

The Ailanthus grows in London quite as well as the Plane; indeed, in certain confined East End districts, as by the church of St. Magnus the Martyr, near Billingsgate, it has ousted the Plane, though both are growing in exactly similar conditions and within a few yards of each other. The power in certain trees to withstand the chemical and other impurities of a town atmosphere is owing largely to a hardy and robust constitution, but the quality of the soil in which they are growing has its effect; and it is a curious fact that the Plane is not the best tree for planting in Sheffield or Manchester, where soil and other conditions are different from those in London. It is generally supposed that the annual shedding of the bark is the reason of the Plane tree succeeding so well in London. This is, however, scarcely borne out by facts, as several other trees which do not shed their bark thrive equally well, amongst them the Ailanthus, Poplars of several kinds, the Acacia, Mulberry, many varieties of Pyrus, Prunus and Crataegus.

The bark of the Acacia remains intact for many years, and, being so rough and furrowed as to make the trunk deeply fluted, collects dust and other atmospheric impurities in large quantities, so much so that seedlings of other trees frequently spring from amongst the debris in nooks and crannies of the stem.

That the Plane is, whether in point of ornamental value and shade, or from its ability to thrive well in smoky localities, a valuable tree for planting in London, cannot be denied; but the limit of numbers has long ago been reached, and unless a speedy check is put on its indiscriminate use the future of the metropolis from a purely arboreal point of view will be monotonous in the extreme. *A. D. Webster.*

THE MARKET FRUIT GARDEN.

FUNGOUS DISEASES.

I HAVE always considered a dry May to be unfavourable to the spread of fungous diseases. There is, however, a serious attack of brown rot on Czar and President Plums, not only in my plantations, but on other trees in the district. Many spurs and branches are quite brown and dry, giving the trees a half-dead appearance. They should not be given up as hopeless, however, as similar trouble with Pond's Seedling in a previous year has been overcome. The brown leaves and spurs and dead shoots should be cut out at once and burned, to prevent the spread of the disease. Similar treatment is necessary with varieties of Apples that are attacked by canker on the young wood. I have a very bad example of this in some young trees of James Grieve. Up to the present the trees have made splendid growth, but now they are beginning to canker badly. In some cases it has been necessary to cut out about a third of the tree. Apparently this variety is going to repeat the behaviour of Cox's Orange Pippin here, trees of the latter starting well, then cankering seriously for several years, but eventually recovering after persistent treatment with the knife. Whether the labour is worth while in the case of James Grieve is doubtful. This variety does not yet find much favour in southern markets, though it appears to be very popular in the north.

Apple bloom wilt, a somewhat new disease which has done much damage in the past few years, has made its annual appearance on Domino and Early Julyan. It is, however, less plentiful than usual, because there are fewer trusses for it to attack. Lord Derby, the worst variety for this disease, has no fruit, so that it is not troubled by blossom wilt this year. Affected trusses should be cut out promptly to

prevent the spread of the canker which follows the wilting of the blossom.

LUCERNE AS A COVER CROP

A plantation of Apple trees sown with Lucerne last year was mown for the first time for the season at the end of May. There was a fairly good crop, though largely intermixed with Red Clover and grasses. The growth is to be left on the ground as green manure, the object being to test a plan of manuring the trees which is common in the United States, a further advantage being the saving of labour in digging and hoeing cultivated plantations. So far the trees look none the worse for the presence of the cover crop. One thing is noticeable, though it may be due to mere chance: winter moth and allied caterpillars have been less serious in this plantation than in those that are cultivated. It is possible that the more solid ground makes it difficult for the fully-fed larvae to penetrate for pupating purposes, or for the moth to emerge from the pupae. *Market Grower*

TREES AND SHRUBS.

ESCALLONIA LANGLEYENSIS.

THIS hybrid Escallonia is remarkably handsome when laden with its clusters of rose-carmine flowers. It is as a rule at its best in the month of June. The flowers are soon over, but this applies equally to many other flowering shrubs. Escallonia langleyensis was raised at Messrs. James Veitch and Sons' nursery at Langley, by John Seden, who, after a very successful career as a raiser of hybrid Orchids and other indoor plants, went to Langley and devoted his attention to hardy plants of all kinds, both flowers and fruits. In *Hortus Veitchii* the parentage of E. langleyensis is given as E. Philippiana fertilised with the pollen of a dark variety of E. macrantha known as sanguinea, but Mr. Bean, in *Trees and Shrubs Hardy in the British Isles*, states that the parents are Philippiana and punctata. The hybrid was given an Award of Merit by the Royal Horticultural Society in 1897, but it must be regarded as well worth the higher honour of a First-class Certificate. Being of somewhat lax growth, this Escallonia is eminently fitted for clothing an unsightly fence or similar positions. If the main branches are fastened in their place, and the secondary ones allowed to grow at will, the tree forms, from the arching, semi-pendulous character of the shoots, an exceedingly graceful specimen. In the nursery at Coombe Wood there was a large plant of this Escallonia (I believe the original one), trained as a flat screen, the branches being supported by stout stakes. It was in this way very effective. By some this Escallonia is referred to as an evergreen, but in my suburban garden in the south-west of London, on a cold, clayey soil, it loses nearly all of its leaves in the winter. It is advantageously employed in hiding the ugly tarred fence so conspicuous in suburban districts. Cuttings are particularly easy to root if taken towards the end of the summer, inserted in a close frame, and shaded from direct sunshine. *W. T.*

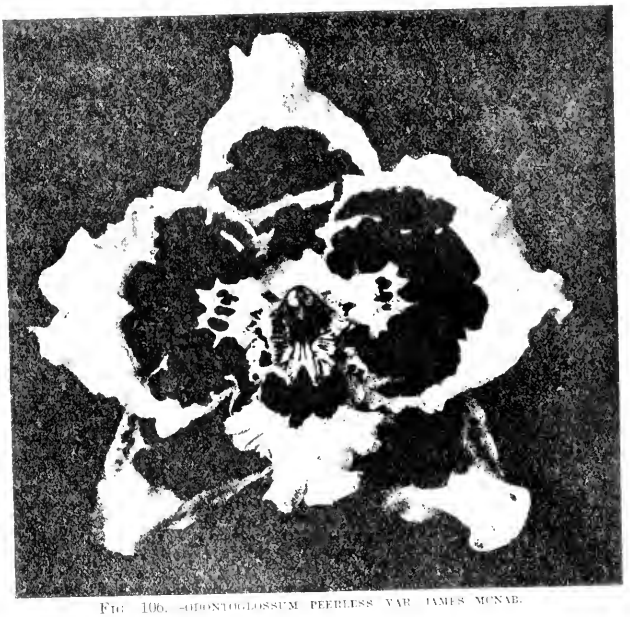

FIG. 106.—ODONTOGLOSSUM PEERLESS VAR. JAMES MCNAB.

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM PEERLESS VAR. JAMES McNAB.

THE beautiful forms of Odontoglossum Peerless raised by Messrs. Armstrong and Brown, by crossing O. Ossulstonii (crispo Harryanum × Pescatorei) and O. eximium (ardentissimum × crispum), two of which have, as seedling plants, secured the Preliminary Commendation Award of the Royal Horticultural Society, give excellent examples of good results obtained by crossing with a definite purpose. The lineage in the variety James McNab (see fig. 106) includes O. crispum thrice, O. Pescatorei twice, and O. Harryanum once, blotched forms of O. crispum being used to secure good colour and large size, and O. Harryanum to impart firm substance. O. Pescatorei gives the fine form, and especially the broad development of the lip, which is clearly indicated in the variety James McNab.

The flower is 4 inches across and the petals are 2 inches in width. The ground is white, the inner parts bearing large, confluent, ruby-red blotches; the petals have a small white base with red spotting, and both sepals and petals have a broad white margin. The lip is white, with a ruby red blotch in front of the crest.

A MESOPOTAMIAN CALENDAR.

January.—Most trees in Mesopotamia are evergreen, but the Willow, Fig, Mulberry, Vine, and a species of Mimosa—the only winter-flowering shrub, are now leafless. The Euphrates Poplar, though its leaves are bright yellow, forming brilliant spots of colour in the sunshine, has not yet shed them. In the Palm groves Wheat and Lucerne are coming up, and the desert is being ploughed in the neighbourhood of each village. Irrigation ditches are also being dug from the river. There is a semi-aquatic Ranunculus in flower, and Capsella Bursa-pastoris, but I have seen nothing else. The nights are still cold, with frosts sometimes in the early mornings; the days bright and sunny, warm when there is no wind. A few days' rain may be expected.

February.—Spring begins. In the shelter of the Palm groves, along the irrigation creeks, familiar flowers, such as Ranunculus aquatilis, Polygonum sp., and one or two grasses, come into bloom. There are no more night frosts, and though there are rainy days, and in some districts, at least, clammy mists in early morning, the weather is on the whole genial. Towards the end of the month the racemes of the Date Palm begin to appear beyond the tip of the spathe.

March.—The month of flowers. The Mulberry and Willow are in flower early, also the Euphrates Poplar. Along the creek side are English wild flowers, such as Geranium sp. (crimson), Vicia sp. (purple), Euphorbia, Clover, Anagallis (two species, one with scarlet flowers, possibly A. arvensis, the other with bright gentian-blue flowers), Hieracium, and Veronica; also several aquatic plants. By the middle of the month the gravel desert above flood level is covered with flowers, mostly dwarf, including many "rosette" plants. They include a white-flowered Salvia, dwarf Iris, Euphorbia, Geranium (two species), Vicia, (two species), Asphodel (two species), Compositae, an Umbellifer, Potentilla sp., and many more. There are heavy dews in the early morning, which are perhaps the source from which these plants obtain their water. The silt desert, which is saline, owing to periodic flooding, supports only Samphire and patches of "Camel Thorn"—a Leguminous undershrub with the appearance of Gorse.

By the end of the month the Lime and Orange trees are in flower, and the Fig trees and Vines in full foliage. The Liquorice is coming into leaf, and the Wheat is almost ripe.

April.—The days begin to get very hot, but the nights are pleasantly cool; it is the end of spring. There are dews in the early morning, but rain is quite exceptional. The Pomegranates and Oleanders are in flower, and a beautiful Caesalpinia tree. All trees are in full leaf. There are still many flowers in bloom by the creeks, but they are already past their prime, and some are seeding, while on the desert many of the plants in flower last month are already shrivelled. The Tamarisks come into bloom, and also Liquorice. In the creeks Frog-bit, Mares'-tails, and other familiar English aquatics are in flower. The Arabs are busy pollinating the female flowers of the Date Palm, carrying about the huge, jaundiced, male racemes.

May.—The Mulberries ripen, and the pretty crimson-flowered "Camel Thorn" comes into flower (it is a small Gorse-like under-shrub belonging to the Leguminoseae, which grows on the desert, on old walls, and in the Palm groves). At the beginning of the month a magnificent shade-giving Leguminous tree is in flower, but it lasts scarcely a fortnight, and by the end of the month all the flowers are gone. In June it flowers again for a short time, and I saw it in bloom once more in September. The leaflets of the large, compound leaves close together, and hang limply from the depressed leaf-stalk. By day, even in the hottest weather, they are wide-

spread, their polished surfaces reflecting the light. There is another fine tree which flowers this month, and behaves in a similar way, the last spasm of flowering being October. It belongs to the Celastraceae. Thus there are two flowering seasons, spring and autumn, separated by hot and cold seasons. By the end of May the

FIG. 107.—KORAH CREEK, NEAR BASRAH, MESOPOTAMIA, FORMERLY FULL OF DATE PALMS AND VINES AND SOME BANANAS.

shade temperature had reached a maximum of 110° F.

June.—There are heavy dews soon after sunset. Dust storms are frequent, the earth's cold tempering the great heat. The Wheat and Rice crops are reaped at the beginning of the month. Oleanders cease flowering in the autumn, but there are still a few flowers by the creek. Verbena officinalis, Plantago sp., Compositae, Convolvulus sp., an Umbelliferae, and others. Lotus and Satsuma are seen floating in the ditches. In many of the Palm groves is a thick undergrowth of Liquorice, "Camel Thorn," a white-flowered Myrtle smelling of cloves, and a Leguminous undershrub, with purple flowers, moss overt, and highly varnished leaves.

July.—The terrific heat, reaching 130° F. in the shade, shrivels up all the desert plants. By the river two species of Erygonum and a sweet-scented Clover are still in flower; also the Myrtle just referred to. On old walls a Leguminous undershrub with fleshy leaves is in flower and fruit simultaneously, and remains in flower all through the hot weather. There are daily dust storms, and notwithstanding the heat of the day the nights are comparatively cool. No trees are in flower, but all retain their leaves throughout the hot weather, in spite of there being no rain, thus differing from most of those in the monsoon region. The Grapes are ripe, also Water Melons. Winter crops of vegetables are planted on the majority on banks exposed by the falling river, and irrigated.

August.—The intense heat shows signs of decreasing. Towards the end of the month heavy white mists lie over the river and desert in the early morning. The Pomegranates ripen at the beginning of the month, the Dates at the end, by which time the Arabs are busy picking and sorting them. An occasional prostrate Convolvulus is seen in flower out on the dry silt desert, and in pits protected from the scorching wind are a few "rosette" plants with deep tap-roots. Polygonum sp., Potentilla (two species), Malva sp. (not in flower), and a few others. The Myrtle is still in flower, with ripe fruits.

September.—The sixth month without rain. By the middle of the month the early mornings are very pleasant, as are the evenings. It is still very hot in the middle of the day, and the north wind has ceased, but the drawing in of the days makes a big difference to the nights. It is the autumn flowering season, and in the [illegible] flowers in bloom, including Verbena officinalis sp. Orobanche sp. several Compositae, Convolvulus, two species Oxalis sp. Mint, and two or three grasses. In marshy and meadow ground exposed by the subsiding water are patches of Cuscuta on Liquorice and other plants, trailing Convolvulus, and a beautiful little trailing Toad-flax; in some places a species of Cerastium, growing socially, so as to form a thick carpet 6 inches thick, was seen; in other places, a yellow-flowered plant belonging to the Saxifragaceae grew in the grass; also patches of Butomus umbellatus. In the gardens the crops of "Ladies' Fingers," Cotton, etc., are 4 to 6 feet high. Beans, Tomatos, Cucumbers, Marrows and other vegetables are ripe.

October.—Very similar to last month, but cooler. Plenty of flowers, both wild in the desert and in gardens. Roses, Sunflowers, Hollyhock, Jasmine. The Oleanders are in flower again, and so for a short time is the big tree—N.O. Celastraceae—referred to previously. The long grass and flowers of the desert meadows are cut by Arabs, and the ground, formerly green, again takes on the aspect of bare desert. Towards the end of the month it becomes too cold to dine outside at night.

November.—The end of the autumn flowering period; many of the plants enumerated above are still in flower. By the middle of the month the Mulberry trees are shedding their leaves, as also are the Willows, while the Poplar leaves are turning. The Sweet Limes are ripe, though still green. The last of the Cotton and vegetables are gathered, including Indian Corn, and everything rooted out of the gardens for fuel, so that they look as bare as the desert again; a month later they are ploughed and Wheat sown.

December.—After an eight months' drought, rain may be expected any time. The weather turns very cold, with bitter north winds and frost at night, except when rain falls. Oranges and Sweet Limes finally ripen in the winter sunshine, and deciduous leafed trees become bare. There are dense mists, sometimes lasting through the night. The Palm groves, washed of their dust by the rain, look fresh and beautiful for the next two months. As soon as the rain comes seedlings may be seen springing up everywhere in the desert by thousands. The yellow-flowered Mimosa is in bloom, but very little else; a few ephemeral flowers, however, such as Shepherd's Purse, may be found, as in England in winter. *F. Kingdon Ward.*

SOME GARDEN PESTS.

INSECT pests are extremely abundant this year. In this part of Yorkshire the leather-jacket, the larva of the crane fly, or Daddy Longlegs, has been and still is a scourge. It

FIG. 108.—POPLARS, WILLOWS, PALMS AND MULBERRY TREES IN MESOPOTAMIA.

has attacked Cabbages, Peas and Beans. The plants may be severed by the insects from their roots, upon, or immediately beneath, the surface of the soil. I was recently called upon to inspect a row of Peas that had been completely ruined by leather-jackets. The adult insect lays her eggs in the autumn, and the larvae appear

about a fortnight later. They commence to feed in the first warm days of the year. There are various preventive and remedial measures. Undrained grass-land or badly kept water-courses in the proximity of gardens are favourite egg laying stations. Wherever possible drainage of the former and cleansing of the latter should be done. Observers of crane flies will have seen them hovering upon patches of grass that often grow in waste corners of gardens. The grubs will give trouble later, which may be obviated by removal of the grass. An application of nitrate of soda or sulphate of ammonia will often so stimulate an affected crop that it can more than repair the damage. Soil fumigants and various proprietary articles are sometimes recommended, but from my experience they are without the slightest effect. I have many times given them a fair trial. As many adult insects and larvae as possible should be killed.

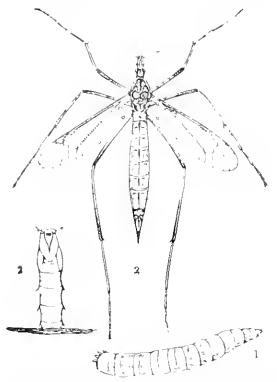

FIG. 109.—THE CRANEFLY, OR "DADDY LONGLEGS" (TIPULA OLERACEA). 1, THE GRUB; 2, THE PUPA; 3, THE PERFECT INSECT.

The eggs of the Onion fly are laid upon the neck of the bulb in late April and May. The grubs hatch quickly, eat the tissues of the bulb, and pupate. In about three weeks flies appear and the process is repeated. A third generation sometimes appears in the South of England, but I have not observed such in the North. Pupae that are produced in autumn pass the winter in the ground, therefore Onions should not be grown on infected land for some years. It is well to dress the Onion crop with soot about the time the flies appear. The pungent odour may drive them away, and at the same time the soot assists the plants. Onions raised under glass are seldom affected. They are stronger and thus better able to withstand attack.

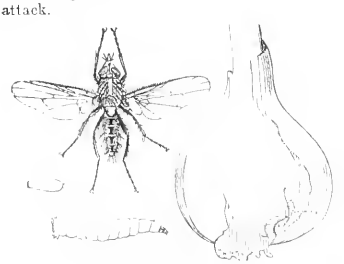

FIG. 110.—THE ONION FLY—ANTHOMYIA CEPARUM (MAGGOT AND PUPA, MAGNIFIED).

Aphides and red spider infest many crops. They pierce the tissues and extract the cell-sap. Multiplication in their case is extremely rapid, therefore prompt measures should be taken to meet an attack in its initial stage: 1 lb. of soft soap and 1 lb. of Quassia extract mixed with 20 gallons of water is an excellent specific.

The time is at hand when we may expect an outbreak of the Potato disease (Phytophthora infestans). Wise cultivators will protect their crops by spraying with Bordeaux mixture or Burgundy mixture. Bordeaux mixture is made by mixing 1 lb. of copper sulphate, 1 lb. of fresh lime, with 10 gallons of water. The first spraying should take place about the third week in June and be thrice repeated at fortnightly intervals. In making Bordeaux mixture no metal vessels should be used. The copper sulphate and lime should each be dissolved in half-a-gallon of water. Mix them together and add the 9 gallons of water slowly. *Geo. H. Copley, Horton Park Gardens, Bradford, Yorkshire.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey

POTATOS.—On the whole, the Potato crops look very promising; the plants came up well, grew strongly, were uninjured by frosts, and are fully a fortnight earlier than usual. Potatos rarely show signs of late blight disease until about the first week in July. The best preventive to blight disease is spraying with a preparation containing copper sulphate, and spraying not only prevents disease but increases the weight and quality of the crop. Bordeaux mixture is largely used, and may be obtained from local chemists, with full directions for use. The foliage should be sprayed on the under as well as the upper surface. Many do not consider it necessary to spray early varieties, which are lifted before the disease is likely to do much harm. Late varieties should be sprayed twice, on the first occasion at the end of June, and the second time in the middle of July.

ASPARAGUS.—Early Peas will be ready for gathering after this date, and there will be no need to cut much Asparagus when Peas are plentiful. It is harmful to cut the shoots from new Asparagus beds until at least two seasons have passed, nor should the shoots in comparatively young beds be cut late in the season. Old beds may be allowed to furnish late supplies if early Peas are scarce, but the shoots should be only carefully thinned and the remainder allowed to develop. If the growth is thinned judiciously fewer but finer buds will form, and give superior produce the next season. Seeing that the loss of the best shoots after this date must greatly weaken the plants, it behoves the cultivator to preserve them as much as possible. The same remarks apply to young beds. Strong, feathered Pea sticks should be put to the plants to prevent damage by strong winds, and the beds kept clear of weeds by hand-weeding.

FRAME CUCUMBERS.—Cucumber plants in frames in full bearing will require attention at least three times a week. Pinch each lateral at the first or second joint beyond the fruit and keep the bed evenly covered with foliage. The roots should be given soft water at a temperature of 80°, and this may be varied by the use of soot-water once or twice a week. When root-feeding is necessary the surface of the bed should be flooded without wetting the foliage, in bright, sunny weather. Fresh linings of dung should be applied from time to time throughout the season, first at the front of the frame and then at the back.

CARROTS.—Those who require a constant supply of young, tender Carrots should make another sowing at once. Select one of the stump-rooted varieties, and sow the seed in rather light soil in drills made 9 inches apart. If the plants are lightly thinned and kept clear of weeds a good supply of roots should be forthcoming early in the autumn. If very small roots are desired sowings should be made in July and early in August in a frame.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to Mrs DEMPSTER, Keele Hall, Newcastle, Staffordshire.

THE ORCHARD HOUSE.—The fruit in these houses will now have reached the final thinning stage. Be careful to limit the crop according to the age and condition of each tree. Pot trees are usually so restricted for root space that the welfare of the trees is entirely dependent on stimulants. If there is not sufficient space for top dressings, place pieces of zinc or tin around the inside of the pots, and then fill up with rich compost, preferably a mixture of decayed manure and loam. Diluted liquid manure should be given frequently, and the syringe freely used to keep the foliage clean. Established trees in borders carrying heavy crops require similar treatment, except young trees which are already making too vigorous growth. Trees that fruit on spurs, such as Apricots, Plums, and Cherries, should have the young shoots pinched back to a few leaves, but those at the end of the branches should be left to grow for the present. However carefully Peach and Nectarine trees have been disbudded there are always a few superfluous shoots. Cut these out, retaining those most favourably situated for next year's fruiting.

POT VINES.—Suitable top-dressings and liberal supplies of diluted liquid manure will greatly improve pot vines intended for next year's forcing. The roots must not be allowed to get into the plunging material. If the plants have been stopped at the proper height the canes quickly thicken. As the young rods change colour more fresh air and warmth will be beneficial. Keep the laterals closely pinched from the base to the pruning-point, but on no account should those above be defoliated; they must be left for the present for the plants to draw nourishment from, so as to complete their growth. Syringe these young vines freely to keep the foliage clean and free from red spider.

MELONS IN FRAMES.—Pits and frames that have been cleared of bedding plants may now be planted with Melons. The sun will provide most of the heat necessary. Make up a bed of sweet manure and leaves in equal proportions, and on this arrange a ridge of retentive loam, with which a little mortar rubble and wood ash has been incorporated. Ram the soil firmly, and directly the bed is warmed through the plants may be inserted. Admit a little air in the mornings on bright days, gradually increasing the amount as the sun gains power. Syringe the plants freely at about four o'clock in the afternoon, and then close the frames.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

ZYGOCOLAX AND BOLLEA.—Zygocolax Pescatorei and Colax jugosus may be grown in the same house as Zygopetalums, and should be shaded from strong sunlight. Plants of the allied genera Bollea and Warscewiczella should receive attention in re-potting or top-dressing just after they commence to make new growth. These plants should not be subjected to root disturbance unless it is quite necessary. They may be grown either in pots or pans, which should be provided with ample materials for drainage. As a rooting medium employ a mixture of three parts A 1 fibre and one part clean, picked Sphagnum-moss. Cut both materials into rather short portions, adding a good sprinkling of crushed crocks and a few small lumps of charcoal. The plants grow best in a moist, shady position in the intermediate house. Re-potted plants should be watered sparingly, but the spaces between the pots and their surroundings should be kept in a moist condition always. When established the plants should never be allowed to become quite dry at the roots.

VANDA.—As plants of Vanda trees pass out of flower they should receive attention at the roots. Specimens that have become "leggy" and have lost a quantity of the bottom leaves should be cut down to a desired length below some of the aërial roots, and potted again as compact specimens. The portions may be potted singly, or three or more stems may be placed together

in pots of a suitable size, or in narrow boxes or troughs. Whichever receptacle is employed, it should be provided with clean crocks for drainage purposes. A suitable compost is equal parts Osmunda-fibre or A 1 fibre and Sphagnum-moss, cut up rather short, mixed with crushed crocks and small lumps of charcoal. Plants that do not require to be cut down should have all the old soil washed from their roots, and new soil provided. This Vanda is an aërial-rooting species, and it is advisable to fasten the stems to stakes of Teak or some other hard wood, to which the clinging roots may attach themselves. The stakes should be of sufficient length to allow for 18 inches or so of growth. When potting is finished, the plants should be afforded a thorough watering at the roots, and be placed in a house having a southern aspect and humid atmosphere. They should be shaded for a few days, and, as soon as they have recovered from the effects of repotting, they may be exposed fully to the light, syringing them overhead frequently. When the season's growth is completed, water should be withheld gradually, and for a period of at least four months the plants should receive no water at the roots, but should be syringed occasionally to prevent the foliage and stems from shrivelling. These conditions should be maintained until flower-spikes are seen to be pushing from the stems, when the plants may again be subjected to moist conditions. Vanda Hookeriana and V. Miss Agnes Joachim should receive the same cultural treatment.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

WINTER-FLOWERING PELARGONIUMS.—No time should be lost in finally potting Pelargoniums intended for winter flowering. The plants may be placed out-of-doors in a position fully exposed to the sun and water afforded with care until the pots are full of roots. At this stage stimulants may be given sparingly, increasing it in strength as the season advances. Pinch out the points of the strongest growths and remove all flower-buds as soon as they appear.

SALVIA SPLENDENS.—Cuttings of Salvia which were rooted in March should now be ready for their final potting. Pots 7 inches or 8 inches in diameter will be large enough. A compost of good fibrous loam, leaf soil, old Mushroom bed manure, wood ashes, and sharp sand, forms an excellent rooting medium. See that the pots are clean and well drained, and pot the plants firmly. Examine the foliage for insect pests before potting, and dip the plants in an insecticide should there be the least evidence of red spider or aphis. When potted, move them to their summer quarters, preferably in some position which is sheltered from the sun during the hottest part of the day. The pots should be plunged in ashes.

PLUMBAGO ROSEA.—Old plants of Plumbago rosea which have been repotted must be given every encouragement to develop strong, healthy growth during the next few weeks. During hot weather the atmosphere should be kept moist by frequently damping the surfaces in the house. Syringe the foliage with rain-water in the morning and at closing time in the afternoon, and to keep the plants free from insect pests syringe them about once a fortnight with insecticide. Young plants which have been rooted this spring should be shifted when ready into their flowering pots, using a rich, open compost.

CHRYSANTHEMUMS. The work of transferring Chrysanthemums to their final pots should be accomplished with as little delay as possible when the plants are ready. Prepare sufficient soil to pot all the plants and place it under cover. The compost should consist chiefly of rich fibrous loam, leaf-soil, well-decomposed horse-manure, wood ashes, coarse sand, and crushed bones. The potting must be done very firmly, or the plants will always be in need of water. They may be arranged in their summer quarters when all the plants are potted, and, if possible, the pots should be partly plunged in ashes. This will entail a little more labour now, but it will save much labour later in watering. Recently-potted plants must be very carefully watered until the pots are again full of roots. They should be kept rather dry for the next few weeks. Syringe them two or three times a day, and damp between the plants frequently when the weather is very hot. It is a great saving of labour to plant a portion of the plants on a well-prepared piece of ground. Those which will be required chiefly for cutting may be treated in this manner.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

PROPAGATING FROM EYES.—A number of herbaceous plants may be readily increased from the stalks, which are cut into lengths containing four knots or eyes. These, if inserted into sandy soil in a cool frame to half their depth, profusely watered, shut up close, and shaded, will duly produce roots and shoots. The difficult Scottish Rocket is easy to propagate in this way, as well as Phloxes, Hollyhocks, and many others. The stems have to be neither too young nor yet too hard, and it is about this time of year that they are in proper condition for rooting.

ROSE CUTTINGS.—Roses propagated from cuttings inserted last autumn may be lifted and re-planted in turfy soil. They should be planted not nearly so deeply as they were at first, and roots that have outgrown others on the same plant should be cut back. Before filling in the soil completely, soak the ground with water, and an hour or so subsequently fill in the rest of the soil. In ten days or a fortnight afterwards apply a surface dressing of fertiliser, consisting of superphosphate and sulphate of ammonia, or soot, and other quick-acting manures, and hoe the surface deeply. The plants will make splendid material for autumn planting.

CLIMBING ROSES.—It conduces much to the ease of training Climbing Roses to tie or tack in rapid-growing young shoots as they develop. Certain varieties produce far more shoots than are needed to furnish the trellises for another year, and if not done earlier the less well-placed, though not necessarily all the weak shoots, should be at once cut out. It is possible to have too gross shoots, which ripen so badly as to be unable to withstand a severe winter. Hence the value of those so-called weaker shoots, which are more reliable.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

MULBERRIES. One of our Mulberry trees is producing an abundant crop of fruit. The tree is growing in cultivated ground that has been kept hoed, and is a good variety. The berries will be doubly valuable this coming season for preserving purposes, as there is a shortage of stone fruits, and they should prove useful for mixing with early ripened Gourds for preserves. Mulberry trees are frequently planted on lawns, and in such situations it will be well to water them when the fruit is swelling. The soil around such trees will need pricking up with a fork to enable water to penetrate more readily to the roots; where the trees are growing on mounds this attention is doubly needed.

QUINCES. Given a moist surrounding, the Quince needs but little attention at any time, and the trees will usually carry a full crop of fruit. It is seldom necessary, so far as my experience serves me, to have to thin the crop. Shoots that are growing too strongly should be stopped in good time, in order to preserve the balance of the tree. An occasional branch may need some support, as the foliage in itself is a considerable weight, and the branch may become very heavy after rains. I have known branches with a crop of fruit to add to the weight, to snap off after heavy rains. A forked stake makes a good support.

EARLY STRAWBERRIES.—This season we picked our first ripe Strawberries out-of-doors on June 13, which is an earlier date than ever before, and four days in advance of last year. The two varieties that gave ripe fruit on that date were King George V. and Keen's Seedling. I like the former decidedly better than Royal Sovereign; it does not make such luxuriant leafage, the fruit is more shapely, and of an excellent colour. Growers will do well to add this sort to their collection. Keen's Seedling still maintains its position as an early-cropping variety, but it needs a frequent change of soil. Laxton's Fillbasket is well named; our plants forming a bed of this variety are just swelling a heavy crop, and they are robust and healthy. This Strawberry stands a dry season remarkably well, whereas Waterloo, and others of that type, prefer a wet, dripping time, even when ripening their berries. Our first Alpine Strawberries are just about ripe, and the plants are bearing a very heavy crop. Those for the late autumn crop are still having the spikes removed and the ground about them kept clean.

NETTING BUSH FRUITS.—An effort should be made to get the work of netting of fruit bushes done as soon as possible. Birds will speedily take the first ripe Red Currants and Raspberries, and these early fruits are of the most value. Black Currants with us are a prodigious crop again this season, and although we have had big bud for some years, it makes but little difference to the crop. It pays to stop the shoots of Red and White Currants, but this work is often neglected, notwithstanding that it does not take much time. Aphis has not been troublesome to our bushes this season, and we have not been bothered with caterpillars. Those who have late Currants and Gooseberries on north walls will do well to keep them syringed occasionally and also watered at the roots. These late crops well repay for strict attention.

THE APIARY.

By CHLORIS

WATER.—When the queen is laying 2,000 to 3,000 eggs per day much water is required for the larvæ. At this time brooks are often becoming dry, so the bees are driven to seek their supplies round manure heaps—which is not hygienic. Therefore give them a good supply of clean water, as previously advised, and change it frequently.

HANDLING FRAMES.—The correct way to lift the frames is by the ends of the bars. Beginners are tempted to hold them by the metal ends, which may slip, and cause serious disaster. After lifting up a frame, for further examination, lower one end until the frame assumes a perpendicular position; give it a half-turn, lowering the other end, so that the comb is now wrong side up, and in a safe position for examination. Complete the inspection as soon as possible, but all movement must be firm, free from jarring, and without fussiness.

WARNING. When the bees are seen vigorously fanning at the entrance the bee-keeper should at once investigate the cause. It may be that the inmates require more air, which may be given by increasing the width of the entrance; in very hot weather it may be necessary to wedge up the whole of the brood-chamber off the floor-board. If this fails to allay the bees' uneasiness, disease should be suspected, and an examination of the brood-chamber made. Foul brood gives off an unpleasant odour; the cappings of the cells are broken and the brood dead and rotten. Earlier in the season the "fanners" may be at work on the alighting board because stores of food are fermenting.

TO GET BEES OUT OF TREES, WALLS AND OTHER PLACES. When a swarm takes refuge in a hollow wall or tree it may be got out as follows: Take a "Porter" bee escape and fasten it on a piece of wood large enough to cover the opening, and in the evening firmly fix it. All other openings should be closed with putty or similar material. Over the entrance, about 1 foot above, fix a skep containing a small quantity of bees and the queen; fix it firmly to a board and suspend all from a nail securely driven into the wall or tree. A small nucleus hive, containing a queen and bees will suit admirably. In a few days the whole of the bees will be hived. Each day openings should be searched for and stopped, so that all bees are forced out through the escape. An established stock in such a place would require four or five weeks to collect.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Potato Bloom.

Not for a good many years has there been such a show of Potato blossom as is to be seen at the present time. This precocious and luxuriant blossom, particularly on second earlies, is doubtless to be attributed to the remarkable season, and its influence on growth. The haulm grew away at a tremendous pace immediately the sunny weather succeeded the cold, damp spell, and the mass of blossom now showing is doubtless due to the rapid drying out of the light soils on which the Potatos here referred to are growing. Common sense would indicate that luxurious blossoming of the Potato must be incompatible with full tuber formation, and experiments confirm this view. Some year or two ago Messrs. Sutton and Sons carried out experiments on the effect of removing the blossoms from Potatos, and found that the removal made an appreciable difference—some 10 per cent., if we remember aright—to the crop. A difference of this magnitude—say, a ton to the acre—is by no means negligible in these times; but, unfortunately, the scarcity of labour will make it extremely difficult, and in many cases impossible, to apply the means of preventing this loss by systematic removal of the flower heads. Nevertheless, where this is possible it is manifestly well worth doing. To do it effectively, the flower-heads should be removed whilst they are in their young stage, for evidently after the flower-head is fully formed a good deal of the energy and material of the plant has already been wasted—so far as tuber-formation is concerned. With little practice it is easy to discover and pinch out the flower-buds as soon as they are visible at the points of the stems. It takes about half an hour to go over 10 rods thoroughly, and it is doubtful whether it is worth doing unless it is done quite thoroughly.

In the case of another crop—the Onion—the same tendency is manifest, and transplanted Onions, at all events those planted in light soils, are beginning to bolt. Where this is the case, no time should be lost in picking out the young flower-heads. If this is done, the crop may be in large measure saved; but if it is neglected, the bulbs will not swell.

The drought has proved unkind to transplanted plants in general. Maize reared under glass and put out in the open, even when it was lucky enough to be well watered in, is showing no tendency to "pick up." The leaves remain yellow, the plants are making little growth, and are in marked contrast with the rich green and vigorous stand of some plants. Indeed, it is evident that the vagaries of our climate make it impossible for the gardener ever to be sure which method—of direct sowing or transplanting—will give the better result; although it may be said that on the average transplanting of such crops as Onions and Maize is to be preferred. In the case of Tomatos out-of-doors we have no choice, and this year plants put out are standing still so far as growth is concerned, and, what is worse, making poor but exhausting attempts to flower.

These observations must be taken to apply to the lighter soils lacking substance and water-holding capacity. Such soils flatter the gardener in ordinary years, but in a year such as the present they reveal the nakedness of the land, and teach the valuable lesson that the fertility of the garden can only be established on a basis of rich humus provided by heavy and repeated applications of farmyard manure. Artificials alone in such light soils cannot suffice the plants. Their rôle is supplementary, and not fundamental. Their use is of inestimable value and assistance to the gardener, but they must be employed together with, and not in substitution of, organic manure.

THE LATE MR. R. HOOPER PEARSON.—The funeral of the late Mr. R. HOOPER PEARSON took place on Saturday, the 15th inst., at Putney Vale Cemetery, which is situated on the outskirts of the beautiful Wimbledon Common. The first portion of the burial service was read in St. Anne's Church, Wandsworth, and those present included Messrs. JAMES O'BRIEN, W. HALES, A. GROVES, W. J. BEAN, A. OSBORN, W. HONESS, A. DAWKINS, W. W. PETTIGREW, T. HUMPHREYS, T. LEWIS, and G. F. TINLEY (*Gardeners' Chronicle*). Several other horticulturists were present at the interment, including Mr. JAMES HUDSON, representing the Council of the Royal Horticultural Society; Messrs. G. J. INGRAM, secretary of the Gardeners' Royal Benevolent Institution, J. MCKERCHAR (Horticultural Club), J. HEAL, W. CUTHBERTSON, J. WEATHERS, A. C. BARTLETT and H. H. THOMAS.

AT the meeting of Directors of the "Gardeners' Chronicle, Ltd.," held on Wednesday last, a resolution was passed expressing the condolence of the Directors with Mrs. and Miss PEARSON in their bereavement, and placing on record their appreciation of the devoted services which Mr. PEARSON had rendered to the *Gardeners' Chronicle* during the 26 years he had been associated with the paper.

TRIBUTES FROM CORRESPONDENTS.

The news of the death of Mr. ROBERT HOOPER PEARSON will be received with feelings of sincere sympathy for his widow and daughter by a wide circle of gardeners and amateurs. He bore his prolonged illness with fortitude, but his end came all too soon. He had endeared himself to a very large circle of friends not only in the British Isles but far beyond the seas by his unostentatious, kind and courteous bearing; he was one of nature's gentlemen. As one who was privileged to enjoy his friendship for about thirty years I should like to be allowed to say how truly his character is portrayed in the leading article on p. 246 of last week's issue.

I write from a very intimate knowledge of his private life, which was very happy, pure, and lovable, and I can truly say that I never knew him do a mean thing, or suggest anything open to suspicion. His ideals were very high. He was always ready to help others in any good work, and to-day there are many who are grateful to him for his wise and encouraging counsel.

Horticultural journalism has lost an upright and valued member. In addition to possessing great literary gifts, he had a thoroughly practical knowledge of the various branches of gardening, which he turned to excellent use in his official capacity, in which sound judgment, tact and discretion were such valuable qualities. His life's interest was centred in the *Gardeners' Chronicle*, for which he laboured with untiring devotion, and on many occasions beyond his strength. *T. Humphreys, Birmingham.*

Although not unprepared for the death of Mr. R. HOOPER PEARSON, the news came as a great shock to me, one of his oldest London friends, for our acquaintance dated from the first week of his joining the staff of the *Gardeners' Chronicle*, since which time we have been the most intimate of friends.

It might be truly said that he lived for his work solely (for he really died in harness); a man of no particular hobby, if I may except his garden, his whole time and energetic nature were devoted to the furthering of his knowledge of the vegetable kingdom, and in transmitting that knowledge to the horticultural world through the medium of the *Gardeners' Chronicle* and of the books on gardening with which his name will long be associated.

In private life Mr. R. HOOPER PEARSON was seen at his best, a charming host, a loving father, and devoted husband. His home life was an ideal one, and in looking back on the many happy and instructive evenings spent in each other's company in our respective homes, I am cruelly reminded that I am deprived of his genial and kindly presence, and that I and my family, in common with his many friends, are left behind to mourn the loss of a true and steadfast friend. *J. F. McLeod*

It was with the deepest sorrow and regret I read in last week's *Gardeners' Chronicle* of the death of Mr. R. HOOPER PEARSON. The news came as a great surprise to me, for I did not know that he was ailing much, and a long promise to see him I regret was not fulfilled. What personal knowledge I have of Mr. PEARSON fully coincides with the remarks made in the leading article of last week's issue. It is many years since we first met, and I mourn the loss of a Cardiff Castle colleague, and likewise a widely esteemed and honoured horticulturist. *W. H. Clark.*

It was with great grief that I read of the death of the worthy R. HOOPER PEARSON. He was one of those men whom we all esteemed and admired, and the loss of him will be widely felt. *W. Botting Hemsley.*

HORTICULTURISTS AND MILITARY SERVICE.—So many Orders and Regulations have recently been issued that a short explanation of the present position may possibly be useful to nurserymen and others affected. There have recently been issued in particular two Orders which affect the point, namely, Order M.N.S.R. 63, dated May 23, 1918, and M.N.S.R. 53, dated June 6, 1918. The first-mentioned Order deals more especially with agriculturists, but it includes also market gardeners, fruit farmers, and men occupied in the wholesale food seed industry as experts, or as heads of departments of the business, and men occupied in forest tree nurseries as seed experts. This Order revokes as from June 11, 1918, all certificates of exemption

granted, on occupational grounds, to the classes of men to whom it applies, irrespective of age. The object of the Order is to bring all these men under the jurisdiction of the County Agricultural Executive Committees. These committees will have power to decide whether the men coming before them are either to join the Army or to remain in their present employment. As a matter of fact, it is intended to "comb out" under this Order at present only those men who are under the age of 31 and who are fit for general service (Medical Category A or Grade 1). This arrangement can, however, be altered at any time without further order. Consequently, men engaged in the occupations to which the Order applies should, irrespective of age, lose no time in communicating with their County Agricultural Executive Committee. If, however, these men have any personal or domestic reasons on which they seek to rely, they must bring these forward by making the usual application to the local Tribunal, and not to the County Agricultural Committees. The proper course is to lodge the application with the Clerk to the Tribunal, and to arrange with the Ministry of National Service, at or before the time of hearing, that this application should stand over generally, with leave to restore it for hearing, if the War Agricultural voucher should at any future time be withdrawn. Strictly speaking, these applications on personal grounds should have been lodged within four days from June 11, 1918, but the Ministry of National Service has power to allow application to be lodged at a later date if good grounds are shown. The other Order referred to above—M.N.S.R. 53—applies at present only to certain classes of nurserymen, namely:

Ref. No.	Classes or Description	Medical Grade or Category. Grade.	Category.	"Fourth" men affected by the Order.
139	Nurserymen wholly or mainly engaged in the cultivation of flowers and fruits under glass or flowers, ornamental trees and shrubs out of doors			
	(a) Foremen	1	A	1*-6
	(b) Carters, Lorrymen (horse or power)	1	A	1-5
	*(c) All other classes of workmen	1	A	1-5
		2	B1, C1	1-5

Application for exemption on the grounds of personal or domestic hardship may, by leave of the local Tribunal, be made, but, in that case, application must be lodged with the Clerk to the Tribunal within four days after June 22, when the existing exemption certificate on occupational grounds is revoked, namely, not later than June 26, 1918. No further application on the grounds of occupation, as distinct from domestic or personal hardship, can, however, be made. (Probably another Order will shortly be made on the same lines revoking the certificates of men of higher age and lower grades and categories than those mentioned in the Order.) It will be observed that this Order applies to fruits grown under glass, but the authorities do not contend that it applies to Tomato growers. Men over 41 who have become subject to military service under the recent Act must apply to the Local Tribunal within seven days from the date of their medical grading, but in practice the Tribunals are not accepting applications for any men below Grade II., and are directing them to keep back their applications until they receive their calling up notice. Men, however, who are dissatisfied with their medical grading must apply within *five* days to their Appeal Tribunal for a fresh medical examination. They would do well to be examined beforehand by their own medical attendant and to produce his certificate to the Army doctors. A private test for kidney trouble is especially desirable, as the Army doctors do not usually apply this.

* Subject to the limitation specified in Part II. of the schedule.

FLOWER FAIR IN TRAFALGAR SQUARE.—The Flower Fair mentioned in our issue of May 25, p. 213, was opened on Thursday last by the Duke and Duchess of PORTLAND. Other distinguished persons present included the ex-Queen AMÉLIE OF PORTUGAL and the Duchess of FIFE. A number of the large nursery firms are giving their support to the Fair, the proceeds of which are to be devoted to the maintenance of British ambulances for use on the French Front. Messrs. SUTTON AND SONS have put up a fine exhibit of vegetables in their best style; Messrs. E. WEBB AND SONS are showing stove and greenhouse plants; and Messrs. PIPERS have set up a miniature water garden and a fine group of flowering plants. Messrs. R. H. RAHE, LTD., are showing herbaceous plants; Messrs. BARR AND SONS, dwarf Japanese trees; Messrs. J. CHEAL AND SONS, Dahlias; Messrs. H. CANNELL AND SONS, Roses; Messrs. ALEX. DICKSON AND SONS, Roses and Sweet Peas; Messrs. WATERER, SONS AND CRISP, Roses; Mr. L. R. RUSSELL, trees and foliage plants; Messrs. R. WALLACE AND CO., herbaceous plants, Irises, and Water Lilies; and Messrs. WHITELEGG AND CO., Alpine plants of various kinds. In the centre of the square a stand has been erected for the sale of cut Orchid blooms, presided over each day by a different "saleswoman." Lady SEELY officiated in this position on the opening day. There are also a number of decorated barrows, filled with flowers which are being sold for the cause by voluntary lady helpers, and flower-sellers with baskets patrol the square. Military bands, lent for the occasion, help to enliven the proceedings. On Friday the show was opened by Lord BERESFORD, and, as was only fitting, on this day the band was that of the Royal Marines. The show is to remain open until the 26th inst., inclusive, and in case of wet weather most of the exhibits are under canvas. All the staging and covering has been lent by the Royal Horti

FIG. 111.—MILTONIA LADY VEITCH (reduced).
(See Notes in the Orchid Committee, p. 259.)

AWARD OF THE NEILL PRIZE.—The Neill Prize in Horticulture for the period 1916-1918 has been awarded by the Council of the Royal Caledonian Horticultural Society to Mr. JAMES WHITTON, Superintendent of Parks, Glasgow. The prize is in the gift of the Society, and is awarded every second year to a distinguished Scottish botanist or cultivator. Mr. WHITTON was born at the Gardens, Methven Castle, Perthshire, where his father was gardener for nearly 50 years. He began his training on June 1, 1865, at Thirlestane, Castle Lauder, the seat of the Earl of LAUDERDALE. In November, 1870, he

cultural Society, and Mr. W. E. BISSET designed the plan and carried out all the preliminary arrangements.

went as fourth journeyman to Glamis Castle, when the new gardens formed by the Earl of STRATHMORE were rising into fame through the wonderful Grapes grown and successfully shown by the gardener, Mr. GEORGE JOHNSTON. In the spring of 1872, when in his 21st year, Mr. WHITTON was promoted foreman, and remained in that position until November, 1876, when he was appointed gardener to JAMES HOULDSWORTH, Esq., of Coltness, Wishaw, and held that situation for 11 years. On the death of Mr. JOHNSTON he returned to Glamis, and was gardener there until March, 1893, when he was appointed Superintendent of Parks to the Corporation of Glasgow. During the 25 years he has served that Corporation the city has widely extended its boundaries and the number of parks has increased from six to twenty-six, whilst the smaller open spaces have correspondingly increased. In 1901 the Botanic Gardens were added to Mr WHITTON'S charge, and a year later, to the title of Superintendent of Parks, Curator of Botanic Gardens was added. When the Highland estate of Ardgoil, in Argyllshire, with an area of 14,740 acres, was presented to the city by Lord ROWALLAN, the supervision of it was added to Mr. WHITTON'S duties, although its administration does not fall to the Parks Committee. In 1913 the Council of the Royal Horticultural Society conferred on him the Victoria Medal of Honour, so that, with the award of the Neill Prize by the Royal Caledonian Horticultural Society, his efforts to maintain the tradition of Scottish gardening have been recognised by his many friends throughout the country. Last year, on the recommendation of the Lord Provost of Glasgow, he was made a Justice of the Peace for the County of the City of Glasgow.

IMPORTANCE OF THE POTATO CROP.—The lecture on "Potato Growing," announced in the last issue, was delivered by Mr. W. CUTHBERTSON in the Caxton Hall, Westminster, on Wednesday last, and was well attended. Mr. PROTHERO was unable to be present, and the chair was taken by Sir CHARLES BATHURST, M.P. The lecture was arranged by the Royal Horticultural Society, and several members of the Council of that Society, including the President, Lord GRENFELL, Lord LAMBOURNE, and the Rev. W. WILKS, were present on the platform. The chairman in his opening remarks stated that in consequence of the increasing drain upon our sugar stores it might become necessary later in the year to reduce the sugar ration of the people. He hoped it might long be postponed, but he would urge people to put by some of their ration, while, if it did take place, the Potato might relieve the position. It was no exaggeration to say that the bountiful crop of Potatos last season, coupled with unusual prescience on the part of the Government Department last spring, had saved us from famine. It was the Potato, above all crops, that had supplied the valuable bridge last winter and spring which enabled this country to span the critical stream of scarcity which might have carried us away. A fuller report of the proceedings will be published in the next issue.

RETIREMENT OF MR. JAMES WARD.—Mr. JAMES WARD has relinquished, owing to continued ill-health, the post of superintendent of the Norwich Public Parks, which he has filled since December, 1902. The spring and summer bedding in these parks have for years past borne eloquent testimony to the unfailing skill of a master horticulturist. Previous to taking up his duties at Norwich he was for some years head gardener and forester to Lord DUNLEATH.

LONDON STABLE MANURE.—Potato-growers in the Home Counties who are accustomed to use London stable manure in large quantities should buy early in view of the uncertainty of delivery, and clamp in the field where it is to be used next year. The clamp should be sheltered as much as possible from rain and sun, and it should be covered with a layer of earth. Summer storage of manure is undesirable as a general rule, but in this case it is probably the least risky course; it offers the advantage that the manure can be put into the land at the first ploughing in autumn.

WART DISEASE OF POTATOS.—The Food Production Department is prepared to arrange for the inspection of crops of Potatos of varieties immune to wart disease on application in writing from growers in England and Wales in districts regarded by the Department as suitable for the production of "seed." This arrangement will apply only to growers whose area under any one variety is not less than ½ acre. The object of the inspection is to secure, as far as possible, that pure "seed," true to type, shall be available for planting in 1919 in areas certified as infected with wart disease. Where, after inspection, the Department is satisfied that the stock is pure and the general condition of the crop satisfactory, a certificate to that effect may be issued to the grower.

WAR ITEM.—Mr. W. N. WINN, of the Royal Gardens, Kew, has received notification of the death from wounds of his son, Private J. N. WINN, Civil Service Rifles.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

POTENTILLA AMBIGUA (see p. 243).—I agree with Mr. S. Arnott about the beauty of Potentilla ambigua, and have known it for 38 years. Plants are still offered by some hardy plantsmen under its correct name. It is possible there are two forms in cultivation, including the plant known as P. dubia; one blooms from May to July, and the other in July and August. P. Tonguei is a garden-raised plant, growing 6 inches high. I have seen one answering to the colour and named P. Tonguei, more nearly three times that height, and the soil in which the plant was grown was not particularly fertile. Hybrids may sport, however. Regarding P. nitida, the third of the "real jewels" of the genus, I consider it does not act up to its reputation in the lowlands or plains, according to the accounts given of it by travellers in the Alps. It is neat and compact enough, but the colour is poor, and many Alpines deteriorate in this way when cultivated at low elevations. Besides P. ambigua, I would name two other Himalayan species that were quite common in large and small gardens during the seventies of last century, and are still quite plentiful, namely, P. nepalensis and P. argyrophylla atrosanguinea. *J. F.*

IRISES AND DISEASE (see pp. 235, 248).—May I express my deep indebtedness to Mr. W. R. Dykes for his timely and instructive remarks on this subject on p. 248. I started an Iris garden here last year under the advice of a well-known expert and grower, who approved the site and the plan of the garden, and arranged the grouping of the different varieties. The ground had been well cultivated previously, and the only suggestion the expert made was that I should give it a good dressing of lime, which I did. The plants, which consisted of very fine clumps, were nearly all put in their permanent quarters in September. The groups, as a rule, consisted of 12, 18, or 24 plants of each variety. I noticed that some of the leaves were brown, but attached no importance to it, for at that time I had not heard of an Iris disease. In the spring I noticed that the leaves of some varieties began to soften, turn first yellow, then brown, and would come away from the plants when pulled. This trouble started at the base of the leaves. For some weeks brown patches have been forming at the tips of the leaves, as well as here and there along the surface and edges; the spots increase in size, and eventually coalesce, the entire leaf becoming affected right down to the rhizome. I have been advised to try superphosphate of lime, and I have just got a supply of this fertiliser, so that the remarks of Mr. Dykes come to me at an opportune moment. *Cecil A. P. Osborne, The Grove, Old Catton, Norwich.*

SOCIETIES.

ROYAL HORTICULTURAL.

JUNE 18.—Although the fortnightly meeting at the London Scottish Drill Hall on Tuesday last was not quite so well attended as on recent occasions a fair number of visitors were present. The chief floral features were Sweet Peas, Delphiniums, Roses and Paeonies.

The Floral Committee recommended five Awards of Merit to novelties and 11 medals for collections.

The chairman, Mr. H. B. May, made a sympathetic reference to the death of Mr. R. Hooper Pearson, and spoke of his valued services to horticulture, and particularly in connection with the International Horticultural Exhibition, 1912, the Gardeners' Royal Benevolent Institution, the Horticultural Club, and the Floral Committee, of which Mr. Pearson had been a member for many years.

The Orchid Committee recommended two First-class Certificates, three Awards of Merit, and one Preliminary Commendation to novelties.

The Fruit and Vegetable Committee made no award.

Floral Committee.

Present: Messrs. H. B. May (in the chair), John Heal, G. Reuthe, J. W. Moorman, John Green, C. R. Fielder, J. F. McLeod, Arthur Turner, C. Dixon, John Dickson, E. F. Hazleton, W. P. Thomson, Chas. E. Pearson, Jas. Hudson, E. H. Jenkins, E. A. Bowles, L. Morris, W. J. Bean, J. T. Bennett-Poë, H. Cowley, W. Cuthbertson, Thos. Stevenson, Wm. Howe and R. C. Notcutt.

AWARDS OF MERIT.

Sweet Pea Ivorine.—A distinct grandiflora variety. The buds are pale yellow, but the large, fully expanded blooms are the colour of old ivory.

Sweet Pea Mrs. Hitchcock.—This beautiful flower is almost ideal in form and setting; its colour is best described as pale, creamy salmon-pink.

Sweet Pea Dobbie's Maroon.—A variety of a bright shade of maroon and of large size. It is a handsome flower, suitable alike for exhibition and for garden decoration. All three varieties were shown by Messrs. DOBBIE AND CO.

Sweet William Scarlet Beauty.—An exceptionally sturdy plant, bearing large, compact heads of fragrant, rich scarlet flowers. This most desirable flower was shown by Messrs. DOBBIE AND CO.

Delphinium Mrs. Baker.—A large, erect, and well-disposed spike of Oxford-blue flowers which have lavender centres. Shown by Mr. F. CRESSWELL, The Cottage, Hayes, Middlesex.

GROUPS.

A magnificent collection of border flowers, principally Delphiniums, herbaceous Paeonies and Irises, was arranged by Messrs. R. H. BATH, LTD., who were rewarded with a *Silver-gilt Flora Medal.*

Messrs. DOBBIE AND CO. received a *Silver-gilt Banksian Medal* for a collection of Sweet Peas which comprised "12 of the best standard varieties," together with the three sorts which received awards, and another novelty—Mrs. T. Jones, which is of uncommon bluish mauve colour and of much more than average merit.

A *Silver-gilt Banksian Medal* was awarded to Mr. L. R. RUSSELL for Caladiums, and small pot plants of Medinilla magnifica.

Silver Flora Medals were awarded to Messrs. KELWAY AND SONS for a very large collection of handsome Delphiniums; Mr. G. W. MILLER for a miscellaneous collection of border flowers, principally Delphiniums and garden Pinks in variety; and to Messrs. H. B. MAY AND SONS for their customary group of greenhouse Ferns, amongst which were interspersed pot plants of Hydrangeas, Fuchsias, Heliotropes, and Verbenas.

Silver Banksian Medals were awarded to Messrs. B. R. CANT AND SONS for a collection of cut Roses; to the Rev. J. H. PEMBERTON, for Roses, including Star of Persia, a new pillar variety bearing relatively large, rich yellow blooms; to Mr. JAMES DOUGLAS, for border

Carnations; and to Mr. G. REUTHE, for a collection of various shrubs and Alpines.

A *Bronze Banksian Medal* was awarded to Messrs. WM. CUTBUSH AND SONS for a group of Perpetual-flowering Carnations.

An interesting collection of Philadelphus was contributed by Mr. CHARLES TURNER, in which Norma, single white, Virginal and Boule d'Argent, doubles, were of great merit.

Mr. WALTER EASTEA showed Romeo, a new Wichuraiana seedling Rose with unusually double flower of dark crimson colour, and Little Meg, a dwarf Polyantha variety with pretty flowers.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart., in the chair; Messrs. Jas. O'Brien, hon. secretary; William Bolton, C. J. Lucas, Frederick J. Hanbury, W. H. White, S. W. Flory, J. Charlesworth, Chas. H. Curtis, E. R. Ashton, A. McBean, Frederick Sander, Pantia Ralli, J. Wilson Potter, Stuart Low, R. A. Rolfe, and R. Brooman-White.

AWARDS.

FIRST-CLASS CERTIFICATES.

Miltonia Lady Veitchiæ fig. 241, p. 221 *vexillaria Memoria C. D. Orcutt* × *Jules Hye de Crom*, from Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells.—A charming advance on the superb strain raised by the late Jules Hye de Crom, retaining all the good features of Miltonia Jules Hye de Crom (*Hyeana* × *vexillaria*), but with the rich colour of the mask on the lip intensified and rendered very conspicuous against the clear white ground. The plant bore five flowers of perfect shape; the sepals, petals, and lip are white with a shade of rose on the bases of the petals and a rich maroon triangular mark on the lip, changing to ruby-crimson towards the front portion, which bears short radiating lines of maroon colour.

Odontoglossum Primavera xanthotes × *crossum xanthotes* × *crispum xanthotes*, from Messrs. ARMSTRONG AND BROWN.—The best of the remarkable section of xanthotes crosses which is variable among the colour-characteristic pure white ground with varied brown-yellow markings. The plant bore a fine spike of seven large snow-white flowers, the sepals having in the middles clusters of brown spots, broken into broad petals in occasional stud of the same tint, and the lip a chrome-yellow base and crest with a white front.

AWARDS OF MERIT.

Odontioda crispum × *The Bishop*, from Mrs. M. F. OGILVIE, The Shrubbery, Oxford (gr. Mr. Bahnforth).—A home-raised seedling of typical white O. crispum with flowers 3½ inches wide and of fine substance; the blooms are pure white with dark-red markings around the yellow crest.

Odontioda Trubizond (*Odm. Fascinator* × *Odm. Charlesworthii*), from C. W. BIRD, Esq., Manor House, West Wickham (gr. Mr. Redden).—A dark, handsome hybrid. The plant bore a spike of nine flowers, which in size and shape were equal to those of the Odontoglossum parent. The sepals and petals are dark reddish claret with a very narrow silvery margin. The lip is white in front and blotched with red, the median area in front of the yellow crest being dark red.

Disa Itala (*Blackii* × *grandiflora*), from Messrs. FLORY AND BLACK, Slough.—A progressive step, bringing the hybrid Disas up to the standard of *D. grandiflora* in size and with the freeness of growth and flower inherent in the Veitchian race of hybrid Disas. The lateral sepals are broad and bright rosy-mauve in colour; the white inside is slightly tinged with rose on the upper surface, whilst the cream-white petals have dark markings.

PRELIMINARY COMMENDATION.

Odontoglossum Armstrongii (*crispum* × *Armstrongiæ*), from Messrs. ARMSTRONG AND BROWN.—The best of the violet-coloured strain raised at Orchidhurst. The large, broad petalled flower has overlapping segments, which are well arranged. The ground colour is white; two-thirds of the sepals is covered with large violet-blue blotches, the broad-fringed petals having similar-coloured markings. The lip is white with a dark violet blotch and markings around the yellow crest.

GROUPS.

Messrs. ARMSTRONG AND BROWN were awarded a Silver-gilt Flora Medal for an extensive and well-arranged group of new and rare hybrid Miltonias, Odontoglossums, and Odontiodas, with showy Cattleya species and other interesting Orchids.

Messrs. CHARLESWORTH AND CO., Haywards Heath, were awarded a Silver Flora Medal for a fine group of hybrid Miltonias arranged with hybrid Odontoglossums, Odontiodas, Laelio-Cattleyas, and interesting species.

Messrs. STUART LOW AND CO. were awarded a Silver Flora Medal for a well-arranged group of hybrid Orchids. The showiest were Laelio-Cattleya Pelens (L.-C. Dominiana × C. Enid) with large flowers and specially fine dark lip, and L.-C. Tenera gloriosa (L.-C. Martinettii × C. Mossiæ). A fine selection of Cattleya Mossiæ were included in this exhibit.

Fruit and Vegetable Committee.

Present: Messrs. W. Poupart, in the chair; J. C. Allgrove, J. G. Weston, A. R. Allan, Edwin Beckett, A. Billson, F. Perkins, Owen Thomas, E. A. Bunyard, and Rev. W. Wilks.

Three varieties of Cos Lettuce brought up from trial at Wisley were of first-rate quality, and should be valuable, as they have hearted well in this exceptionally dry season, and on a light soil. For the present these Lettuces are known only by their trial numbers.

A box of seedling Strawberries of great size but irregular shape was exhibited by the Marquis of SALISBURY (gr. Mr. H. Primett), Hatfield, Herts.

Messrs. LAXTON BROS. set up 9 boxes of ripe Strawberries, all of excellent appearance.

KEW GUILD.

JUNE 8.—The annual general meeting of the Kew Guild was held in the Lecture Room at the Royal Gardens, Kew, on Saturday, the 8th inst. There was a good attendance, and Mr. Charles H. Curtis, the retiring president, presided. Honorary membership was conferred upon [illegible] who are serving in the forces of their country, namely, Lieutenant Major Veitch and Mr. Wm. Cobb, after the application of Mr. W. N. Wright, seconded by Mr. Fraser, of Exeter, on June 7. Mr. Nye Bayman, who is interned in Germany, sent a postcard asking to remain a member of *The Kew Guild Journal*. The committee's actions to act as almoner in the case of distressed members. The accounts showed a balance of £15 to against £6 brought forward from the previous year. Mr. Curtis again brought forward his suggestion that a suitable memorial should be raised to the memory of Kewites who have lost their lives in the war, with a record of all Kewites who have served in His Majesty's Forces. It was agreed that such a memorial should be raised, and the matter was referred to the committee for full consideration, and the hope was expressed that such memorial should be placed in the Gardens at Kew.

SCOTTISH HORTICULTURAL.

JUNE 4.—The monthly meeting of this Association was held on this date, Mr. R. Fife, president, in the chair.

Mr. E. L. Scarlett, Sweethope, Midlothian, read a paper entitled "How the Engineer can Assist in Horticulture." Mr. Scarlett stated that the commercial grower was continually on the watch for new labour saving appliances. The engineer had come to our aid in many ways, as, for example, in the case of movable glasshouses, which could be moved from site to site and cover perhaps a dozen different crops in a season. A great field was open to him in the sterilisation of ground in the open, in which Mr. Scarlett thought he might take a hint from some of the devices used in the present war. A machine to project flame on the ground while travelling over it might be devised, and it would also get rid of weeds and all other pests and sterilise the soil at one operation. Other matters dealt with were suggestions as to heating by means of gas instead of coal; heating by hot air instead of water; the use of poison gases under glass for destroying insects; cold storage, and transport of produce.

CROPS AND STOCK ON THE HOME FARM.

POTATOS.

GENERALLY the growth of Potatos is regular, the haulm having come through the soil evenly and strongly. Directly the rows can be distinctly seen use the horse hoe to disturb the soil, even if there are no weeds. If the plants have a weak appearance give them a dressing of soot or one cwt. of sulphate of ammonia per acre, sprinkling it between the rows previous to earthing up. The crop has a promising appearance; the growth is sturdy, good in colour, and regular in the rows. Especially is this the case where new Scotch seed was planted. There are a few complaints about the irregularity of early varieties, probably attributable to rooks, which were troublesome as the plants showed through the soil.

In stiff soil, where the surface has been thoroughly moved between the rows, the Potatos do not appear to be feeling the drought as yet. Horse hoe between the rows, and hand-hoe between the plants. Where the plants appear to require aid in growth, sulphate of ammonia, at the rate of 1 cwt. per acre, should be scattered between the rows prior to earthing up. This should be done early, so as to disturb the roots between the rows as little as possible.

CHARLOCK.

Where spraying was done with copper sulphate (at the rate of 16 lbs. to 50 gallons of water, or 22 lbs. to the ordinary spraying barrel, which is sufficient for two acres), Charlock, if not killed, will be so checked that seed cannot be matured.

SWEDES.

In northern counties this crop is well on the way to growth. In the south, where Swedes are largely grown by sheep farmers for penning on the field as a substitute for the manure cart, sowing is not usually done before the middle or end of June. When sown earlier the plants are often attacked by mildew, or the flesh becomes hard or lacking in succulence, which for sheep and cows is the all important point.

Where there is a probable crop of Charlock in the soil, plough and harrow the surface and allow the Charlock to germinate; then, by harrowing promptly, the crop may be killed. After this if the weather is suitable, drill in the Swede seed. Often ploughed soil, with a fine filth, is all in favour of a good Swede plant, and is one of the best means of warding off an attack of Turnip fly.

For the benefit of lambs in spring, it is wise to sow Rape with the Swedes. Following a severe winter, the Swedes do not always produce tops at the right time, but the Rape is less liable to injury by frost. With a five coulter drill, one row of Rape should be sown to four rows of Swedes.

TRIFOLIUM.

This green crop is a valuable food for horses. Trifolium is sustaining, and, with a reduced ration of Oats, which usually occurs when the Trifolium comes in use in June, is especially valuable. By that time the plant is matured, the flower having faded. Only half the usual quantity of hay should be given at first, gradually reducing the hay as the Trifolium matures in its growth. To grow good Trifolium the soil should be fairly rich and clean. Often the seed is sown on stubble after Wheat and Oats, but in some seasons the corn cannot be cleared in time. Early sowing is important; the first or second week in August is a good time. A clean plot recently ploughed and summer fallowed, is a good soil to choose. The early red and late white varieties are the best. *E. Molyneux.*

Obituary.

WILLIAM BARRON. We regret to announce the death of Mr. William Barron, of the firm of Messrs. William Barron and Son, Ltd., landscape gardeners and nurserymen, Borrowash, Derby. Deceased was managing director of the above firm for a number of years, but owing to his health failing, he went to Australia in 1915, and resided there up to the time of his death.

MARKETS.

COVENT GARDEN, June 19.

Cut Flowers, &c.: Average Wholesale Prices

Roses, per doz blooms—	
- Frau Karl Druschki	2 0– 3 0
— Ladylove	3 0– 4 0
— Liberty	3 0– 4 0
— Madame Abel Chatenay	2 0– 3 0
— Niphetos	1 6– 2 6
— Richmond	2 6– 3 0
— Sunburst	2 0– 3 0
Stephanotis, per 72 sprs.	3 0– 3 6
Stock, English, per doz. bunches	10 0–15 0
Sweet Peas, various, per doz. bun	4 0– 8 0
Viola cornuta, per doz. bun	2 6– 3 0

REMARKS.—The market is well supplied with Cornflowers, Delphiniums, Gypsophila elegans, Irises, Poppies, Paeonies, Pinks, and large, white Daisies. Of the latter, the variety named Stella appears to be the most in demand. Several sorts of Sweet Peas are now offered for sale in excellent condition. Roses are also improving in quality; both indoor and outdoor blooms are offered in fairly large quantities. There is an increase in the supply of Gladiolus, both white and coloured. The cooler weather is more favourable for Irises, and the blooms now on sale are the best so far offered this season. Although Carnations are sufficient for the demand, prices remain firm for best quality blooms. Pyrethrums are finished for this season, but there is a good supply of white Stock.

In the Plant department decorative plants are receiving more attention. These include Erica, Crassula, Hydrangea, Marguerites, pink Spiraea, and pink Verbena.

Fruit: Average Wholesale Prices.

Lettuce, Cabbage and Cos per doz	0 6– 1 6
Mint, per doz. bun.	4 0– 6 0
Mushrooms, per lb.	2 0– 2 6
Mustard and Cress, per doz. punnets	1 0– 1 3
Onions, Egyptian, per cwt.	65 0 —
— spring, per doz. bun.	9 0–18 0
Parsley, per bus.	4 0 —
Parsnips, per bag	8 0–10 0
Peas, English, per bus.	10 0–12 0
Radishes, per doz. bunches	2 6– 3 6
Rhubarb, natural, per doz	8 0–12 0
Shallots, per lb.	1 0 —
Spinach, per bus.	6 0– 7 0
Sweeties, per bag	2 6– 4 0
Tomatos, per lb.	1 4– 1 6
Turnips, new, per doz bunches	4 0– 8 0
Vegetable Marrows, per doz.	12 0–14 0
Watercress, per doz	0 10–1 0

REMARKS.—In consequence of the absence of Strawberries an increased demand is anticipated for other fruits, which include Cherries, Nectarines, Melons, Figs, Peaches, Grapes (Black Hamburgh and Muscat of Alexandria), Red and Yellow Bananas, and Oranges. Asparagus is still available, and Peas and Broad Beans are plentiful. Forced Broad Beans are also fairly plentiful, but supplies of Cauliflowers are limited. The growers' consignments of Marrows, Mushrooms, and Cucumbers are about equal to the demand. *E. H. R., Covent Garden Market, June 19, 1918.*

ANSWERS TO CORRESPONDENTS.

APPLE EATEN BY MAGGOTS: *J. P.* The grubs are those of one of the Psyllas, which are frequently very destructive. Spray the trees at once with arsenate of lead, taking care to wet the young fruits. Do not let the spray material fall on Gooseberry or Currant trees, as it is very poisonous.

CUCUMBER FOLIAGE TURNING YELLOW: *E. B., Burwash.* The trouble may be due to a number of causes. The plants may have been somewhat starved before they were planted out, or received a check in some way, and, as the new leaves are of a healthy colour, this is probably the cause. Red spider will attack the undersides of the leaves, and this pest may also be responsible. The insects may easily be detected with a good glass, or even the naked eye. If red spider is the cause remove and burn the infested leaves and thoroughly syringe the underside of the remaining foliage with soft soap and water, promote a moist atmospheric condition, and never allow the plants to become dry at the roots. If you suspect the plants to be suffering from starvation apply a slight dusting of soot to the soil and keep the surface dressed with a little fresh compost consisting of half fibrous loam and half well-decayed leaf-soil.

GOOSEBERRIES DISEASED: *C. S. H.* The Gooseberries are attacked by American Gooseberry Mildew. Cut away all diseased shoots, and gather all affected berries and carefully burn them. Then spray the plants and the soil in which they are growing with liver of sulphur, 1 lb. in 32 gallons of water now, and 1 lb. in 24 gallons after July, with the addition of 1 to 1½ lb. of soft soap. Use nitrogenous manures sparingly. The best way to prevent a further attack next year will be to prune the trees early in October, taking care to remove all shoots showing the least trace of disease, and to gather up all fallen berries, and burn everything taken from the bushes, disinfecting any baskets used in collection with a solution of 1 lb. of copper sulphate to 20 gallons of water. American Gooseberry Mildew is a scheduled pest, and the Board of Agriculture should be notified of the outbreak.

MAGNOLIA SOULANGEANA: *W. H. Davies.* The best and easiest method of propagating Magnolia Soulangeana is by layering, which, in this country, is usually done in August or September. The layers take two years to root, and your failure in layering may be due to the fact that they have not been allowed sufficient time to form roots. The branches to be layered should be cleared of leaves, except for a few at the points, and be inserted in the ground 6 inches or so deep, bending the ends of the shoots as nearly at right angles as possible without breaking them. Making a tongue is not necessary when the stem is bent in this manner, which minimises the risk of breaking, the shoots being very brittle. When layered in this country during the months stated above the shoots have the maximum of pliability, being in the condition known as half-ripened. Cuttings of very soft wood inserted in May will root in a close case provided with bottom heat, but the results are none too satisfactory, and this method of propagation is not to be recommended for *M. Soulangeana*, though some other Magnolias root readily from soft cuttings. *M. Soulangeana* is a hybrid between *M. conspicua* (white) and *M. obovata* (purple), and was raised in France. Magnolia Alexandrina, *M. Norbertii*, *M. superba* and *M. rustica flore rubro*, are all hybrids of the same parentage, varying somewhat in the colouring of their flowers and period of blooming.

MANURE FOR VINES: *Vines.* Apply superphosphate of lime to your vines at the rate of 3 oz. per square yard, and if the fruit is not colouring add sulphate of ammonia, 1 oz. to the same space. As potash is difficult to obtain, a liberal amount of wood ash would be beneficial. No ammonia or nitrates should be applied after the berries commence to colour. The variety Madresfield Court is not suitable for growing with White Muscats; Black Alicante and Gros Maroc are the most suitable sorts for the purpose.

NAMES OF PLANTS: *N. M. B.* The flowering plant is Spiraea filipendula (Meadowsweet). We do not undertake to name varieties of Roses. Send them to a local Rose-grower, who can compare them with plants in his nursery. —*C. Wynne.* 1, Lychnis dioica flore pleno; 2, Saponaria ocymoides.—*W. Barnfather.* Glyceria rigida.—*A. Tomlinson.* Cupressus funebris.—*A. M.* 1, Asclepias curassavica; 2, Rubus deliciosus; 3, Polygonum Baldschuanicum; 4, not recognised.

RED SPOTS ON VINE LATERALS: *E. B.* The spots you describe are quite natural and are frequently to be found on vines grown both under glass and out-of-doors. Red spider generally makes its appearance on the underside of the leaves, causing them to turn brown. An excessive use of fire-heat, drought at the roots, and a dry atmosphere are the principal causes of red spider appearing. Mealy bug is one of the very worst pests of the vine, as it not only attacks the leaves, but when allowed to spread unchecked infests the bunches to such an extent as to render them unfit for use. This pest should be dealt with immediately the house is cleared of fruit, again in the winter, and again in the early spring. A sharp watch must be kept for mealy bug after the vines have started into growth and onwards until they are eradicated.

SWEET CORN AND PEAS: *M. M.* Whether or not it will be advisable for you to plant Sweet Corn between the rows of early Peas depends upon circumstances—chiefly the width apart of the rows of Peas, and the situation in which they are growing. Maize is a plant which, coming as it does from countries where the sunshine is much hotter and more continuous in summer than it is here, needs a position where it will be exposed to the maximum of sunshine if it is to develop any heads at all. Therefore, unless the Peas are very wide apart, or are to be cleared almost immediately, they will shade the Maize plants too much.

TENNIS COURT: *C. S.* A tennis court for the single game is 27 feet wide and 78 feet long; for the double game 36 feet wide and 78 feet long. The net is placed exactly across the middle of the shorter dimensions; the posts for supporting the net should be placed 3 feet beyond the sides. The service lines, marked in white lime, form a parallel line each side of the net, 21 feet from it. The net should be 3 feet high in the centre, and 3 feet 6 inches at the posts. The lawn used for the purpose should be perfectly level, and the grass well cut.

WHITE FLY ON CELERY: *M. M.* There are no flies on the leaves you sent us, but we suspect that the damage has been done by one of the species of Aleyrodes, commonly known as "White Fly." The best way of getting rid of the pest is to fumigate the frames in which the Celery is growing with a nicotine vaporising compound.

YEW TREE LOSING ITS LEAVES: *Taxus.* The Yew tree is evidently suffering from drought at the roots, and should be well watered, especially in the spring, just as growth commences. Somewhat the same appearance of the older foliage is caused by impoverishment of the soil due to the proximity of large, deciduous trees. The effect on the Yew is practically the same from either cause. For the present give the roots plenty of water, and in the autumn take out a trench around the tree, keeping well clear of the main roots, and replacing some of the old soil with turfy loam and well-rotted manure in equal parts. The Yew is a gross feeder, and can hardly be overfed in reason.

SPRAYING, LIFTING, AND STORING OF POTATOS.

ABOUT 200 persons were present at the lecture on Potato growing delivered under the auspices of the Royal Horticultural Society by Mr. W. Cuthbertson, in the Caxton Hall, Westminster, on Wednesday, the 19th inst. The title of the address was "Potato Growing, Spraying, Lifting and Storing." The chair was taken by Sir Charles Bathurst, M.P. He was supported on the platform by Field Marshal Lord Grenfell, President of the R.H.S., Lord Lambourne, Lady Margaret Boscawen, Major Belcher, the Director and Assistant Director of the Royal Botanic Gardens, Kew, Mr. Arthur W. Sutton, Mr. Leonard Sutton, and others.

The chairman, in introducing the lecturer, remarked that Germany had fed her civilian population to the extent of one-third with Potatos. By relying on the Potato that country had been enabled to carry on the war for at least a year longer than she would otherwise have been able to do. Being responsible for the supply and distribution of sugar in this country, and to a large extent for our Allies also, he took a special interest in the success and sufficiency of the Potato crop during the coming season. Owing to the increasing drain upon our sugar reserves, it might become necessary later to reduce the sugar ration of the people. He hoped this might be long postponed. At the same time he advised people to put by some of their sugar ration; while, if rationing had to come, the Potato might relieve the situation in so far as the necessary supply of carbo-hydrates in our food was concerned. It was no exaggeration to say that the bountiful crop of Potatos last year had saved us from famine. It was the Potato, above all other crops, that had enabled this country to bridge over the critical period of scarcity which might have carried us away.

Mr. Cuthbertson, in his opening remarks, stated that he hoped some at least of his audience were enjoying the first fruits of their labours on the strength of the advice he had given last year at the Mansion House. It was astonishing how quickly Potatos came to maturity, or rather a fit condition for eating. The most rapid growth he remembered was one season in South Hampshire, when sprouted sets of an early variety planted on a warm south border on Easter Monday were ready for use on Whit Monday. A writer from New Zealand stated that he had grown Midlothian Early from start to finish in 41 days. Some years ago he arranged with two growers in Penzance for them to grow a crop of Potatos in the open to be ready for the Temple Show in May. Although he had tried the experiment for three years he failed to get a collection ready for that exhibition by about a fortnight. In reference to spraying, he had pointed out that this operation was not a cure, but a preventive. It had been practised by the largest and most skilful growers for many years with splendid results, and he recommended the pamphlet on the subject issued by the Food Production Department.

Potato disease, he stated, first appears, as a rule, on crops growing in low-lying land, and later on those in elevated districts. He had conclusive evidence of this. The Potatos on one farm in the uplands of Lanarkshire, 600 to 800 feet above sea level, had never had disease. In the trials of his own firm there was no trace of disease except at one end of a large plot, where it not had been fixed to prevent the tops being damaged by westerly gales which cut through an opening in the hills. Just as far as the plots were sheltered there was a little disease. An open situation with a free circulation of air was therefore best for the Potato, which was a sun loving plant. He continued as follows:—

Field spraying is done by horse machines, but in gardens and allotments a knapsack sprayer, a hand sprayer, or syringe with an exceedingly fine rose may be used. The most convenient spraying specific is Burgundy mixture. Dry spraying is largely practised in Lincolnshire on thousands of acres with satisfactory results. The work is done when the leaves are damp, the workmen commencing about 3 o'clock in the evening and working all night into the effect of the dew has disappeared next morning. The sulphate of copper is said to adhere most satisfactorily to the Bordeaux when the latter is dusted on dry. It has been stated that dry spraying has not proved satisfactory in America.

When greed in difficulty developed it was possible to detect the "rogues" or plants inclined to some by the difference in the foliage or the colour of the flowers. Such rogues should be marked with a Bamboo cane, for removal, as also should any hearts affected with "Scab" or "Wackles," the latter disease causing the plants to wilt and become yellow and black at the base of the stem. The tubers of such plants should be lifted as soon as possible, and burned, as blackleg disease is carried in the tuber to the next generation. Tubers from plants affected with curl may be used for food, but on no account should they be retained as seed. For lifting Potatos "diggers" are now very common. In the Dunbar district of East Lothian, where the best Potatos in the world are grown, the Potato raising plough is the favourite instrument. A good working plough, properly set in a well-organised field, will make as good a job as a "digger" and lift 4 acres a day with the help of 24 gatherers, 3 or 4 carts, 4 pickers at the pits—in all between 30 and 40 people.

In gardens and allotments there is no better implement for lifting Potatos than the garden fork with three flat tines. After the lifted tubers have lain for an hour or two to dry those for table use should be gathered and pitted at once. Those intended for seed may be allowed to remain for a day or two to "sweat," if the weather is fine and frostless. Potatos for winter and spring use keep best in a good pit, clamp, grave, pie, or hog, names meaning the same thing. In the Lothians the pit is usually about 6 feet wide at the base, and the tubers are piled at an angle of 45° or thereabouts. They are covered with good straw to a depth of 6 inches and afterwards with soil to a depth of 6 to 9 inches. Firmly-packed soil keeps out frost better than loose soil. Danger arises from a frosty wind blowing for days on the side of a pit. In severe frosts more soil should be added on the windward side. Wheat or Barley straw is best for covering the Potatos, Oat straw being less valuable.

Small growers can keep Potatos quite well in a frost proof cellar in layers 18 to 24 inches deep. A few inches of straw should be placed between the walls and tubers, which should be kept quite dark by covering them with sacks. Potatos may also be stored in boxes or barrels in an empty room or attic, but should be well protected against frost. A garden shed is one of the very worst places for storing Potatos, owing to danger from a great and unexpected fall in the temperature.

In making a pit or clamp in small gardens select a site where there is no risk of water accumulating, and do not dig out the soil at the bottom. The base of the clamp should be 3 to 4 feet wide. In the event of straw being unprocurable, hay, Bracken, or old bags may be placed between the Potatos and the soil; even stout brown paper has been used with success. The soil for covering the sides of the clamp should be of a depth of at least 9 inches in exposed places. If rats are troublesome the tops of the vent pipes in the clamp should have a piece of wire netting squeezed into them. In many small gardens the pits are made in the shape of a wigwam or large bee skep.

The tubers should be dry and free from disease when stored; diseased tubers fed to animals should be well boiled. Tubers for seed should be boxed as soon as they are removed from the field, and this is especially necessary in the case of early varieties. It is generally more convenient to put seed of later varieties either by themselves or at the end of a big pit. Early in the New Year the contents of the pit should be turned over and re-pitted. This disturbance checks growth and enables decayed tubers to be removed.

The sprouts on greened tubers always seem to be shorter and stronger than those on sets not greened. Professor Seton, of the University Farm, Leeds, after a series of careful experiments, considered there was an increase of 1 ton 1 cwt. per acre from greened seed prepared in autumn over those prepared in spring. While sunlight causes bitterness, cold causes sweetness. Slight freezing changes some of the starch into sugar, but as the temperature rises the sugar is again re-converted into starch, and the Potato becomes palatable once more. I fear, however, that the greening power is weakened by this chilling process. Severe freezing ruins the Potato entirely. Investigations in the United States have shown that the freezing point of the Potato is between 26° and 28° F. In the United States storage houses are built for Potatos, in some cases to keep out the heat, in others the frost. Some of the American pits or storage cellars, are capable of holding 600 to 1,000 tons of tubers. In the Southern States the temperature is maintained at 34° to 38° F. by the brine system of refrigeration, the temperature being raised or lowered simply by varying the proportions of ice and salt in the tank which feeds the circulating coils.

In regard to grading, Mr. Cuthbertson stated that more attention was paid to this matter in the United States than in this country. In America selected tubers were wrapped in paper and boxed like Oranges.

For exhibition purposes the lecturer recommended that the Potato should be grown in specially prepared soil. The land should be carefully dug and broken down fine, leaf mould or sifted manure added and a dressing of artificial manure given in the drills at planting time, with, if available, some dry wood ash, all being stirred among the soil with a fork. Shapely 3 or 4 oz. tubers with two strong sprouts should be used as sets. The crop should be lifted carefully the day before the show, and the tubers

handled ordinary. The tubers for exhibition should be placed in a shallow box and covered with a sack to exclude the light, and they should be kept in the dark until they are on the exhibition table. The tubers should be carefully washed and all soil removed with a fine brush or cloth, and should be even in size, with the shallowest eyes. The "rose" ends with the eyes should face the judges, and the tubers should be kept as level as possible. Rubbing in transit may be prevented by wrapping each tuber *Journ. Ch. Acric.* on April 27, 1918, p. 173.

The best weight for exhibition was about 10½ ozs., judging by a dish of a flattish round variety he had once seen in a collection of 700 dishes.

In his concluding remarks Mr. Cuthbertson referred to the article on "The Chemical Life-History of the Potato" published in the *Gardeners' Chronicle* a few weeks ago.

Field-Marshal Lord Grenfell, who occupied the chair for the latter portion of the lecture, moved a cordial vote of thanks to Mr. Cuthbertson for his lecture. This was seconded by Mr. A. W. Sutton, who paid a tribute to the lecturer as one of his keenest competitors in the trade. He referred to the varieties of Potatos that had gone out of cultivation during the past 10 or 20 years. Only a few notable exceptions of those days were to be found in the lists of to-day. This showed the extreme importance of raising new varieties, as each year demonstrated the fact that the older sorts were becoming weaker in constitution and would eventually disappear, like their predecessors. The development of new varieties can only be secured at great expense, and he had paid as much as £750 to a Scottish specialist for a new variety the tubers of which were no larger than Hazel-nuts. It was impossible to say how many of such "seed" would turn out to be worth keeping. He mentioned this fact to show the enormous expense raisers of new seed Potatos incurred, and he hoped the Government would not impose any restrictions in regard to prices of seed Potatos that would be likely to interfere with this important work. His firm had undertaken the work of hybridising seed Potatos with the original Solanum Maglia, and the work had been going on for years, in the hope that something valuable would one day be obtained. The seed-grower should be encouraged to carry on this kind of work with Potatos, which was much more costly now than in former years.

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM HAMLET.

THE first flower of a hybrid between Odontoglossum Marietta var. Black Prince (Lambeauianum × Rolfeae) and O. crispum, named O. Hamlet (see fig. 112), is sent by Pantia Ralli, Esq., Ashtead Park, Surrey (Orchid grower, Mr. W. H. White). The flower is of good size, form and colour, the reverse side of the bloom being coloured almost as much as the face. The ground colour is white; the sepals are heavily blotched with confluent bands of purplish-red, the petals having similar markings, and both sepals and petals have white margins and tips. The lip is crimped and fringed, the centre being coloured dark purplish-red. The crest is yellow, with purple markings, which also appear on the upper side of the column. The influence of O. Harryanum, which was a primary and also a secondary ancestor, is shown in the crest and column, but, as with other complicated crosses, the identity of the less decided agents are difficult to detect. In this, as in most other hybrid Odontoglossums, the tendency is to enlarge the size and lessen the number of the coloured markings on the segments.

FIG. 112.—ODONTOGLOSSUM HAMLET (NAT. SIZE).

LAELIO CATTLEYA APOLLO.

A FINE flower of this pretty Laelio-Cattleya is sent by C. J. Lucas, Esq., Wainham Court, Horsham, who raised it between Cattleya Schroderae and Laelio-Cattleya warnhamensis (L. cinnabarina × C. Fraineri). The shape and size of the flower is derived from C. Schroderae, and the reddish-orange of L. cinnabarina, which usually asserts itself in the progeny in which it has taken a part, imparts a delicate reddish-apricot tint to the flower; the sepals and petals have a delicate veining of light rose colour. The well-rounded lip has a darker yellow disc, the front having a slight rose tint and veining as on the petals.

TREES AND SHRUBS.

THE CAMPERDOWN ELM.

FOR several years past I have noted a weeping Elm in several gardens in a western suburb of London, and also in Berkshire, although I have failed to locate the source from which the trees were supplied. It forms a narrow, umbrella-headed tree, with the compactness of the Kilmarnock Weeping Willow. The tree is Ulmus montana Camperdownii, and may be easily distinguished from U. m. pendula, of London, by its very broad leaves, lying above and hiding the branches, whereas those of U. m. pendula are narrower, and disposed beneath the branches, so that the latter are exposed all through the season while the tree is in full leaf. The Camperdown Elm takes up much less space than the older weeping form, and is, therefore, suitable for planting in small gardens and on lawns of limited dimensions. I have seen trees planted on either side of a narrow gateway, meeting above, and just pruned at the ends of the branches to prevent their blocking the way to the front door of the villa. The variety originated at Camperdown House, Dundee, where it was of some age 40 years ago, and prostrate on the ground amongst other Elms. I first saw the variety in a Forfarshire nursery in the nineties of last century, under the name of Lord Camperdown's Elm. *J. F.*

THE ALPINE GARDEN.

SAXIFRAGA COCHLEARIS.

THE two forms of Saxifraga cochlearis named major and minor are not new, but are too good to be neglected, and where the Silver Saxifragas are held in regard these varieties should find a place. In Mr. Reginald Farrer's book, *The Rock Garden* ("Present Day Gardening" series), there is a reference to S. cochlearis which should whet the desire of all garden lovers to possess this, one of the best of all the Saxifragas. All three forms are beautiful and all possess much the same character, with small rosettes of a pale blue-grey, and the spoon-shaped leaves all daintily notched and dusted with silver. Above the little silvery mound there rise lovely red-tinted stems bearing wonderfully big flowers of glistening, snowy purity. The type, S. cochlearis, is a gem. No less lovely, and perhaps finer, are the varieties major and minor. They share all the graces of the typical species, but major has bigger rosettes and leaves and larger flowers, while minor has a winsome charm which endears it to the true Alpine lover. Mr. Farrer tells us that it likes sun or shade, and that it grows well in calcareous or sandstone media. I grow S. cochlearis and its forms best in a moraine in full sun, with a modicum of lime mingled with the whinstone chips. This, I consider, increases the whiteness of the markings. *S. Arnott.*

SILENE VALLESIA.

THE free flowering Silene vallesia (see fig. 113) is very attractive on the rockery of the Botanic Garden, Cambridge. The species is not, I believe, common in gardens, but it is very distinct, and though not brightly coloured, is, in my opinion, one of the most desirable of all the Catchflies. It is robust, and spreads freely, but grows only about 5 inches high. The plant is pubescent and very glandular, so that the fingers are at once sticky if it is handled. The leaves are lanceolate and sharp-pointed, the stem leaves sessile, but the root leaves are narrowed into a petiole. The flowers are rather peculiarly coloured; the large tubular calyx, bulging above like a vase, is whitish, ribbed and veined with red; the corolla, with blind segments, their tips very soon incurved, is of lilac-rose colour, while below the colour is of brownish-red or brick-red. In Switzerland the plant is rare, growing only on some of the Southern Alps in Valois, on the Italian frontier. It is also native on the Alps of Savoy and Dauphiné, in Italy, in Bosnia and Montenegro. It is said to grow in stony places on silicious rocks, and is very local, but from the freedom of its growth here, on soil that must contain lime, I should expect that in cultivation it would grow in almost any kind of soil. The photograph from which the illustration is reproduced was taken by my foreman, Mr. F. G. Preston. *R. Irwin Lynch.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey

ONIONS.—Onions are growing freely, especially where the ground has been kept free from weeds, and frequently stirred. Continue to give occasional light dressings of old soot, which will improve the growth and otherwise help to ward off an attack of fly. This crop pays for a little extra attention, and if the bed can be given good waterings in the evening, or only syringed after a hot day, this treatment will increase the size of the bulbs, and generally improve the appearance of the bed.

BEET.—Thin the plants from sowings made in May to 6 inches apart, to obtain medium-sized roots. The latest sowing should be made by the end of this month, choosing a strong-growing variety. Keep the ground stirred between the rows to encourage free growth.

GENERAL WORK.—Pinch off the tops of Broad Beans as soon as they come into flower. Endeavour to keep the ground clean by constant hoeing, as it is useless to hoe up such weeds as Groundsel and Shepherd's Purse after they have been allowed to flower. They should be pulled up and burnt to prevent their seeding. Successional crops of Lettuce should be transplanted as soon as the young plants are large enough to handle, and if the weather should be dry, these and earlier crops should be well watered. The latest sowing of White Cos may now be made, and also a further sowing of Endive. Radishes and Mustard and Cress should be sown thinly broadcast in a fairly rich soil, choosing a border on the north side of a wall. Keep the soil moist, sowing fresh seed every ten days. Another small sowing of Dwarf Beans may be relied upon to provide good pods late in the autumn, provided there are no early frosts. Hasten with the transplanting of all spring-sown plants and all kinds of winter greens. Mulch the soil between Vegetable Marrows to retain the ground moisture, and also to economise labour. Heavy soils have cracked badly; fine material distributed among the rows of Carrots, Onions, Beet and other crops after the surface has been loosened, will prevent the ground from becoming hard, while much heavier mulching material may be freely used for the coarser-topped vegetables.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to MRS. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

POT FRUIT TREES.—Care should be taken that pot fruit trees from which the fruit has been gathered do not suffer for lack of moisture at the roots. Place the trees out of doors directly they have been cleared of their crops, plunging the pots up to the rims in ashes. Cherries should have a position out of the full glare of the midday sun. These will be followed by Plums, Peaches, Nectarines, and Apricots. The free admission of sunshine and air, daily attention to watering and syringing, with occasional light dustings of some concentrated manure, are necessary at the trees are to be in good condition for fruiting next year.

LATE VINES.—Let the bunches of late Grapes be severely thinned, and see that the crop left is not too heavy. Where the berries are swelling, maintain a moist atmosphere, and give every possible attention to the roots. If moisture is necessary, give strong manure water. Lateral growths should be kept pinched and gradually tied to the trellis.

MULCHING FRUIT BORDERS.—From now onwards the borders will require watering more frequently. Moisture will be conserved considerably if the borders are given a liberal surface dressing of well-decayed manure. The borders must be examined at regular intervals, and water given liberally when it is necessary. As the manurial properties of the mulchings become washed out, frequent applications of liquid manure should be given, especially to trees carrying heavy crops of fruit.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to SIR JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

CYPRIPEDIUM. Many species and hybrids of the strong-growing, warmth-loving Cypripediums, such as C. Rothschildianum, C. grande, C. Stonei and others of this section, after passing out of bloom, should be subjected to a short period of rest. After resting the plants should receive attention at the roots. Any that are pot bound may be shifted into larger pots. Remove, with a pointed stick, as much of the old compost as possible, without damaging the roots. Ordinary flower pots form the most suitable receptacles, filled to about one-half their depth with clean crocks. Pot firmly, keeping the base of the plant just below the rim of the pot. Other species that should be given attention in this respect, as soon as growth recommences, are C. callosum and its variety Sanderæ, C. Lawrenceanum with its varieties Hackbridgense and Hyeanum, C. Curtisii, and C. Maudiæ. These Orchids do not require such a retentive rooting medium as those that produce their flowers during the winter, nor is it needed in such quantity. The compost may consist of good fibrous peat, or Osmunda fibre two parts and one part Sphagnum moss. Both materials should be chopped up moderately short, adding a sprinkling of crushed crocks, the whole well mixed together. Pot each plant with moderate firmness. For a few weeks after repotting keep the surface of the compost just moist, but when the plants are re-established they may be afforded liberal supplies of moisture at the roots. At all times keep the plants on the shady side of the house. During the growing season, whenever the weather is bright and warm, these Cypripediums delight in having their foliage sprayed over with clear, soft, tepid water; but care should be taken with regard to such species as C. Stonei, C. Rothschildianum, C. grande and others of that section, that no water remains low down in the centre of the growths or axils of the leaves, as they are very liable to decay from this cause. If the plants have not been disturbed for a few years there will be a number of old growths that have flowered. One behind the lead or growing point is ample, and the others may be removed. If it is desired to increase the stock, the back growths, if placed in a warm, moist house or propagating frame, will often produce new shoots, when they may be potted to make fresh specimens. A better plan is to sever the rhizomes at intervals, a few weeks before it is intended to repot the plants. New breaks usually appear, and are sufficiently advanced for repotting at the same time as the front portion of the plant. Few Cypripediums prove more amenable to this form of propagation than the popular C. Maudiæ. Those of the leaf-growing Cypripediums, such as C. bellatulum and its variety, C. b. album, C. niveum, C. concolor and other hybrids that have no stalk, flowered, should also be repotted or resurfaced as is found necessary. These plants are best grown in pots or fairly deep pans provided with suitable materials for drainage purposes. A suitable compost for these Orchids consists of two parts good fibrous loam, broken up in lumps about the size of Walnuts, and one part peat, mixed freely with small pieces of mortar rubble. They are best grown in a position near the roof glass in the Cattleya or intermediate house.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

TRAINING AND PRUNING. Trees that were cut back as stocks and re-grafted with other varieties will need attention. In most instances it will be possible to remove the clay entirely. If this be still adhering firmly, moisten it, so as to get it away without injury to the grafts. Secure the young shoots upon bush or pyramid trees at once to small sticks. On walls these young growths may be secured better by string than by nailing; a few nails may be driven in and the string fixed to the nails. In the case of wall trees aim at keeping the leading shoot growing freely, and pinch the laterals. For bush and pyramid trees this is not so important an item to consider. See that no shoots develop from below the new graft so as to rob it of the sap. The shoots of newly-trained trees on walls should be secured either by tying or nailing, and the growths so trained as to secure a well-balanced tree. A free use can be made of the thumb and finger for stopping the growths. During hot weather keep all young trees well syringed, and also watered at the roots. Keep a sharp look-out for insect pests; if red spider threatens to be the troublesome it must be checked in good time. Secure the leading shoots by all means, but some light, twiggy growth, such as the prunings from Nut trees, may be used to secure the lateral shoots. If the sides be shrivelled, wired, tying will be expeditious. In the case of Peaches and Nectarines, stop the shoots not needed to furnish bare spaces. Some of the short, stubby growths may be retained as spurs. The breast-wood of Pears may this season be growing too freely with a shortage of fruit. It is rather soon yet to summer prune, but a check may be given by twisting or bending the shoot.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

STREPTOSOLEN JAMESONII.—Young plants of Streptosolen Jamesonii sometimes fail to flower through the growth not being sufficiently matured. Plants which have been propagated from cuttings should be kept growing during the next few weeks in a light, airy structure. Pot them when ready in rich, open compost. The strongest growths must be stopped occasionally to keep the plants shapely. Towards the end of summer move the plants out of doors in a sheltered situation to ripen their growth.

HUMEA ELEGANS.—These plants are developing their inflorescences, and require more liberal treatment in regard to watering and feeding. Diluted farmyard drainings and soot water may be given alternately. Admit plenty of air on all favourable occasions, and shade them only from bright sun until the flowers are fully developed, when they may be shaded during the greater part of the day. When the plants are in flower one or two of the best specimens should be selected for seeding. These should be placed by themselves until the seed is ripe. The heads should then be cut down and laid on sheets of paper. Young plants which have been raised from seed should be potted singly into 2½ inch pots. Plunge the pots in boxes of Coconut fibre and place them on a shelf in a cool house. Do not expose them to cold draughts, and shade them from the direct rays of the sun.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

AMARYLLIS BELLADONNA. Where Belladonna Lilies have grown into thick masses, and as soon as the foliage is decayed, they should be lifted, the flowering bulbs separated from the offsets, and either replanted at once or retained till August or September. The plants are extremely erratic here, and sometimes do not make foliage until the spring, which spoils them for flowering. When replanting give each a space of at least 12 inches and set them about 4 inches in depth in a compost consisting of turf and leaf mould to start them in. In other years a dressing of manure during winter will suffice the plants for that season.

THE ROCKERY.—Growth of the more luxuriant plants will now need restraining, and this is best effected by pulling portions away by hand. The early flowering plants will need their flower stems removed, and those that have become too thick to flower freely may either be transplanted after division, or parts cut out of them and the holes filled with compost. It may be necessary to surface dress ground containing low-growing plants with very fine compost as an aid to free rooting.

EDITORIAL NOTICE.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

APPOINTMENTS FOR JULY.

TUESDAY, JULY 2—
Roy. Hort. Soc. Coms. meet., Nat. Sweet Pea Soc. Ex., and Scot. Hort. Assoc. meet. at the Drill Hall, Buckingham Gate, Westminster.
TUESDAY, JULY 16—
Roy. Hort. Soc. Coms. meet. and Nat. Carnation Soc. Annual Ex., in the Drill Hall, Westminster.
THURSDAY, JULY 18—
Croydon Hort. Soc. Vegetable Ex. in Park Hill Recreation Ground, Croydon.
TUESDAY, JULY 23—
Southampton Royal Hort. Soc. show and Southern Counties Carnation Soc. Ann. Ex. at Southampton (2 days).
TUESDAY, JULY 30—
Roy. Hort. Soc. Coms. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 61°.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, June 27, 10 a.m.: Bar. 30.1. Temp. 63.0°. Weather—Sunny.

Rothamsted in 1918.

In war, as in peace, Rothamsted continues its patient investigation of problems connected with soils and manures in their relation with gardening and farming. Most of our readers are aware that this experimental station was founded by John Bennet Lawes, who began manurial experiments, first with plants in pots, and then in the field, in the year 1834. More systematic field experiments were begun in 1843, and, in the Broadbalk Fields, at least, these trials have been continued uninterruptedly up till now—a period of 75 successive years.

On the 18th inst., by the invitation of the Director, Dr. E. J. Russell, we were afforded opportunity of inspecting the work of the station and seeing the new laboratory which has been erected and equipped at a cost of about £26,000, to commemorate the centenary of the founders, Lawes and Gilbert. The new building is an imposing edifice, built of grey-red bricks. It stands on a slight eminence, and is a conspicuous feature from the trains running in and out of Harpenden Station, on the London side. The equipment consists of up-to-date chemical apparatus and physical appliances, and the building contains several specialised laboratories, one, named the James Mason laboratory, being devoted chiefly to researches in bacteriology. There is a special soil laboratory, and another for the study of entomology and protozoology, so far as these branches of science affect agricultural and horticultural problems.

Dr. E. J. Russell conducted us over the laboratories and the plots, and explained the aims and objects of the experiments that were being undertaken in the various departments.

At the present time the principal problems under consideration are the production of nitrogenous plant-foods, the better conservation and use of farmyard manure, the inoculation of the soil by beneficent bacteria, and the elimination or control of injurious insect pests, such as wireworms and cockchafers.

Owing to the great demand for nitrates by the Ministry of Munitions, the supply of this valuable plant food available for growers has become restricted. Experiments are being conducted with a view to increasing the nitrogen supply from straw. In the laboratory experiments the straw is chemically treated with a view not only to increasing the supplies of nitrogen, but also to prevent the waste of that material in ordinary stacks of farmyard manure.

Some of the more interesting experiments were those connected with the destruction of soil pests. The toxic effects of various substances are being investigated, and it has been found that when used alone, some are practically harmless to the pests, but when used in combination, they become highly effective. All this work, however, is at present in the initial stage, and it may be a considerable time before anything like a perfect soil insecticide that will perform its intended functions without injuring the soil or harming vegetable or animal life, is produced.

The famous Wheat experiments in the Broadbalk Field were examined with interest, this being the 75th successive year that the crops had been grown on precisely the same area, and mostly in precisely the same way. As might be expected, farmyard manure, and complete chemical manures, have always given the best results, while the incomplete fertilisers give poor results. If one thing more than another is proved by the Broadbalk Field experiments, it is that the same crop may be grown successfully on the same soil year after year. When Wheat has been grown continuously on the same plot for 75 years, and still yields practically the same quantity of straw and grain, without any signs of "sickness," it becomes necessary to modify our ideas on the rotation theory.

As with Wheat, so with Mangolds: farmyard manure and complete artificials naturally gave superior results, the former especially, as the soil is of a dryish, strong character.

The latest addition to the experimental work is electric culture. A small electrical installation has been fixed up, and the current is transmitted over the field from overhead wires. The results seem to be negative, so far at least as the eye could distinguish.

The question of soil inoculation by means of bacteria is also receiving attention, and in due course valuable discoveries may be looked for in this direction.

Under Dr. Russell's energetic and sure guidance this famous station has extended to a yet larger sphere of usefulness, and British agriculture and horticulture have reason to be proud of Rothamsted, not only for the historical part it has played in the peaceful past, but also for the strenuous part it is playing now in helping to solve problems arising out of the war.

BOTANICAL MAGAZINE.—The following plants are described and illustrated in Vol. XIV. of the *Botanical Magazine*, comprising the issues for April, May and June, 1918:—

PRIMULA ANISODORA, tab. 8,752.—A new Chinese species, discovered by Mr. GEORGE FORREST in Yunnan, at an altitude of about 11,000 feet above sea-level. The deep-red flowers are produced on a tall scape, which arises from the ovate, oblong, spathulate leaves, 6 to 8 inches long.

ODONTOCHILUS LANCEOLATUS, tab. 8,753.—This terrestrial Orchid, a native of the eastern Himalayas, bears a spike of greenish-yellow flowers with a prominent yellow lip. The stem is rosy-coloured, and bears handsome dark-green leaves, traversed with golden veins.

ZANTHOXYLUM PLANISPINUM, tab. 8,754.—A Rutaceous shrub, with spiny stem and trifoliate foliage; it is a native of Japan. The plant forms a bush about 6 feet high, and is very ornamental in autumn, when bearing a profusion of small red berries.

ERLANGEA AGGREGATA, tab. 8,755.—This plant is a native of Angola. It bears dense flower-heads of a bright mauve colour. The plant is likely to prove useful in gardens, as it flowers in mid-winter, and would make a suitable greenhouse subject.

MONADENIUM ERUBESCENS, tab. 8,756. — A Euphorbiaceous plant, with tuberous rootstock, from which arises the succulent stems, which bear at their apices inflorescences with cupular or bell-shaped bract-involucres having the appearance of stippling, like the Henbane.

MALUS SARGENTII, tab. 8,757.—This new Crab was discovered by Professor SARGENT in Japan, and is a close ally of M. Toringo. It makes an attractive garden tree, both when in flower and when laden with its bright red fruits.

ANGRAECUM GRACILIPES, tab. 8,758.—This is the plant described and illustrated in *Gard. Chron.* under the name of A. recurvum in the issue for November 29, 1913. The flowers are white, and have a broad, wedge-shaped lip.

RHODODENDRON SIDEROPHYLLUM, tab. 8,759.—One of the numerous new Rhododendrons recently introduced from China, and an ally of R. Davidsoniana. The flowers are a soft, lavender pink, and relatively large compared with the leaves, which are dull yellow on the under-side.

HOWEA BELMOREANA, tab. 8,760.—This Palm is well known in gardens in this country. It was described and illustrated in *Gard. Chron.*, July 19, 1890.

BULBOPHYLLUM SOCIALE, tab. 8,761.—This attractive Orchid bears a large, broad leaf, and a spike of orange flowers, which are striped with red and have a rosy-purple lip.

PRIMULA SYLVICOLA, tab. 8,762.—A Chinese species, bearing a tall inflorescence, with flowers in whorls, of a rose-purple colour. The species is closely allied to P. sino-molle.

MELICYTUS RAMIFLORUS, tab. 8,763.—A shrubby species, belonging to the Nat. Ord. Violaceae, and a native of New Zealand. The fruits are the most attractive feature, being about the size of Peas, and of a lavender shade. The female flowers are greenish, the male blossoms bright yellow.

WORSHIPFUL COMPANY OF GARDENERS.—The term of office of the Master of the Worshipful Company of Gardeners, Lieut.-Colonel JOSEPH FRANCIS, terminated on June 14, and at the installation Court held on that day the following resolution was unanimously passed:—"That the hearty congratulations and best wishes of the members of this Company be conveyed to their Past Master, Lieut.-Colonel JOSEPH FRANCIS, O.B.E., J.P.; that a Past Master's medal be presented to him, and that in recognition of his two years' service such medal be struck in gold." The Company presented Queen MARY, at Buckingham Palace, on the 22nd inst., with a bouquet

of Hermione Carnations, in commemoration of the seventh anniversary of the Coronation. Sir CHARLES WAKEFIELD, the new Master in succession to Lieut.-Colonel FRANCIS, made the presentation.

THE LATE MR. R. HOOPER PEARSON.—We are asked by Mrs and Miss ETHEL PEARSON to express their gratitude to the numerous friends who have sent letters of sympathy, and who contributed wreaths, on the occasion of Mr. PEARSON'S death. They much regret being unable at present to reply personally, but are none the less grateful for the kindness which has been shown to them.

—— Mr. CUTHBERTSON, in his lecture on Potatos at the Caxton Hall (see p. 261), made a feeling reference to the late Mr. HOOPER PEARSON. Proceeding to make a quotation from a recent leading article in our columns, he said "no one interested in horticulture could to-day mention the *Gardeners' Chronicle* without thinking of the very serious loss horticulture had sustained by the death last week of the Managing Editor of the paper. Mr. PEARSON was the personal friend of many present that afternoon, and his worth, ability and devotion to horticulture were known to and appreciated by a very wide circle at home and abroad, every member of which was a mourner that day."

BRITISH GARDENERS IN WAR-TIME.—Mr. W. F. GILES, manager of the seed production department of Messrs. SUTTON AND SONS, Reading, contributes in the form of a letter to the *Market Growers' Journal*, of America, an interesting article on "How British Gardeners are Carrying on." In the course of his letter Mr. GILES describes the steps which were taken at the outbreak of war by small cultivators to increase food production, and refers to the wonderful increase in allotments, and the no less remarkable increase in the area of garden ground under food crops. He notes that so far this large increase in production has had no adverse effect on the professional market gardener, but reserves his opinion as to whether, if the area now under cultivation is maintained, such an effect may become manifest after the war is over.

THE SOFT FRUIT CROP.—Estimates by the Board of Agriculture, based on careful inspection of the crops in the chief producing areas, indicate that the yields of soft fruits are considerably below the average. The causes of this unfortunate state of affairs are numerous. In the first place, the heavy crops of previous years are followed, as is always the case, by a lean year. In the second place, scarcity of labour has undoubtedly lowered the standard of cultivation, although it has, unfortunately, by no means reduced the cost. In the third place the area under such soft fruit as Strawberries has suffered a decrease owing partly to the pressure put on growers to increase their acreage of cereals and Potatos, and partly to the mistaken attitude of some county authorities in discouraging planting on the ground that fruit is a luxury. As we have pointed out more than once, what was a luxury in peace time has become a necessity now. In the fourth place, the spell of misty weather at the time of the setting of the crop prevented the distribution of pollen by wind or insect, and led to the incomplete pollination of the flowers. As a consequence many fruits of the Gooseberry, for instance though they began to swell, dropped before they were more than one-quarter size. Another contributory cause was perhaps neglect of spraying owing to labour shortage, resulting in the prevalence of insect and other pests. It is clear that every step that is possible of execution will have to be taken to encourage planting and cultivation of soft fruits.

FLOWER FAIR IN TRAFALGAR SQUARE.—The floral exhibition in Trafalgar Square held during the past week on behalf of the British Ambulances being used on the French Front has proved a great success. The exhibits were arranged in a very similar manner to those at the R.H.S. fortnightly shows—indeed, nearly all the firms represented are amongst the most frequent exhibitors at the Drill Hall. Water-Lilies from the R.H.S. Gardens, Wisley, were arranged in the water basins around the fountains. Considerable sums were raised by the British Carnation Society, the National Sweet Pea Society, and the National Rose Society, whose members give flowers for sale. Many of the nursery firms contributed 20 per cent. of the value of the goods sold, and in addition the gate-money helped to swell the total sum gained. Some firms gave the entire proceeds of their exhibits, which were sold at fancy prices. Messrs SUTTON AND SONS' magnificent collection of vegetables was disposed of by voluntary saleswomen, and it was entirely replenished on the Monday, the fresh consignment being again offered, and equally readily disposed of. In addition to this the firm contributed large numbers of cut blooms, which were sold at stalls at high prices. Messrs. ED. WEBB AND SON'S exhibits of fruit and vegetables were also sold for the benefit of the fund. Mention must be made of the gifts of Orchids, especially those of Messrs. SANDERS and CHARLESWORTH AND CO. An Odontoglossum hybrid was sold by Lady SUTTY for the sum of £100. Four thousand Orchids from Haywards Heath realised a shilling each and over, while 24 plants of Miltonia vexillaria sold for sums of from 5 to 8 guineas. Princess LOUISE, Duchess of Argyll, attended the Fair on the closing day, Wednesday, the 26th inst., when Mrs. LLOYD GEORGE presided at the stall of Roses contributed by Mr. ELISHA J. HICKS. At the auctions small bouquets of flowers fetched big prices; one of the most successful was conducted by Mr. ARTHUR COKE at Lady GARVAGH'S stall of blooms contributed by Queen ALEXANDRA. The Prime Minister arrived shortly before 4 o'clock, and the cheering was loud as he made his way to Mrs. LLOYD GEORGE'S stall. There he put his autograph on a card which was attached to a basket of Orchids, and sold for seven guineas. His signature on a mother-of-pearl shell also brought a substantial sum. It is expected that the total proceeds will amount to something like £10,000.

STRAWBERRIES.—The Strawberry crop for the remainder of the present season having been commandeered by the Government for the manufacture of jam for the troops, the public has been unable recently to purchase Strawberries at the shops. A concession has been made in releasing the Saturday consignments, for it was found that the jam makers were unable to deal with the fruits at the week-end. They were ordered to be sold to the public at a price not exceeding 9d. per lb. retail. The

FIG. 115.—SILENE ALTISSIMA FLOWERS PALE COLOUR, THE CALYX WHITISH, RIBBED AND VEINED WITH RED.

(See p. 266.)

NATIONAL SWEET PEA SOCIETY. The National Sweet Pea Society has arranged a special exhibition of Sweet Peas in conjunction with the R.H.S. meeting on Tuesday next, July 2. No money prizes will be given, but medals will be awarded to groups, and certificates to novelties.

ALLOTMENT STATISTICS.—Recently the Food Production Department asked the Local Authorities of England and Wales to make a return showing the total number of allotments prior to and since the outbreak of war. From the actual limited supply available to the public in London on the 22nd inst. was eagerly bought, in many cases at prices far exceeding the prescribed limit. Large quantities were also sold wholesale at Covent Garden Market to jam makers at the Government price of £40 a ton. It was stated that up to noon on Saturday, the 22nd inst., about 50,000 baskets of Strawberries had arrived at the market on that day.

figures received, and other inquiries of the Department concerning the increase of privately owned allotments, including those provided by railway companies), it is estimated that there are now in this country upwards of 1,400,000 allotments. The pre-war home was about 570,000 allotments; the number laid out since the commencement of war is approximately 830,000. Returns obtained from 69 of the 81 County Boroughs in England and Wales show that there were under 59,000 pre war allotments in these areas; whereas at present there are over 222,000 allotments, representing an increase of about 270 per cent. One hundred and thirty-two Town Councils reported just under 42,000 pre war allotments; now there are nearly 97,000 allotments in their areas—an increase of upwards of 130 per cent. In 253 Urban Districts there were 42,000 pre-war allotments, as compared with over 100,000 allotments now in cultivation—the latter figure representing an increase of about 140 per cent. The grand total of allotments in England and Wales at present covers an area of about 200,000 acres. Taking this figure—and estimating that 50 per cent. of each allotment is planted with Potatos (a conservative estimate)—there are 100,000 acres of Potatos on allotments. If those produce an average of 7 tons per acre (a moderate assumption for garden and allotment Potato crops), this means that the allotment holders of England and Wales will grow this year 700,000 tons of the most essential war-time crop practically on the spot where the produce is to be consumed.

SEED POTATOS FROM DEVONSHIRE.—On some of the high land in Devonshire, where the rainfall is rather high, Potatos are grown which give great promise of being first-rate for seed purposes. A trial is being carried out at the R.H.S. Gardens, Wisley, with Devonshire tubers against Scotch, Irish, and Lincolnshire ones. The results will be specially interesting to our Scotch friends, who have deservedly such a good reputation for seed Potatos.

SCARCITY OF CHERRIES.—The prices being paid for Cherry orchards this year are indicative of the scarcity of the fruits. At Sittingbourne, in a few favoured orchards, the fruits realised the unprecedented price of 50s. per bushel on the tree. The high prices are due to the shortage of all kinds of fruit, and the utilisation of Gooseberries, Strawberries and other soft fruits by the Government for the manufacture of jam for the troops. That the crop is much below the average is seen in the decreased value of Cherry orchards in Kent. An orchard of 20 acres at Barming, near Maidstone, sold for £240, against £715 last year; 28 acres at West Malling realised £150, against £660; 7 acres at East Malling and 4½ acres at Ditton sold for £2 and £3 respectively, against £125 and £166.

WAR ITEMS. We regret to announce that Captain E. L. BENBOW, M.C., attached R.A.F. (lieutenant R.F.A.), was killed in action on May 30. He was the son of Mr. J. BENBOW, of La Mortola Gardens, Ventimiglia, Italy. He went to France on February 2, 1915, and served with his battery for about 12 months. He afterwards served as observer with the Royal Flying Corps for eight months, then qualifying as a pilot; he was decorated by his Majesty the KING with the M.C. at the Investiture held in Hyde Park on June 2, 1917.

Information of the death of Mr. GORDON FARRIES, who has been missing for some time in France, has been received by his father, ex-Baillie FARRIES, Dumfries, his body having been found on the place where he fell, which was afterwards re-taken by the Allied troops. Mr. FARRIES served his apprenticeship with the firm of Messrs. JAMES SERVICE AND SONS, nurserymen and seedsmen, Maxwelltown, Dumfries. He afterwards entered the employment of Messrs. JAMES VEITCH AND SONS. Later he joined the garden staff at Kew, where he was employed at the time of enlistment.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

LONDON TREES.—Mr. Webster's interesting article on p. 251 deals chiefly with deciduous trees; but I can never understand why Quercus Ilex, the Evergreen Oak, is not sometimes planted instead of the eternal Plane. As the tree appears to grow well in the gardens of Buckingham Palace, it should do so elsewhere in London. Once it has become well established, it makes rapid growth, while on the ground of beauty it needs no justification; and it would give a sense of warmth to our winter streets. For example, how much more attractive the Mall would look in winter—particularly, I suppose, from the windows of Buckingham Palace—had Ilex been planted there instead of Plane! It would be a good step even now to interplant these Planes with Ilex, the Planes to be cut out when the others grew up. *Ashgn Trevor-Battye, Ashford Chace, Hampshire.*

—— Mr. Webster strikes a true note when he says that the "limit of numbers has long ago been reached," in planting Platanus acerifolia (London Plane) in the London area. In recent years I have noted with regret the removal of such beautiful and interesting trees as Robinia Pseudacacia Decaisneana, Ulmus stricta (Cornish Elm), and U. s. Wheatleyi (Guernsey or Jersey Elm), to make room for the London Plane, already only too plentiful in the district. I might add U. minor (East Anglian or Lock Elm), a small-leaved species of closely and finely branching habit that casts only a moderate shade. All the trees he mentions succeed well in the western suburbs, including a fine tree of Koelreuteria paniculata, which fruited as freely in 1911 as it does at Paris. This also applies to a tree at Kensington. I presume the cut-leaved Pyrus would refer to P. pinnatifida, which is not so common as it might be. The berries are larger, deeper red or crimson than those of the Mountain Ash, and the birds do not, as a rule, eat them so rapidly as those of the Mountain Ash. The London Plane does not thrive in Edinburgh or Glasgow, but I attribute that to the lower mean temperature rather than to the soil, though both causes may account for the slow growth. *J. F.*

CROPS AND STOCK ON THE HOME FARM.

HORSE BREEDING.

Now that horses are so scarce and dear, farmers should devote more attention to breeding them. The type of agricultural horse varies in counties and localities, and certain breeds are found best for particular soils, whether heavy or light. For the latter a lighter type of horse than the ordinary Shire is the most useful, especially where the animal is not required for heavy road work. On stiff, heavy land a thick-set, short-legged type of horse does the work more easily than a heavy animal, which is more favoured for road or town work. It is not so heavy in its tread on the land, which in some fields is an important point to observe. The Suffolk horse, commonly known as Suffolk "Punch," is an excellent type of general farm horse, being especially adapted for heavy land, as it has small feet and legs, as compared with the body. Shire horses will, no doubt, make more money when well bred for their special use heavy dray work in towns. A Shire horse, crossed with a half-bred, thick set mare, will produce a useful animal.

Where rough pastures exist, with abundance of water, especially water meadows, a good opportunity exists for breeding and rearing foals. With such convenience several foals are little trouble, and may prove a source of income, either for sale or for use on the farm. Horses from two and a half to three years old will do several days' work on the land weekly if put to light ploughing or harrowing along with an older, quieter horse. At first young horses should not be worked more than half a day at a time. Great care should be taken that the collar fits the shoulders accurately. Sore shoulders caused through a badly-fitting collar may do incalculable harm. Thorough quietness, consistent with firmness, are important items in breaking in young horses. Do not let the animal have a fright of any sort, remembering that the foundation for ill or good is being laid for all time. Avoid strain caused by pulling heavy loads, as this may ruin a horse in the shoulders, back, or legs, even if the trouble does not show at once.

It is not wise to breed from mares with such ills as greasy legs, ring or side bones. Remember the old saying, "like begets like." *E. Molyneux.*

Obituary.

ALEXANDER MACKENZIE.—We regret to announce the death of Mr. Alexander Mackenzie, for a long period manager of the nurseries of Messrs. Thomas Methven and Sons, Edinburgh. Mr. Mackenzie died on the 21st inst. in his 88th year. He commenced his gardening career at Belladrum, Inverness-shire, 70 years ago, and was successively engaged at Bowhill, Fullarton, and Archerfield. He was head gardener in 1854 at Ascraig, which he left in 1866, being shortly afterwards appointed manager of Messrs. Methven's Warriston Nurseries. He was for long treasurer of the Scottish Horticultural Association, and one of the regular speakers at its monthly meetings. He retired from active work some eight years ago.

ANSWERS TO CORRESPONDENTS.

BEE STINGS: *C. P.* If the application of a strong soda, or bicarbonate of soda, solution fails, the person in question ought never to have anything to do with the manipulation of bees. There are a few people to whom the sting of a bee is dangerous, or even fatal. As yet no one knows of a remedy that will meet such a case. In a few rare instances, to eat honey brings about swellings as if stung.

FIG TREE CASTING ITS FRUIT: *Brown.* The dropping of the Figs may be due to various causes, resulting in a sudden check at the most critical period of the fruit's growth. For example, a lower temperature than the trees are accustomed to might cause the fruit to drop, or the more liberal use of water in the house might have the same effect. A deficiency of lime in the soil might also be responsible, for the Fig needs lime, or lime phosphates. Too much moisture at the roots would likewise result in the border being cooler than usual, and cause a check to the tree. The foliage appears to be quite healthy. Give the roots a weak manurial stimulant in which phosphates are present in some form.

GLOXINIA "RUST": *C. C.* The "rust" on your Gloxinias would not appear to be due to any fungous disease, but may be caused by thrips, which are very troublesome on these plants. Syringing with clear water will keep the thrips in check. The damage might, alternatively, be due to condensation of moisture on the leaves, followed by hot sunshine, which would scald the foliage. Let the house be well ventilated, and keep the plants sturdy and strong; they are then less likely to be injured in the way you describe.

NAMES OF PLANTS: *C. T.* Lysimachia vulgaris.—*L. B. H.* Iris orientalis alba.—*W. A. H.* 1, Deutzia crenata; 2, Spiraea canescens; 3, Philadelphus Lewisii; 4, P. Lemoinei erectus; 5, Leycesteria formosa.—*J. K.* 1, Kalmia latifolia; 2, K. angustifolia var. rubra.

TOMATOS DISEASED: *J. W. W.* From your description of the foliage we suspect that the disease on your Tomatos is Black Rot, or Macrosporium Tomato. Remove and burn every fruit which shows the slightest symptom of disease, and spray the plants occasionally with potassium sulphide, especially when they are setting their fruits. Keep the ventilators open wide to prevent a damp, stagnant atmosphere, which would favour disease and weaken the plants.

NOTES FROM KEW.—VII.*

MY remarks last month on the behaviour of Irises at Kew have given rise to comment by letter as well as in the horticultural press. Mr Dykes believes in summer transplanting, Mr. Jenkins says it is wrong in principle and bad in practice. Mr Divers informs me that at Belvoir, where Irises of the Germanica breed are largely grown, he transplanted them at the same time as herbaceous perennials generally. Another correspondent maintains that they should not be disturbed at the root at it can be avoided. Sir Frederick Moore's observations are instructive. He writes:

"We find that by far the safest time to move Irises is just as the flowers fade; it is better than the spring. They are making new roots then, and stand pulling about. You will often find these Irises spreading out from the borders to the hard paths, and growing and flowering well. Irises growing on the top of a wall never get disease. These plants never flower more freely or look more effective than on top of a wall, and I think that is how we should grow Oncocyclus Irises. We find that plenty of old mortar rubbish from walls, burnt earth from the bonfire, and poor gravelly loam, with ample drainage, suits them, and we have a good show each year. Disease may appear on new plants for some time, and then it spreads to others. On our nursery border, the poorest, hottest, driest place we have, Irises are perfectly free from disease, and we get a splendid display of flowers. In cottage gardens where they are bordered by the wall of the house and path, and often overhung by the roof, they give good results, for the simple reason that they are left alone and often get dry, and the soil is poor. Have you ever noted them in small town gardens? The best Germanicas I think I ever saw were in King's Road, Chelsea. There was dust enough on the leaves to grow them in. It was a hot day, and the reflex heat from the house was overpowering, but the Irises enjoyed it."

In horticulture, as in other matters, we fight for our own views and practices. After all, experience teaches, and when men argue from their own we must respect their views. "There are fifty ways to town and rather more to heaven," wrote Matthew Arnold; so also there are many ways of growing most plants well, and what may be a help under one set of conditions may prove a hindrance under another. There was a time when Roses would not thrive at Kew; when Lilies were a hopeless failure, when even Rhododendrons were believed to require beds of expensive peat, in which they made a poor show. By giving heed to the natural conditions, and especially the soil at Kew these and other failures have been turned into successes. I am afraid we have been treating Irises too well. When the present beds were made for them, special soil (good Ealing loam) was provided. It would most likely have been better to plant them in the natural soil of the Gardens. Bulbous Irises are not in question. They, like Daffodils and Tulips, have a resting season, and transplanting is then performed.

Blue Penstemons are worth more attention than they have yet received. Years ago Sir Frederick Moore and I were together one Sunday morning in June in Messrs. Haage and Schmidt's nursery at Erfurt inspecting rare and beautiful plants, both tender and hardy. The subshrubby Penstemons were glorious, especially the blue-flowered species. They were a discovery. The best of them were P. azureus, P. heterophyllus, and P. cornubus (see fig. 2), the first-named of which is now beautiful in the rock garden at Kew, with flowers, some Gentian-blue, others a kind of blue shot-silk with crimson shading. The species is known to be variable and it includes Jaffrayanus, which Sir W. J. Hooker described as a species in 1858, when a figure of the plant was published in *Bot. Mag.* (t. 5,045). His prediction that it would become a "bedding out" plant has not been realised, although seeing that it continues to produce a succession of flowers in the summer months, and is a hardy perennial, it might well have done so. P. azureus is a short-lived plant and difficult, but when happy it is a gem. P. cornubus varies in colour from blue to white, and is a first-rate rock garden plant. Perhaps when the war is over and we have leisure for such work, the breeding of a race of blue Penstemons will be considered worth while by some expert.

Ononis is not a genus of specially horticultural value, but O. Billardieri has merit as a small leaved, prostrate shrub for the rock garden, as it grows only about a foot high and bears in June clusters of red and white flowers, or rather fruits, the persistent, wing like sepals, coloured crimson and white, being the attractive feature. A few yards off the plant might be taken for a dwarf Broom, but at close quarters one sees why the genus was formerly included in Polygonum, and why O. buxifolia, a near ally of O. Billardieri, was known as P. crispulum. The species vary in habit according to the amount of moisture and exposure they grow in; but they appear to be all mountain plants and genuine rock shrubs. O. Billardieri is quite happy in the rock garden at Kew.

Santolina pinnata is another pleasing little shrub, suitable for the rock garden, as it grows only about a foot high and forms a globe-shaped specimen. Its numerous erect, green stems, and leaves with terminal racemes of button-like, white flower heads, develop in midsummer. It is not unlike S. viridis, the Holy Flax, but that has yellow flower heads. Lavender Cotton, with white leaves and yellow flower heads, is another good plant for the rock garden, being, as Mr. Bean states in *Trees and Shrubs Hardy in the British Isles*, beautiful and interesting, and probably the whitest of all hardy shrubs.

As there is scarcely any summer bedding this year at Kew, flowers in July are less in evidence than formerly. There are, of course, the Roses which are a great feature, and to do them justice a special notice is needed. The beds in the neighbourhood of the Palm House are at their best at the time of writing, a few days of warm sunshine, following a spell of cold, showery weather, having brought them on nicely. The Rose garden near the Pagoda never looked better. It was a happy idea of the late Director, Sir W. T. Thiselton Dyer, to transform a rubbish hole into a garden for Roses of the semi-wild type. I know of

FIG. 1.—[illegible] IN THE WATER-LILY HOUSE, KEW.

* Previous articles appeared in the issues of January 19, February 9, March 9, April 6, May 18, and June 8.

no other garden like it; indeed, only a place like Kew could afford space for big groups of straggly Roses allowed to grow much their own way. The best varieties in flower now are the following: Rubin, Mrs. F. W. Flight, Diabolo, American Pillar, Helene, Seagull, Goldfinch, Blush Rambler, Silver Moon, Lyon Rambler, Edmond Proust, Jersey Beauty, Dorothy Jeavons, Psyche, and Rosa moschata and its double variety. The Rose Pergola near the Rock Garden is also good, though I have seen it better. Two varieties there worth special mention are Veilchenblau, known as Blue Rambler, and Flora Mitten, the former a queer shade of purple, which some folk do not admire; the latter, the best single flowered bunch Rose I know. The flowers are larger than American Pillar, and the petals, which are pale flesh pink and white, do not fall, so that the bunches are good for weeks. Kew obtained this plant from Miss Mitten, daughter of the late William Mitten, Hurstpierpoint, a great authority on Mosses, in whose garden it originated, whether by accident or design is not known. There is no other single Rose like it.

I was once asked for a list of hardy trees and shrubs that flower in July, and could only reply that there were very few. In the first place, a plant that fulfils its mission flowers in spring, grows and makes its fruit in summer, and ripens in autumn. Those garden plants that continue flowering more or less all through the summer have got off the line, or out of gear; they are as unnatural as the fowl which keeps on laying eggs. Domestication has changed their habits, to man's advantage, of course; and Roses, scarlet Pelargoniums, tuberous and semperflorens Begonias, Heliotropes, and similar plants that keep on flowering are our friends, not their own or nature's.

Here is a list of the trees and shrubs in flower in the first week in July: Robinia viscosa, Aesculus californica, a charming little white-flowered Chestnut; Catalpa speciosa, Magnolia glauca, Calycanthus, Philadelphus, the most decorative of all being the snow white double Virginal, of which there is a bed near the main gate (see fig. 3), Bouquet Blanc, and Voie Lactee being other good hybrids of Lemoine's raising; Escallonia langleyensis, E. Philippiana, Spartium junceum, Genista virgata, of which there are scores of big bushes at Kew, where it became naturalised many years ago; G. aetnensis, Cytisus nigricans, C. capitatus, Ligustrum sinense, also a conspicuous feature at Kew; Rhododendron viscosum, R. discolor, Clematis of sorts; Helianthemums, Cistuses, Osteomeles anthyllidifolia, Cotoneaster pannosa, C. salicifolia, C. Harroviana, Spiraea discolor, S. Menziesii, S. Veitchii, S. canescens, S. betulifolia, S. japonica vars., of which Mrs. Anthony Waterer is the best, Pyracantha crenulata yunnanensis, a charming shrub with bright green obovate leaves, the branches crowded with clusters of white Hawthorn-like flowers: Potentilla fruticosa, Colutea arborescens, Deutzia crenata, and Lonicera Heckrottii, the best of the Honeysuckles.

Two other showy trees worth mentioning in this connection are the Piltig Plane (Sycamore), which has long racemes of crimson keys, and is a good garden and park tree, and the variegated Magnolia acuminata, which is really attractive this year. Quite a good list, yet in a place like Kew they do not go far, and, were it not for the Roses, the gardens would look flowerless in July.

Water Lilies, both in the open and under glass, are in full bloom, the queen of them all being the Australian Nymphaea gigantea, with flowers 9 inches across (see fig. 1). It grows well and flowers freely in the tropical tanks here. Lilies proper are developing well, and there should be a good display in a week or two of L. sutchuenense, L. regale, L. japonicum, L. Henryi, L. pardalinum and others. L. giganteum, L. Martagon, L. Parryi, L. elegans, and L. croceum are already in flower. We find many Lilies can be easily propagated from home grown seeds, and plants thus raised thrive better than purchased bulbs. Does L. candidum ripen seed in this country? It is a failure at Kew.

The Potatos are a great success so far, and so are the Onions, though the maggot is in evidence, and we may have to own ourselves beaten by that most destructive pest. Pathologists have so far failed to find a remedy for it. The man who does will deserve a monument. *W. W.*

ORCHID NOTES AND GLEANINGS.

BRASSO CATTLEYA IMPERIALIS.

AT the meeting of the Orchid Committee of the Royal Horticultural Society on June 18 last, A. P. Umliffe, Esq., Woodford, Salisbury, showed a new cross named Imperialis between Cattleya Mossiae and Brasso-Cattleya Cliftonii (B. C. Digbyano Mossiae × C. Trianae), which should be recorded, although it failed to secure an award, for it had many excellent features which will doubtless develop satisfactorily. The flower, which is of the largest among Brasso-Cattleyas, is light rose-pink with a pale yellow centre to the fringed labellum, which has dark purple markings at the base. All the large-flowered Brasso-Cattleyas are beautiful, but there is some difficulty in distinguishing the different varieties on account of the predominance of light colours without sufficient darker markings to render identification certain.

ONCIDIUM LANCEANUM.

THIS Oncidium is reputed to be one of the most difficult of Orchids to cultivate for a number of years, and although some years ago good importations of it were received, but few specimens remain in cultivation. But it has been proved that when grown under proper conditions the plant does not necessarily decline in vigour. The cultivation of the plants in pots, placed on the staging, probably accounts for most of the losses, for the most vigorous plants are generally those grown in baskets and suspended from the roof-rafters of a warm, intermediate house.

Probably one of the finest plants in the country has been in the care of Mr. A. Taylor, gardener to Mrs. D'Arcy, Stanmore Hall, Stanmore, Middlesex, for many years; it flowers profusely every year, and is again sending up four strong, branched spikes, bearing flowers about two and a half inches in diameter, and very fragrant. The sepals and petals are honey-yellow, densely spotted with chocolate-brown; the handsome lip is rose-purple at the base, changing towards the front to rose-pink and blush-white. The species was first introduced from Surinam in 1834, and has since been collected in British Guiana, Trinidad and other localities.

The plant at Stanmore Hall has always been grown in a Teak-wood basket and suspended in an ordinary stove house with an even, but not high, temperature. Water is freely given the roots during the season of active growth, but the amount of moisture is restricted carefully in winter, although the compost is not allowed to become excessively dry for any lengthened period.

NOTICES OF BOOKS.

TIDAL LANDS.*

THIS work, the authors explain, is primarily concerned with those problems which underlie the maintenance of coastal and riparian lands, and, as a factor in such, the extent to which horticulture may be enlisted in the cause of conservation. So far as we are aware, it is the first English book treating of the preservation and reclamation of tidal lands both from a natural and an artificial standpoint. The engineer deals with such subjects as tidal and current data; the foreshore; tidal land and erosion and accretion works; State and local control; complementary problems; and authorities having powers and duties in relation to defence against the sea. Professor F. Oliver's part, relating to the biology and botany of the subject, will interest alike the student and the practician. For some years past he has devoted his vacations to the investigation of the vegetation of various sea shore and salt marsh districts, both at home and on the other side of the Channel, and his work will doubtless stimulate further activity in the same direction. Some idea of the scope of the part of the book may be gathered from the headings: The Evolution of Vegetation; The Fixation and Plant Protection of Sand Dunes; Plant Winning on Tidal Lands; Plants of the Shingle Beach; Plants of the Salt Marsh, etc.

In relation to nutrition, he states that an idea of the work done by the root in water absorption is obtained from the fact that Maize transpires on the average 2·4 lb. of water per stalk per diem. "This means that the crop planted in the ordinary way would take 244 tons of water from an acre of ground during the growing season, and this from a soil so dry that no mere pressure could express a drop of water from it."

It will come as a surprise to many that only thirty out of about 2,000 species of flowering plants in the British flora occur between tide limits, and only about a score of these are common. For the greater part these plants are succulent and smooth. Artemisia maritima and Obione portulacoides being exceptions. Grasses constitute the most important element in the vegetation of salt marshes. Among these Glyceria maritima, Festuca ovina var. rubra, and Triticum pungens are prominent. Considerable space is devoted to the consideration of the recent rapid spread of Spartina Townsendii on the Sussex, Hampshire and Dorset mud flats, where enormous areas have been covered by it within the last twenty years. The illustrations constitute an important feature of the work.

* *Tidal Lands. A Study of Shore Problems.* By Alfred E. Carey, M.Inst.C.E., and F. W. Oliver, F.R.S., Professor of Botany in University College, London. 8vo, with 29 plates and 52 illustrations in the text. (Blackie & Son, Ltd., 50, Old Bailey, London, E.C. 1918.) Price 12s. 6d.

TREES AND SHRUBS.

THE CATALPA IN LONDON.

THE Gray's Inn Catalpa, which is said to have been planted by Bacon, is usually regarded as the largest and oldest tree of its kind in London, and by some writers has been described as the finest specimen in this country. Though there is no wish to pull this historic tree from its proud position, yet recent research as to the history of the Catalpa and numerous measurements of existing specimens that have been taken by way of comparison, prove that the Gray's Inn tree is neither the largest nor the oldest in London. That Bacon, when appointed Master of the Walks at Gray's Inn in 1597, planted this Catalpa is open to grave doubt, the introduction of the tree not being recorded until 1726, or fully a century and a quarter later. There are two Catalpas of about equal size growing in the gardens at Gray's Inn, to one of which is attached a tablet with the following inscription:—"This Catalpa tree is said to have been planted by Francis Bacon, when Master of the Walks, Anno Domini, 1[illegible]." Owing to its recumbent mode of growth it is difficult to give exact measurements of the tree. The main stem, which is 9 inches in diameter, rests on the ground, and is partly buried in the soil for about 9 feet in length, after which it grows upwards. The girth at this point being 5 feet. As near as can be ascertained, the trunk girths 7 feet at ground level. The branches extend in a somewhat horizontal direction, and being of considerable length and weight are supported by a number of stout props, one of the branches which is buried in the soil having probably rooted. The total height of the tree is about 28 feet, and the branch spread 45 feet. The other Catalpa is growing on the opposite side of the garden, and is said to be a seedling from Bacon's tree, the branch spread of which extends to 60 feet, while the stem at ground level and at 5 feet girths 6 feet 9 inches and 5 feet 10 inches respectively. It is about 40 feet high, and in splendid health, but, like the parent tree, the heavy branches, four in number, take a somewhat recumbent and horizontal style of growth, and are supported by props. Both trees are growing on a mound, or more probably the soil has at some time been banked up around the leaning stems.

By way of comparison with the above, the following measurements of other Catalpa trees in the London area are interesting:—

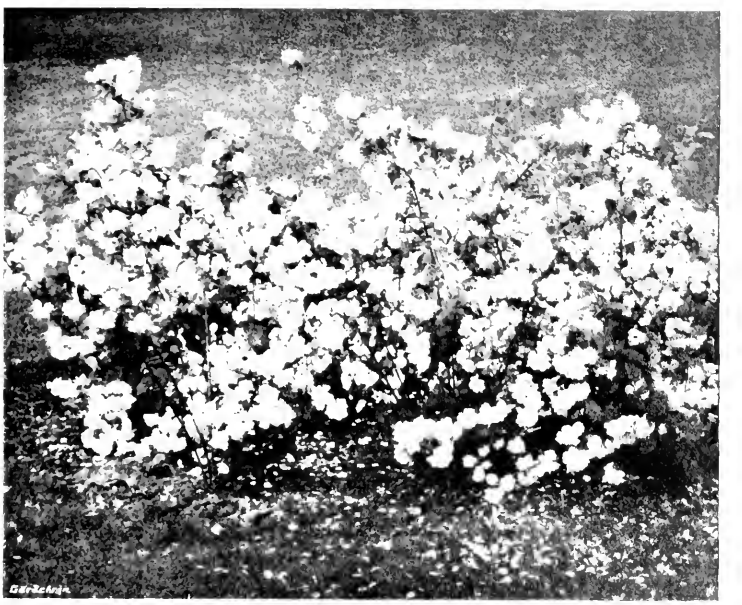
Holland House: The largest Catalpa girths 12 feet 1 inch at 2 feet, and 8 feet 10 inches at 5 feet from the ground; another is 7 feet 2 inches at 3 feet, the branch spread 51 feet.

Manchester Square Catalpa: Girth 7 feet 7 inches at 3 feet, the spread of branches extending to 54 feet.

Highbury Hill Catalpa: 7 feet 1 inch in girth at 3 feet; branch spread 42 feet.

Fulham Palace Catalpa: 5 feet 9 inches at 3 feet; branch spread 43 feet.

From the above it will be seen that the Holland House Catalpa is fully twice as big, and those at Manchester Square and Highbury Hill



[Photograph by E. J. Wallis.

FIG. 3.—PHILADELPHUS LEMOINEI VIRGINAL.

(See page 2.)

nearly half as large again as the Gray's Inn tree. As to the date of planting the Gray's Inn tree, reference to the history and introduction of the Catalpa shows that the tree was first described by Catesby in 1731, and again by the same botanist in his *Trees of North America* in 1767. The Catalpa is described and figured in the *Botanical Magazine*, 1808, where it is stated: "The plant has been long an inhabitant of our gardens, being introduced by the same botanist (Catesby) about the year 1728. It bears the smoke of large towns better than most trees; the largest specimen we have ever seen grows in the garden belonging to the Society of Gray's Inn." There is no reference to the Catalpa by any of the various writers on tree.

Gerard, Parkinson, Johnson or Evelyn, all of whose works were published after Bacon's death, and it is hardly likely that so remarkable a tree could have escaped the notice of all these botanists, especially at a time when particular interest was being taken in the introduction of new plants. Miller, in his *Dictionary of Gardening*, 1737, states that the Catalpa was brought

from the Bahama Islands by Mr. Catesby a few years before. It has been suggested that Raleigh, who visited Gray's Inn during Bacon's time, may have brought seed of the Catalpa from Virginia, but such a proposition is hardly tenable in face of the fact that the tree was only discovered a century later by the banks of the Mississippi

It will be evident from the above that the so-called Bacon's Catalpa is not the largest tree of its kind in this country, and as size denotes age, neither can it be considered as the oldest nor to have been planted by Bacon. *A. D. Webster.*

ON INCREASED FOOD PRODUCTION.

CELERY.

CELERY is one of the most important crops of the many vegetables that should be grown for next winter's supply. Celery may be eaten as a salad or cooked as a vegetable; for either purpose it is one of the most palatable dishes, and is said to be of much value medicinally. During the next six weeks Celery may be planted in any position of the garden, and it will succeed well in all soils, provided sufficient care is bestowed on its cultivation. There are three important rules which should be observed in growing Celery, (1) to select a good variety, (2) to give the roots a liberal supply of manure, and (3) an abundance of water during its period of growth. For late supplies the trenches should be of a moderate depth. The bottom soil should be broken with a fork, and the trench three-parts filled with half-decayed farmyard dung or London manure. The manure should be trodden firmly, the best of the excavated soil placed on it, broken down finely, and the plants carefully set with a garden trowel. One, two, or three rows of Celery may be grown in the same trench, the width of which is determined by the number of rows grown. Water the roots thoroughly and damp the plants overhead in the evenings during fine weather to favour quick growth. Every ten days a dusting of soot should be applied; this material helps to ward off attacks of the Celery fly, and at the same time is a fine stimulant

Copious supplies of manure-water should be applied to the roots during the growing season. Remove all side-shoots as they appear, and keep a sharp watch for the leaf-mining maggot, which should be picked off and destroyed.

Pink or red varieties should be chosen in preference to the white sorts for late supplies, as they are generally much more hardy; my favourite varieties are Aldenham Pink and Standard Bearer.

Wherever Celery is properly grown the land will be well prepared for almost any crop the following season and requires very little preparation. In addition to digging deeply for making the trenches, the whole of the soil between the latter will be needed for earthing up the plants, which means that the soil will be fully exposed to the beneficial influences of the weather. *Edwin Beckett.*

VEGETABLE MARROWS.

THE appeal from the Food Production Department for increased cultivation of Vegetable Marrows is sure of a sympathetic reception, for this is one of the most popular vegetables with the allotment cultivator. The elaborate mound which convention seems to decree must be made for the plants' accommodation is not at all essential to their well-being; in fact, under some conditions I am convinced it is a serious drawback, and militates against success. In the private garden, where the crops are under daily observation, and where copious waterings can be given as often as may be needed, plants on the mounds and raised beds do not suffer. But it should be remembered that, particularly when exposed to winds, the mounds, which are often composed chiefly of loose textured materials, dry out very rapidly. Frequently the worker can visit his plot at only weekly intervals, and the plants are likely to suffer from drought even when water is readily available. Another objection to the system of raising the soil is that unless unusual care is exercised, the rooting medium is far too loose and too easily penetrated by the roots, which results in soft and sappy growth and very few fruits. On heavy, low-lying soils, which are liable to flooding after rains, raised beds are necessary, but otherwise, if the usual procedure is reversed, and a pit is dug for the reception of the manure and soil, much greater success will be obtained. By this method the young plants may be more effectively screened from cold winds during the early summer.

The bush Marrow, which seems to be almost entirely ignored by professional gardeners, is deservedly popular with amateurs, who appreciate its non-rambling habit. It has been contended that bush Marrows are not so fruitful as the trailing sorts, but eight or nine fruits may easily be grown on a bush plant. Often the bush Marrow will produce its crop of fruits in quick succession and so have a short season, but this may be guarded against by gathering the fruits as soon as they are large enough for the table, and by setting out three or four plants according to requirements at fortnightly intervals. In point of quality the bush Marrow is equal to most of the long-fruited trailing sorts. It is, perhaps, inferior to a well-grown Custard Marrow, but the last-named is scarcely a profitable vegetable for the small garden in war time.

CLIMBING HARICOT BEANS

THAT under certain conditions Climbing Haricot Beans may be grown and ripened for winter use in this country was amply demonstrated by the examples shown at the R.H.S. meeting last autumn by Messrs. S. Bide and Sons. The bine was almost as long as that of the longest Scarlet Runner, and was amply furnished with goodly pods, packed with Beans. The primary object of the exhibit was to illustrate the vigour and fruitfulness of the seed, and it was scarcely to be expected that the precise cultural details afforded to the plants on view would be stated. But I feel that one could safely hazard that the method adopted was similar to that usual for Scarlet Runners in well-managed gardens. That is, seeds were sown under glass in the spring and the seedlings set out in their fruiting quarters some time towards the end of May, after having been properly hardened. Then, as with Scarlet Runners, supports would be provided, watering attended to during dry weather, and a stimulant given when the plants were in full bearing. If these Beans are worth growing, surely they are worth growing well, and should be given equal attention to that afforded the Scarlet Runner, but *J. F.*, in recounting his methods for this season (see p. 243), is very half-hearted. He anticipates and has prepared for failure. I am almost tempted to say he deserves it, for he has, like a timorous general, played for safety, and "planted the Beans between Potatos, so if they fail there will be no waste of ground." I am not a pessimist, but in such conditions I should expect the Beans to fail, if the Potatos succeed. Climbing Beans delight in, and respond to, warmth, moisture, and good living—so does the Potato. If these conditions, so necessary for the Beans, are present, what will be the result of the struggle for supremacy between the two vegetables? Flanked on both sides, the Beans are likely to be overwhelmed. There is yet another danger for the Beans so situated. The chief difficulty in their successful cultivation appears to be that of properly ripening the seeds. Yet, unless his Potatos are of an unusually late variety, the tubers must be dug, and in so doing the roots of the Beans mutilated, at a most critical time. *A. C. Bartlett.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey

TOMATOS.—Pay careful attention to tying and watering outdoor Tomatos which have started well, and are growing freely. When the crop is set the plants may be mulched and stimulants in liquid form can be safely applied. If the season is favourable their growth will be rapid, and the fruit will ripen from August to November.

TURNIPS.—A good breadth of Turnips should be sown during July to obtain roots for winter use. Chirk Castle Black Stone is one of the most hardy and valuable Turnips in cultivation for winter use. Those who like the yellow-fleshed varieties should grow Orange Jelly, which is also hardy and of good quality. Further sowings of Turnips may be made towards the end of the present month; the weather has much to do with the success of this crop, and it is not wise to depend on any one sowing. Dust the seedlings lightly at short intervals with lime, wood-ash and soot, and stir the ground on frequent occasions with the hoe. There is no necessity to reserve ground for Turnips; it should be possible to clear a good breadth of early and second early Potatos in time to sow Turnip seed. Chirk Castle is rarely injured when left in the open ground, and many only pull and store the roots when it is necessary to clear the land.

SCARLET RUNNER BEANS.—These Beans are growing rapidly with the hot sun, and are fast creeping up their supports, making large, healthy foliage. Prevent overcrowding by pinching out unnecessary growths; if extra large pods are required the clusters of fruit may be thinned also. Syringing the plants freely in the evenings of hot days will assist the plants in setting and swelling their pods.

PARSLEY.—A further sowing of Parsley may be made about this date, and in a warm situation. If a convenient position can be chosen to permit of a frame being placed over the plants during severe weather so much the better. If sowings were made as recommended, the seedlings properly treated, and given plenty of space, another sowing at this date is not often necessary. There is, however, always a regular demand for this most useful herb, and provision must be made by sowing in cold frames, or transplanting a sufficient number of plants in some position where protection can be afforded during severe weather.

SEAKALE.—Keep all surplus shoots removed from Seakale plants as they appear, leaving only the strongest. Frequent hoeings of the soil will be necessary during the summer to keep the ground clear of weeds. In dry weather give the plants a good dusting of soot between the rows, watering freely afterwards. Liberal waterings with diluted liquid manure will help the plants to form large crowns suitable for forcing.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

THUNIA.—Although the flowers of Thunia do not last for a long time after they are fully expanded, the plants are, nevertheless, very attractive. T. Marshalliae, T. Bensoniae, T. candidissima, T. Veitchiana and T. Brymeriana are species and hybrids well worth including in any collection. As these plants pass out of flower they should be removed to a cool, well-ventilated greenhouse, where the temperature does not fall below 55°. The stems and leaves should be exposed gradually to the full sunlight, so as to mature them thoroughly. The plants will need to be watered at the roots occasionally so long as the leaves remain green; when the colour begins to change to yellow, moisture should be gradually withheld. When exposed to the sunlight, and in a dry atmosphere, the plants are subject to attacks of red spider. To prevent this

they should be placed on their sides and syringed with insecticide, or soft soap dissolved in warm rain-water, allowing sufficient time for the leaves to dry before syringing the plants with clear water. Any plants that have failed to produce flowers, and of which the stems are growing too long, should have the points of the shoots pulled out, and the plants subjected to the same treatment as those that have bloomed. Thunias may be readily propagated during this month from the back pseudo-bulbs, which should be cut through at the joints into lengths of 4 to 6 inches. These should be inserted firmly in small, well-drained pots, using a rooting mixture of chopped Sphagnum-moss and coarse silver sand. Placed in a frame in the warmest house they will soon develop roots and top growth, when they may be potted singly in a rich compost. When growth is completed they should be rested in a manner similar to the older plants.

SOBRALIA.—As plants of Sobralia macrantha, S. xantholeuca, S. Lucasiana, and hybrids, pass out of flower, they should be repotted or resurfaced. As a general rule these plants are vigorous and easily grown, and produce a large number of thick, fleshy roots. When specimens have become so pot-bound as to cause them to be making smaller stems than those of previous years, they should be given increased rooting space. The pots or pans should be well drained, and the plants potted firmly in a mixture of good fibrous loam and peat or Osmunda fibre, with a sprinkling of crushed crocks added, to keep the whole porous. Specimens that do not require root disturbance may be assisted with diluted cow-manure water once or twice a week while they are growing freely. Sobralias are best grown in a house with an intermediate temperature. Plenty of water is required during the summer, and even in winter a moderate supply is required, as they have no definite resting season. Being subject to attacks of red spider they should be syringed freely on all favourable occasions; be careful to wet the undersides of the leaves. The foliage should also be sponged occasionally with insecticide.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

THINNING PEACHES AND NECTARINES.—Peach and Nectarine trees are, in many instances, bearing good crops. Lose no time in thinning the fruit now, leaving a margin for contingencies. The size of the fruit when matured should be considered, and late kinds need to be cropped more lightly than early ones.

STRAWBERRY LAYERING.—Where the forcing of Strawberries is being continued the first runners should be reserved for the purpose. After that give early attention to the propagation of the stock for planting out. Runners are not developing very kindly this season; a good watering will assist the plants to make freer growth. Nothing equals pot runners for planting out, and the use of potted plants will make all the difference between a light and a good crop the first season. Even if these have to be purchased, it is better than putting out ground runners. Those who can spare the room for growing a stock of plants one year in advance for the special purpose of securing early runners have a great advantage. In making these stock-beds the ground should be well trenched and manured, the rows made 4 feet apart, and the plants set 2 feet apart in the rows. When the runners are all taken the intervening spaces should be filled with the same varieties, and thus a good plantation will be secured for the following season. In doing this there need not be any waste of ground, for the intervening vacant spaces may be cropped with a quickly maturing vegetable at once. By this plan very early runners may be obtained, and these will be best for every purpose. Many trade growers plant Strawberries in this manner, and it amply repays them. When purchasing additional varieties give the order in good time, and thus secure an early delivery. Even if the same variety be grown it pays well to renew the stock every few years. This may not apply to all soils, but it does in the majority of cases.

EARLY-PLANTED FORCED STRAWBERRIES.—The plants should be well established, and any flower-spikes that appear may be allowed to develop. I have practised this system with Vicomtesse H. de Thury, and have secured a good return in ripe fruit by the end of August. The berries of Royal Sovereign ripen about a fortnight later under this method, and provide an excellent succession. A mulching of litter should be applied as soon as possible to keep the soil cool and moist. Watering is beneficial to these autumn-fruiting plants until the berries begin to colour. By that time they will be firmly established. Do not allow runners to develop and weaken the plants. Continue to damp the foliage overhead on warm days, in order to keep them moist during the late evening.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to MRS. DUNSTER, Keele Hall, Newcastle, Staffordshire.

TOMATOES.—Where Tomatoes are required in the autumn and winter, seed should be sown at once, as it is difficult to get the fruits to set if plants are raised after this date. Plants carrying heavy crops of fruit should be top-dressed with loam and decayed manure. Liquid manure or concentrated fertilisers may be used twice weekly. Keep all side growths removed, and, as the fruits ripen, shorten a little of the foliage, but not to the extent of denuding the plants. Admit air freely during the day, but reduce the amount of ventilation at night.

PEACHES AND NECTARINES. Give very careful attention to trees that are ripening their crops. The hottest season is still to come, and if the trees are to be kept free from insects the syringe should be used freely. No harm will result if the hose is brought into use to cleanse the growth and thoroughly moisten the borders; the syringe should then be used twice daily—early in the forenoon and late in the evening. Continuous syringings of clear water will rid the trees of red spider. All shoots that have served their purpose and are not required for next year's crop should be cut out to allow light and air to enter the tree, or the foliage will ripen prematurely, and the wood remain a pale green colour. Old-established trees from which heavy crops have been gathered will be benefited by light sprinklings of concentrated manure or diluted liquid manure, but feeding must not be done to excess or the trees will commence to make second growth when they should be resting. Let the ventilators remain open to their fullest extent day and night, and on no account should the trees lack moisture at the roots.

VINES. During very hot weather it is advisable to shade ripe Grapes to keep them in good condition. The berries of Black Hamburgh are liable to "shrivel" in hot sunshine after they have ripened. Only a light shading is necessary, such as is provided by scrim, garden netting, or a very thin coating of limewash to which a little salt has been added to make it more lasting. When the Grapes have been cut let the vines be syringed daily during hot weather. If the borders are dry give a good soaking of clear water, followed by liquid manure. Lateral shoots may be allowed to grow unchecked, but not to the extent of excluding the light and air from the vine. Where the crops are swelling examine the borders frequently, especially those outside, and, if the soil be dry, loosen the surface carefully with a fork. In the first instance apply clear water, and afterwards liquid manure. Examine bunches with swelling berries, thin crowded clusters, and remove small berries, which are apt to spoil the appearance of the bunch. The varieties Madresfield Court and Black Alicante need a little extra attention in this respect.

STRAWBERRIES. No time should be lost in layering runners for next year's forcing. Where strong "maidens" were planted out last August and the flower-buds removed this spring, the plants should now have excellent runners in abundance. Root them in pots 3 inches in diameter, filled with rich loam mixed with a little manure from a spent Mushroom-bed. The young plants will need spraying every evening in dry weather. The essential detail in securing good forcing plants is to commence the work of layering early, so that the crowns and the roots are thoroughly developed before the season is far advanced.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

LAPAGERIA.—This plant is now in active growth, and constant attention must be given to the training of the young shoots. Old-established plants will need plenty of stimulants. There is nothing better than manure-water from the farmyard. Failing this, some form of concentrated manure must be given. The plants should be vigorously syringed with rainwater twice a day during fine weather, and should aphis attack the young growths fumigate them at once.

LILIUM SPECIOSUM. This Lily will now be in need of plenty of stimulants, and if there is room for a little fresh soil on the surface of the pots it will be of great advantage. See that the growths are supported with stakes, and kept apart from each other. Plunge the pots up to their rims in ashes to keep the roots moist. Syringe the plants once a week to keep them free from aphis.

HYDRANGEA HORTENSIS. When this plant has finished flowering, the roots will require watering just as regularly now as they did when the flowers were developing. After flowering, each plant should be stood out-of-doors in a sheltered position and the pots plunged to the rims in ashes. When suitable cuttings are available they should be inserted singly in small pots filled with a sandy compost. Plunge the pots in a moderately warm hot-bed in a propagating frame and keep them shaded from bright sunshine until roots develop.

CAMPANULA PYRAMIDALIS. Seeds of the Chimney Campanula may be sown in boxes containing sandy soil and germinated in a cold frame, kept closed and shaded. Old plants are throwing up their flower spikes, and require plenty of water at the roots. Liquid manure and soot water should be used liberally at this stage, but feeding should be discontinued as the flowers develop. The flowering of the plants may be considerably retarded by placing them at the foot of a north wall.

IPOMŒA RUBRO-CŒRULEA.—If grown under the roof of a glasshouse having a minimum temperature of 50°, this plant will supply plenty of flowers during late autumn and winter. To raise plants for this purpose seeds may be sown now in 2½ inch pots, placing one seed in each pot. Plunge the pots in a hot bed in the propagating frame until the seedlings appear. Afterwards grow the plants in a house having moderate temperature, potting them on when necessary in a fairly rich compost. Syringe them with an insecticide occasionally as a precaution against attacks of red spider.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

BULBS IN GRASS. These will be so well matured that the grass can be mown with the scythe, and immediately afterwards with a lawn mower, which will leave the turf quite smooth. Should the bulbs have grown so thickly as to impair the production of flowers, now is the time to lift, to select the largest bulbs, and to replant. The surface should be heavily rolled subsequent to replanting. There is no better way of re-arranging the plants than to scatter the bulbs over the grass. Plant with a spade, pressing the soil apart, and inserting the bulbs before withdrawal.

ROOT-PRUNING. There is frequently need to thin shrubberies of plants too valuable to be disposed of by burning. It does not take long to root-prune any but very large specimens, and if done now it conduces much to their successful transplantation in autumn, by which time a mass of fibrous roots will have formed all round the cut parts. A spade thrust down to its full length all round the tree is all that is required to ensure this desirable end.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* EDITORS, 41, Wellington Street, Covent Garden, London. *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 62.5.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, July 4, 10 A.M.: Bar., 30.4; temp., 57.5°. Weather Sunny.

Fuel for Glasshouses.

In obtaining from the Controller of Coal Mines the announcement that an allowance of fuel for the heating of greenhouses and conservatories in private establishments will be forthcoming during the coming winter, the Royal Horticultural Society has done valuable service for horticulture. Gardeners will be grateful for the announcement, as it will enable them to lay plans for preserving their stocks of more valuable plants, which represent, in many cases, the work of generations of patient hybridisers or the toilful efforts of collectors in out-of-the-way parts of the world. National interests demand that there should be a saving of fuel in every direction, and many gardeners have anticipated this need by closing the majority of their stoke-holes and utilising their glass, wherever possible, for the raising of additional food crops. This economy of fuel will still be necessary, but growers will be able for the present, and until the fuel situation becomes more acute, and the continuation of supplies rendered impossible, to reckon on a sufficiency to preserve their exotics that are of exceptional value or interest. Should the supply fail entirely, growers must fall back on their own resources, and in large establishments substitutes may be forthcoming in the shape of rough timber and tree stumps sufficient to carry on. The basis of the allowances made by the Controller are as follows:—In respect to a single greenhouse attached to a dwelling-house there will be no allowance except under special circumstances. For Orchid houses, tropical houses, and others containing exotics of exceptional value or variety, or which are used for scientific purposes, an allowance based on two-thirds of the average normal consumption will be made. For ordinary ranges of greenhouses one-half of the average normal consumption will be allotted, conditional on the houses being used for the growing of vegetables or for forcing food plants for bedding out or other utilitarian purposes, and subject to certain houses being closed and the plants confined to a part only where the extent is considerable. In the case of ranges of greenhouses used for ordinary plants and flowers, one-quarter of the average normal consumption will be allowed, conditional upon the fuel being available in any month after meeting other requirements.

Whether the Coal Controller withdraws the concession tentatively granted or not, growers should begin to consider measures that will minimise the need for fuel, and obtain such substitutes as are forthcoming. The fullest use should be made of low houses and heated pits for wintering tender plants, and the larger structures devoted to the growing of early vegetables. It will be much easier to manage these small houses, and they will permit of the free use of blinds and garden mats in times of frost and cold winds.

Even tender plants will submit to relatively low temperatures, provided they are grown as hardy as possible in summer and autumn. The ventilators should be fully open on every favourable occasion, and the amount of atmospheric moisture reduced within the limits of safety. The forcing of fruits may be discontinued until happier times. Fruit trees in pots may be plunged in dry soil or a bed of ashes in a perfectly cold house and allowed to develop naturally. They will supply fruit in advance of the outdoor crops, and such trees will be benefited by the rest from hard forcing. The forcing of vineries and Peach houses may also be discontinued. Here again both the vines and the trees will be benefited by the rest.

The hot-water installations should be thoroughly overhauled some time in the near future, the flues cleaned and the dampers adjusted, for skilful regulation of the draught through the furnaces means economy in fuel consumption. Only an experienced hand should be entrusted with the management of the stoke-hole, for a clever stoker will get infinitely more heat from a ton of coals than one unused to the work.

It may be possible to obtain anthracite more readily than the soft coal used for ordinary stoves in dwellings. Those who have used this hard fuel know that it entails less work in stoking, and that one ton goes nearly as far as double the amount of coke. With regard to substitutes for coal and coke, the best is rough timber, including tree roots. Many estates will furnish both these materials, and the collecting of these and the lopping of decayed branches in avenues and woodlands will provide profitable work for the staff in spare time. Cinders from the house will burn freely in garden furnaces mixed with logs of wood, and should be saved for the purpose. Slack coal will burn freely with a good draught, and give excellent results if a base is built up of old tree roots. In some parts dried turf and peat are used as fuel, and these might be made use of in keeping in the fires during the daytime.

BATTLE-SCARRED WASTES.—Under the auspices of the Royal Horticultural Society's War Relief Committee, a lecture will be delivered by the Rev. ALBERT LEE, F.R.G.S., at the London Scottish Drill Hall, Westminster, on July 16, at 3 p.m. The lecture will be illustrated by lantern views. The title is "Battle-scarred Wastes," and is designed to show the havoc caused by the war throughout the fertile gardens, orchards and flower-growing regions of Northern France and Belgium.

THE BRITISH CARNATION SOCIETY AND THE TRAFALGAR SQUARE FLOWER FAIR.—The amount raised at the stall of the British Carnation Society at the recent Flower Fair in Trafalgar Square was £205 1s. 5d.

THE "SWEET PEA" AMBULANCE.—By contributions of money and the sales of Sweet Peas at the Flower Fair at Trafalgar Square, the National Sweet Pea Society was able to raise the sum of £180 2s. 6d. for British Ambulances in France. The sum of £200 is needed to provide one ambulance, and the majority of the Sweet Peas exhibited at the Drill Hall on the 2nd inst. were sold to make up the required amount. The ambulance will be named "The Sweet Pea."

ALLOTMENTS AT ALEXANDRA PARK.—Fifteen acres of land at Wood Green are being laid out to provide 225 war-time allotments. This land adjoins the race track at Alexandra Park, and is the property of the Alexandra Park Race Course Syndicate. The Syndicate has agreed to surrender the land for spade cultivation, and the Cadet Corps of the Women's Land Army will undertake the work after this year's hay crop has been harvested.

WOMEN FRUIT PICKERS.—Two thousand women will be engaged in fruit picking in the Wisbech district during the soft fruit season, under the auspices of the Women's Branch of the Food Production Department.

HONOUR FOR SIR ARTHUR H. LEE.—In recognition of his conspicuous public services as Director-General of Food Production, Col. Sir ARTHUR H. LEE, M.P., has been raised to the peerage. It will be remembered that in 1917 the new peer presented the Chequers estate to the nation for use as the official country residence of British Prime Ministers.

A FRENCH GARDENERS' ASSOCIATION.—An association of professional gardeners has recently been formed at Geneva, with a comprehensive programme of improvements to be applied where possible to the wages and status of gardeners employed in private houses.

NEW ROSES AT BAGATELLE.—We have received a report on the new Roses sent to the Rose gardens at Bagatelle, near Paris, for trial, and it is satisfactory to learn that both the Gold Medals have been awarded to Roses sent from English-speaking countries — one to Messrs. HOWARD AND SMITH, of Los Angeles, California, for their new variety, Los Angeles, and the other to Messrs. WILLIAM PAUL AND SONS, LTD., of Waltham Cross, for Paul's Scarlet Climber. Los Angeles is the result of a cross between Lyon Rose and Mme. Segond Weber. It has the beautiful colouring of Lyon Rose, without its capriciousness, flowering all through the season. Paul's Scarlet Climber was described and illustrated in *Gard. Chron.*, May 29, 1915.

PLATYCODON GRANDIFLORUM (see fig. 4).—This handsome, tuberous-rooted perennial of the Campanula family is known as the "Chinese Bell-flower." The genus is monotypic, but the solitary species is very variable, and the several distinct forms may be accounted for by the wide distribution of the plant throughout Northern Asia, China and Japan. It is an excellent border plant, easily raised from seeds, and grows well in light, rich soil. The flowers are large, and open more widely than in most Campanulas: they develop on the upper parts of the stem, and in the axils of the upper leaves. Though introduced into cultivation more than one hundred years ago, Platycodon grandiflorum is not so plentiful in gardens as its merits deserve. This may be due to its dislike of transplanting, as unless the long roots are handled very carefully they get broken, and the plant bleeds profusely, causing it to rot and die. Old established plants come up year after year, increase in size, and flower freely during the summer. The typical plant grows about 2 feet high, has glaucous leaves and rich blue flowers netted with lines of a deeper shade. There is a pure white variety called Album, and one known as grandiflorum which flower later in the autumn. The latter is taller than the type, with smaller but more numerous blue flowers. The best of all is the variety Mariesii, illustrated on fig. 4; this is a dwarf form, with large, rich blue flowers on stems about 1 foot high. The dense, sturdy habit makes the plant exceedingly attractive on a rocky bank or in the rock garden. There is also a white-flowered form of Mariesii in cultivation.

ONE HUNDRED AND FIFTY GUINEAS FOR A ROSE BLOOM.—The Rose Lover, Mr. ANSELL CHARLTON, paid £157 10s. at the Trafalgar Square Flower Fair, 1918, for a bloom of Charles E. Shea. Mr. ELISHA J. HICKS stood next which Mr. LLOYD GEORGE presided.

PROPOSED FLORAL MEMORIAL TO THE LATE MR. J. HARRISON DICK. The American Dahlia Society has decided to offer a special prize for the best new long-stemmed, seedling Dahlia exhibited at its autumn show this year, and if the successful variety is of sufficient merit it will be named J. Harrison Dick, in memory of the late secretary.

A FLORIFEROUS RHODODENDRON.—A plant of Rhododendron Mrs. G. H. SHAW, in Mr. H. SHAW'S garden at Addlestone, Surrey, has produced twenty large trusses on the same branch, the whole forming a gigantic inflorescence, which when viewed from above, had the appearance of a perfect wreath of blossom. The twelve largest trusses forming the inflorescence were disposed round the main stem with precise regularity, and were of uniform length. Mr. SHAWS informs us that Rhododendrons have flowered unusually well with him this season.

FREAM MEMORIAL PRIZE. The Board of Agriculture and Fisheries has awarded the Fream Memorial Prize for 1918 to Mr. LEONARD C. ROBINSON, a student of the Harper Adams Agricultural College, Newport, Salop, who took the highest marks at this year's examination for the National Diploma in Agriculture.

PROPOSED SCOTTISH RESEARCH STATION FOR PLANT BREEDING.—The Highland and Agricultural Society of Scotland has agreed to give a grant of £2,000 towards the proposed Scottish Research Station for Plant Breeding, on condition that the Board of Agriculture for Scotland provides at least an equal sum to that raised from other sources, and that representatives from agricultural bodies in Scotland should be represented on the governing body. It is proposed to confer with the Scottish Seed Trade Association, which is interested in the matter. The aim of the promoters is to raise a sum of between £20,000 and £30,000.

THE PUBLIC SERVICES OF A GARDENER'S SON.—The Prime Minister, in a letter of appreciation of Sir JOHN BETHELL'S services to the Secretary of the Committee appointed to present him with an illuminated address, says: "To represent the largest constituency in this country during the entire life of the present Parliament is a work which few people outside Parliamentary life can quite properly appreciate. But the member for Romford is a man who has devoted his great business capacity to the service of his constituency and of his country; his untiring and patriotic support of the war has been a wonderful example to all, and for this alone his constituents may well feel proud of him." Sir JOHN H. BETHELL, Bart., is one of the sons of the late Mr. GEO. BETHELL, who was for many years gardener to the late Sir GREVILLE SMYTH, of Ashton Court, Bristol.

RURAL WORK FOR DISCHARGED SERVICE MEN. Sir CHARLES WAKEFIELD, Bart., on the occasion of his installation as Master of the Worshipful Company of Gardeners, outlined a scheme for settling discharged soldiers and sailors on the land. He stated that two of the most difficult problems arising out of the war were demobilisation and food production, and these were capable of being dealt with in relation to each other. The State had already initiated a policy of settling discharged service men on the land, in the Small Holdings Colonies Act of 1916, but the action of the State would need to be supplemented by outside resources. In order to forward the movement he offered to present a sufficient number of acres to serve as the nucleus of such a colony. In addition to the cultivation of food stuffs, Sir CHARLES suggested that such a scheme might encourage such aids to the support of the smallholder as bee-keeping and rabbit breeding. The initial expenditure in bee-keeping was small, and with ordinary good fortune more than the whole outlay could be recouped in the first season. It was obvious that the more widespread practice of bee-keeping would have been invaluable in meeting the sugar shortage. Food for the rabbit would be obtainable at first hand from the garden refuse and the adjoining country lanes. The breeding and rearing of this prolific animal were now recognised as being the quickest means of producing good animal food. He added that it might be necessary, and the possibility must be borne in mind, to provide housing accommodation for the small-holders and their families. He saw no reason why, with the certainty of Government support to the small-holding movement in the organisation of markets, and in the intelligent distribution of market commodities, the colony should not speedily become self-supporting.

WAR ITEM. The Military Cross has been conferred on 2nd Lieut. J. E. CORRY, sixth son of Mr. WM. LONGMAN CORRY, of the firm of CORRY AND CO., agricultural and horticultural sundries merchants, Bedford Chambers, Covent Garden, and Shad Thames, London. 2nd Lieut. CORRY obtained his commission in June, 1917, in the 1st Batt. the Queen's Royal West Surrey, after passing through the Household Brigade Officers' Cadet Batt. School at Bushey, Hertfordshire.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

A BIBLIOGRAPHICAL CURIOSITY.—I have recently come into possession of a curious old volume on flowers, and am wondering whether any readers of the *Gardeners' Chronicle* can throw any light upon it. In size it is approximately 14 inches by 9½, and consists of 87

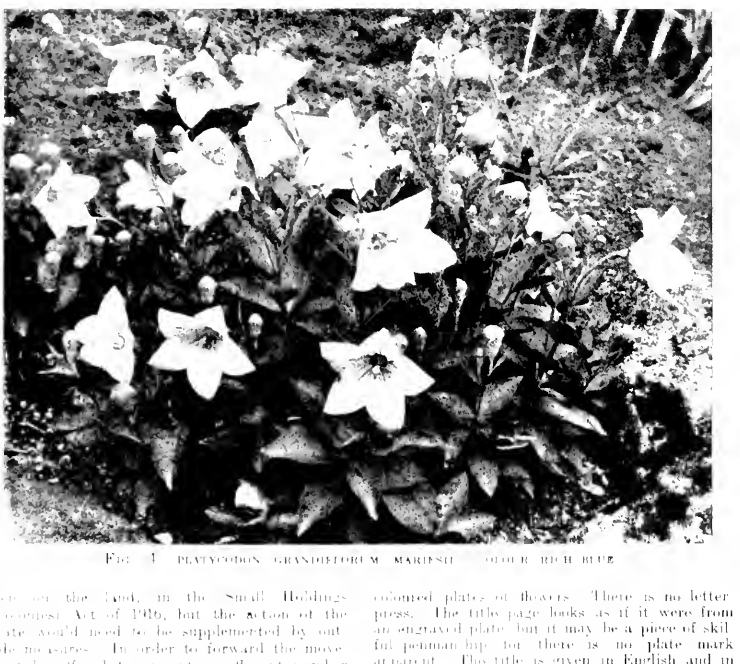


FIG. 4.—PLATYCODON GRANDIFLORUM MARIESII.—COLOUR RICH BLUE.

coloured plates of flowers. There is no letterpress. The title page looks as if it were from an engraved plate, but it may be a piece of skilful penman-ship, for there is no plate mark apparent. The title is given in English and in French as follows: *The English Flower Garden* ... *Le Jardin de Fleurs Anglois*. There is no date, or place of printing. On looking it through, the plates seemed to me to be familiar, and I was not long before putting my hand on the original. The plates are reprints of those in that very rare book, *The Compleat Florist*, 1730. The book probably contained the whole hundred illustrations, as every one of the 87 have been printed from, and can be identified with, those in *The Compleat Florist*. It is curious that in reprinting them for *The English Flower Garden* the original plates have had the engraved numbers and cultural matter blocked out, and there is the impress of the screen used for this purpose upon each plate. Whoever did it has written in all the name of each flower represented. A curious deceptive effect is given to these later productions by their being printed in brown ink, the originals being in black. Then to render the deception still more complete, most of the subjects illustrated in *The English Flower Garden*

are coloured quite differently from those in *The Compleat Florist*. The effect is very curious, but the whole fraud—for it is nothing more or less—can easily be ascertained by close examination and comparison with the original engravings. The order in which the plates appear has, of course, been entirely changed, hence another little barrier to create difficulty in recognition has been adopted. Perhaps Mr. W. Roberts, Mr. B. B. Brotherston, or some other bibliophile could throw light on this curiosity. *C. Harman Payne.*

TO PREVENT BEES SWARMING.—As one interested in bees, may I be allowed to refer to the notes by *Chloris* on preventing swarming, on p. 245? There is one most important detail omitted, and which must be carried out, otherwise the object in view will be defeated. Four or five days after supering, each of the frames of brood chambers that were raised above the queen excluder must be examined again for queen cells, and any found must be removed, or swarming will not be prevented. Only this week I examined two hives similarly treated, and on one frame found three queen cells, which, had they been allowed to remain, would have resulted in the old queen leaving the brood chamber, and other troubles. *E. Beckett, Fota Gardens, Queenstown.*

THE CAUSE OF THE APPLE FAILURE. *Market Grower*, on p. 243 suggests that the failure of the Apple crop is due to the brightness of the weather at blossoming time, causing the flowers to dry before they had all been pollinated by bees. Is not the failure due to the fact that the trees last year carried such enormous crops that they were weakened in consequence, and could not carry out nature's requirements properly in fertilising the blossoms? I noticed when the flowers expanded that they were weak and lacked the individual strength of those of the previous year. I feared the fruit would not set well, and the result confirms my earlier doubts. *E. M.*

LATE FROSTS IN SOMERSET.—During the past week we have experienced severe frost in this district. On the moors at Sharpham and Ashcott, between here and Bridgwater, maincrop Potatos to the extent of several acres have been badly damaged. On the 25th ult., Kidney Beans and Marrows were cut to the ground level and quite destroyed. Some plantations have almost entirely escaped damage, whilst others close by are practically ruined. Local growers are of the opinion that the King Edward Potato has withstood the frost better than Arran Chief. *Edward Carter, Abbey Gardens, Glastonbury.*

BEE STINGS.—Referring to your reply to *C. P.* on p. 266, I find that the simplest remedy and the most certain is a poultice of genuine honey. I am often stung, but suppose I am inoculated with the poison, as I never feel any pain beyond the prick. The above remedy will also give quick relief in the case of stings by gnats, mosquitos, and other insects. *Arthur Lewis, Sparrowswick, St. Albans.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

JUNE 18. — *Present*: Mr. E. A. Bowles (in the chair), Dr. A. B. Rendle, Messrs. J. W. Odell, W. C. Worsdell, W. Hales, E. J. Allard, and F. J. Chittenden.

The late Mr. R. Hooper Pearson.—The Chairman referred to the loss the Committee had sustained by the death of Mr. R. Hooper Pearson, whose wide knowledge and sound judgment had been of great value to the Committee. The Committee unanimously desired that their sincere condolences be sent to Mrs. Pearson and her daughter.

The Committee's Jubilee.—Mr. Bowles referred to the fact that fifty years had now elapsed since the formation of the Scientific Committee, the first meeting of which was held on April 20, 1868, and he brought a message of congratulation and thanks from the Council for the work done in the past, and their good wishes for the future. Of the original Committee only one member, Mr. J. G. Baker, F.R.S., remains alive.

Habenaria.—Dr. Rendle reported upon a plant of Habenaria chlorantha collected by Mr. Percy Bunyard at Woldingham as follows:—In the flowers sent the peculiarity is the multiplication of the fertile anthers. A number of pairs of pollen sacs are produced on the column successively inside the normal one. These all contain pollen, even the smallest ones having a few grains.

Silver Leaf in Apple.—Sir Harry Veitch sent branches of Apple Newton Wonder from East Burnham Park, the entire foliage of which showed the silvery appearance characteristic of the attack of Stereum purpureum.

Double Potentilla reptans.—Mrs. Colville sent a plant of Potentilla reptans with double flowers which she had found growing wild in Oxfordshire. Mr. Allard mentioned the occurrence of another double plant of the same species at Southwold.

Pollination of Mistletoe.—Mr. Bowles referred to the absence of knowledge concerning the flies which pollinate Mistleto, and said that he had captured several species at the flowers which had not all yet been named. Diptera appear to be the chief agents.

Change of Colour at Base of Tulip.—A letter drawing attention to a change in the colour of the base of the Tulip Eclipse was read from Messrs. Barr. When shown last year, the base of those grown under glass was much less defined than in those grown in the open, and the Tulips were considered distinct. This year, when bulbs from the two sources were grown side by side, the bases in both were alike, thus showing that the basal colour is not invariable, or independent of external conditions.

Lily from Saloniki.—Mr. Bowles showed flowers of a very dark form of Lilium Martagon from Saloniki, not of so dark a colour, however, as dalmaticum.

Mint.—Shoots of a Mint were sent from the Devon Medical Herb Industry. Plants were grown last year as Mentha viridis, some were transplanted, and this year shoots with very hairy foliage had appeared. Mr. Fraser recognised the shoots as those of Mentha sylvestris.

JULY 2.—At the meeting held at the Drill Hall, Buckingham Gate, on Tuesday last, there was a fair display of hardy flowers, Roses and Orchids, but there would have been a comparatively small show without the fine groups of Sweet Peas contributed by members of the National Sweet Pea Society. The Floral, Orchid, and Fruit and Vegetable Committees held short sittings, as very few novelties were presented for consideration. The Floral Committee recommended three Awards of Merit to novelties and awarded eleven medals for groups of flowers and plants. The attendance was satisfactory up to the luncheon hour, but small afterwards.

At the 3 o'clock meeting of the Fellows, Dr. E. J. Russell, of Rothamsted, gave a lecture on "Soil Making."

Floral Committee.

Present: Messrs. Henry B. May (in the chair), John Green, G. Reuthe, John Heal, J. T. Bennett-Poë, A. Turner, J. W. Moorman, C. Dixon, Chas. E. Pearson, W. P. Thomson, Jas. Hudson, E. H. Jenkins, Geo. Paul, E. A. Bowles, W. J. Bean, Sydney Morris, R. C. Notcutt, H. Cowley, W. B. Cranfield, J. F. McLeod, W. H. Morter, J. W. Barr, R. W. Wallace, A. G. Luckman and C. Elliott.

AWARDS OF MERIT.

Campanula Phyllis Elliott.—A charming little hybrid obtained by crossing C. excisa with C. arvatica (the presumed parentage of C. kewensis). The tiny basal leaves are ovate and toothed, while the stem leaves are linear. The flowers are borne stiffly erect, and there may be from one to four flowers on the wiry stems, but only a single bloom of each inflorescence is expanded at one time. The flowers are over three-quarters of an inch long, deeply lobed, and of a soft gentian blue colour. Shown by Mr. CLARENCE ELLIOTT, Stevenage.

Campanula kolenatiana.—This new Campanula promises to be a useful garden plant, as it has a good habit and is wonderfully free-flowering. A foot or less in height, the wiry, lispid stems bend slightly beneath the weight of the four or five large blooms produced at the top. The flowers are pendent, with recurving lobes, and the colour is deep porcelain blue, with darker shading on the lobes. The calyx and leaves are more or less hairy. The species is from the Caucasus. Shown by Messrs. R. TUCKER AND SONS, Oxford.

Escallonia edinensis.—This graceful hybrid was raised in the Edinburgh Botanic Gardens, hence its name. The small flowers are rose-pink and borne freely on the new growths, which are produced closely together all along the arching branches. The small, shining green leaves form a pleasing setting for the abundant blossoms. E. edinensis, like E. langleyensis, is derived from the Valdivian E. Philippiana crossed with the Chilian E. punctata, and the two plants are very similar in every respect save the shade of colouring, which appears to be deepest in E. langleyensis. Shown by Messrs. PAUL AND SONS, Cheshunt.

OTHER INTERESTING PLANTS.

Messrs. R. WALLACE AND CO.'s group of Eremuri attracted a great deal of attention, and the different shades of gold presented by the several forms of Eremurus Bungei were most pleasing; E. Olgae and E. Sir Michael were also included, as well as Iris aurea in fine form. Flowers of Lonicera tragophylla were to be seen in Mr. G. REUTHE'S group, where the Bee Orchis and the handsome Orchis foliosa were close companions. Messrs. WM. PAUL AND SON made a big show of their new Waltham Scarlet Rose; the new rose-red Hadley was conspicuous in Messrs. B. R. CANT AND SONS' exhibit of Roses; while Messrs. ALEX. DICKSON AND SONS showed their handsome K. of K. Rose, a brilliant velvety-crimson variety.

GROUPS.

Medals were awarded to groups as follows:—*Silver-gilt Banksian.*—Messrs. B. R. CANT AND SONS, for Roses. *Silver Flora.*—Messrs. R. WALLACE AND CO., for Eremuri; Messrs. ALEX. DICKSON AND SONS, for Roses; Mr. L. R. RUSSELL, for fine-foliaged trees and shrubs. *Silver Banksian.*—Messrs. R. TUCKER AND SONS, for Alpines; Messrs. H. B. MAY AND SONS, for Ferns and Hydrangeas; Messrs. WM. PAUL AND SON, for Roses; Mr. G. W. MILLER, for hardy flowers. *Bronze Flora.*—Mr. G. REUTHE, for hardy plants. *Bronze Banksian.*—Mr. CHAS. TURNER, for varieties of Philadelphus; Messrs. J. CHEAL AND SONS, for Star Dahlias in ten varieties.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Sir Harry J. Veitch, Messrs. Jas. O'Brien (hon. secretary), Arthur Dye, J. Wilson Potter, W. H. White, R. A. Rolfe, William Bolton, J. Charlesworth, T. Armstrong, F. Sander, R. G. Thwaites, Frederick J. Hanbury, and C. H. Curtis.

AWARDS.

PRELIMINARY COMMENDATIONS.

Odontoglossum Jasper, Ashtead Park variety (crispum × amabile), from PANTIA RALLI, Esq., Ashtead Park, Surrey (Orchid grower, Mr. W. H. White).—A distinct form, approximating more closely to O. crispum, which is the leading factor in its ancestry, than any other hybrid of this cross yet shown. The large and finely formed flower is pure white with clusters of dark purple blotches in the middle of each segment; the lip has a yellow crest.

Odontoglossum Promerens Princess Mary (eximium × crispum), from Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells.—A model flower with pure white ground, the sepals having two broad, irregular bands of reddish-mauve colour and the petals a large blotch of reddish mauve in the centre; the well-developed lip has dark markings around the yellow crest.

GROUPS.

Messrs. ARMSTRONG AND BROWN were awarded a Silver Flora Medal for an excellent group of hybrid Orchids, with a few interesting species which included Anguloa Cliftonii and the rare Cypripedium Druryi. The best novelties were Odontoglossum Cynthia (eximium × Mars), a fine white, handsomely blotched variety; two

examples of a very delicately tinted type of O. eximillus, with strong spikes of light rosy-lilac flowers; and Laeliocattleya Aeis Queen Mary (Mendelii × tenebrosa), with pretty, pure white flowers having pink labellums with chrome-yellow disc.

Messrs. CHARLESWORTH AND Co. were awarded a Silver Flora Medal for a fine group in which forms of Miltonia Charlesworthii were the principal feature. New hybrids shown were Odontioda Lyra (Odm. Jasper × Oda. Royal Gem) and Odontioda Lorna (Oda. Lambeauiana × Odm. Olympus), both of good quality. The group included a plant of the rare Cirrhopetalum pulchrum var Cliftonii, with a fine umbel of cream-white flowers spotted with dark rose.

Fruit and Vegetable Committee

Present: Messrs. Joseph Cheal (in the chair), E. A. Bunyard, W. H. Divers, Edwin Beckett, W. Bates, P. D. Tucker, Owen Thomas, A. Bullock, J. C. Allgrove, and Geo. Relf.

AWARD OF MERIT.

Melon Acquisition.—This Melon is scarlet fleshed, of good flavour, and has a handsome and closely netted skin. Shown by Mrs. B. B. Fox (gr. Mr. E. A. Hall), Brislington House, Bristol.

NATIONAL SWEET PEA.

JULY 2.—The National Sweet Pea Society held an exhibition on this date in conjunction with the Royal Horticultural Society's meeting, and provided a far finer display than in 1917.

The Floral Committee examined seven novelties and made descriptive records of new varieties for the purpose of keeping the classified lists as complete as possible. The General Committee met at 12.30, and many well-known amateur and trade growers were present.

No classes were provided and no prizes offered, but members had been invited to send blooms. All things considered, the response was excellent. Mr. W. H. HOLLOWAY, Post Hill, Shrewsbury, had by far the finest display which consisted of two dozen bunches of well-grown flowers. Lady Miller, President, Agroona Beryl (a lovely pink), Golden Glow, Warrior, Liberty, Prince George, Audrey Crewe, and Lord Evelyn were a few of the varieties shown. The group which thoroughly merited the Large Gold Medal awarded. Messrs. DOBBIE AND Co. set up a few of their novelties, notably Mrs. J. Jones (deep mauve), and an unnamed seedling akin to Elegance (Gold Medal: Elegance and Mr. J. W. Bishop were the only two varieties shown by Messrs. ALLAN DICKSON AND SONS, but they were represented by numerous large stands and vases of first-rate blooms. (Gold Medal.)

Fiery Cross, Royalty, a cream-ground form of Rosabelle, and Gladys, a new silvery-blue variety, were contributed by Messrs. E. W. KING AND Co. (Silver-gilt Medal). HOWARD S. BUTTON, Esq. (Berries, Duck's Hill, Northwood (gr. Mr. George Herbert), sent a score of bunches of the best varieties (Silver-gilt Medal). Mr. ROBERT BOLTON sent a few flowers of new varieties, the most striking of which was a unnamed cream-ground variety with heavy rose-pink flushings on the back of the standard.

Other exhibitors were Mr. R. SANDFORD, Barton Mills, Suffolk (Silver Medal); Mr. S. F. CURTIS, Wingate Lane Road, Lancaster, who had an interesting seedling of the Olive Ruffel type named Devotion; Mr. G. J. E. PRYOR, Preston Hitchin (Silver Medal); Mrs. FARNHAM (Silver Medal); Mrs. W. H. HOLLOWAY, Shrewsbury (Silver Medal for a decorative vase); Mrs. REID, Bedford (Silver Medal for an épergne); Mr. WORTHINGTON (Bronze Medal); Mr. BARKER (Bronze Medal); Mr. LOUGHTON, Ashford, Middlesex; Mr. J. STEVENSON, Poole Road, Wimborne, who showed his fine variety Liberty and a new rosy mauve variety named Hallo; Dr. HINTON, Heytesbury; and Mr. DAVIS, Ilford.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

JUNE 10.—The monthly meeting of this Society was held in the R.H.S. Hall on Monday, the 10th ult., Mr. C. H. Curtis in the chair. Two new members were elected. The Army forms of the late Sergt. F. Harris and Pte. M. Whiting were received, and the sum of £21 0s. 8d. was passed for payment to their respective nominees. One lapsed member was allowed to withdraw £10 10s. from the funds. The sick pay for the month on the Ordinary side amounted to £74 8s. 3d., State Section £18 10s., and Maternity Benefits £7 10s. The treasurer stated that the trustees had invested a further sum of £500 in War Bonds, and had a balance in hand of £318 2s. 6d.

CROPS AND STOCK ON THE HOME FARM

FALLOWS.

THE recent weather is all in favour of cleaning vacant land where Couch is prevalent. Continuous ploughing, dragging, rolling and harrowing of the land, and collecting the dried Couch with chain harrows, afterwards burning it in small heaps on the land, should leave but little weed in the soil. If the Couch is not removed now there may not be a chance to do so later. Where Swedes and Turnips are to occupy the land, these crops to be followed by corn, the ground should be thoroughly cleaned.

MANGOLD.

OWING to the unusual ravages of the Turnip fly this crop is patchy in some areas. Where the early plants have been thinned and kept free from weeds the crop is growing satisfactorily. Any late pots should be thinned at once. The drills are usually made 18 inches apart, and the plants in the rows should be thinned to about 15 inches asunder. There is a difference of opinion amongst growers as to which method—a thin or medium plant—produces the heaviest yield of roots. Some contend that a thin plant enables the roots to grow larger, while others are of the opinion that a medium sized root, obtained by giving less space, produces the greater bulk of roots. I am of the latter opinion, and think also that the roots are of superior quality, containing more saccharine and nutritious matter than large specimens. After thinning the plants hoe the ground and the soil to the depth of 1 inch at the rate of 1 cwt. per acre and repeat the dressing a month later. Keep the surface well stirred in dry weather and hoes to admit air to the soil and check the growth of weeds.

RENOVATING PASTURES.

The existing spell of dry weather has reduced to a minimum the grass in ridged pastures, which in fact has also reduced the quantity of milk. Where possible I put me thin lots been fed hard should be rested. After spreading the cow dung, and clearing off such weeds as ragwort and thistles, sow 1 cwt. per acre of sulphate of ammonia [illegible].

SUMMER FALLOW AND WHEAT.

As a preparation for Wheat, what is known as a summer fallow is one of the best of methods for ensuring success. This probably is one of the oldest practices in existence, and still one of the most certain of success when properly carried out. Summer fallowing means allowing the ground to lie idle, or free from a crop for several months, in the meantime ploughing it several times, thoroughly disintegrating every particle and exposing the surface to the influences of the weather. The absence of a crop leaves the soil with a full quantity of nitrogen stored ready for the next season's growth of Wheat. The exposure of the soil sets free the humus it contains. Farmyard manure added at the rate of 20 tons per acre previous to the last ploughing at the end of September will provide the soil with all the nutriment necessary to produce a full crop of high class Wheat the following season provided of course the weather is propitious.

Summer fallowing possesses the advantage of cleansing soil from weeds if the various details of ploughing, harrowing, and the burning of Couch are carried out judiciously.

For example take a field of Swedes eaten off in March or April by sheep, foul with Couch, Docks, Thistles, Camomile, or Tussilago Farfara (Colt's Foot). The constant ploughing from April onwards, always during dry weather, will thoroughly eliminate these weeds, and a clean plot can be assured by the time for sowing the Wheat. *C. Molyneux.*

Obituary.

ABRAM VALLANCE.—The death occurred on Thursday, June 20, at his residence, Bexwell Road, Downham Market, of Mr. Abram Vallance, formerly of the firm of Messrs. Bird and Vallance, nurserymen and seedsmen, Downham Market. Mr. Vallance had been in failing health for some time past.

DAN MELLUISH.—Mr. Dan Mellish, one of the oldest horticulturists in Bath, died at Bath on June 20, on his 87th birthday. He was born at Batheaston in 1832, the son of Mr. James Mellish, and was apprenticed to Mr. Ambrose Minty, of Bailbrook Gardens. Later he became gardener to Mr. James Chaffin, and laid out the grounds at Charlcombe Grange. He was a successful exhibitor, and won many prizes. When his old chief, Mr. Minty, died, in 1885, Mr Mellish succeeded him at Bailbrook.

MATTHEW CRAWFORD.—Matthew Crawford, known as the "Gladiolus King" of Ohio, and prominent for many years as a Strawberry specialist, died recently at his home in Belle Center, U.S.A., after a three days' illness following an attack of pneumonia. He was 79 years of age. Deceased was born in County Antrim, Ireland, and following the death of his father, he went to America when ten years of age, accompanied by his mother and younger brother. In 1856 Matthew Crawford engaged in market gardening, and since that time until his death he made horticulture his life work. In 1876 he began making a specialty of Strawberry plants, and a few years later became well known as a successful grower of Gladiolus bulbs. He had grown as many as two million bulbs in one year, which he supplied to the markets, and also made large shipments of flowers during the season. Among his best known works is *The Book of Gladiolus*, written by him in 1911, in collaboration with Dr. Van Fleet.

TRADE NOTES.

THE FRUIT ORDERS.

A STRONG protest is being made by traders in Scotland against the recent Fruit Orders of the Food Controller. The president and secretary of the Edinburgh and Leith Fruit and Flower Trade Association have protested against the Order commandeering soft fruit. The president and secretary of the Edinburgh Wholesale Fruit Merchants' Association also take strong objections to the Order, especially as regards Strawberries. They point out that the Scottish crop being later than the English one, the growers in Scotland have been placed in a worse position than those in England, as the latter had sold much of their crop before the Order was issued.

FRENCH BULBS.

IT does not appear to be generally known among traders that the British Customs authorities now hold a general licence for the admission of bulbs from France. The bulbs must be of French origin, otherwise importation will not be permitted. On paper it is a fairly easy matter to place orders for French bulbs, but it is quite another matter for the French grower to convey his goods to the seaport, while transport from France to England is a big obstacle in the way of their speedy transmission to the British buyer.

CO-OPERATIVE FRUIT MARKETING.

THE sales for the past year of the Pershore Co-operative Fruit Market amounted to £81,857, being an increase of £35,905 over the previous year, while the profit realised was £3,042. The committee recommended a bonus of £3 15s. per cent. to shareholding growers in proportion to the value of their produce marketed.

ENQUIRY.

CHALK AS FUEL.—It has been stated that chalk can be made use of as fuel, and it would be interesting to have the experience of those who have tried this material for the purpose. *T.*

MARKETS.

COVENT GARDEN, July

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate not only from day to day, but occasionally several times in one day.—EDS

Smilax per bun. of 6 trails ...	2 6– 3 0	

REMARKS.—There is still a shortage of white flowers, and prices remain high for Achillea, double white Stock, and white Pinks. Many good varieties of Delphiniums are on sale. There is a good supply of Gypsophila elegans, which is arriving in good condition. Sweet Peas are also good and sufficient for the demand, but prices remain firm. Spanish Irises are practically finished for this season. Roses continue fairly plentiful. The best sorts offered are Mme. A. Chatenay, Molly Sharman Crawford, Fran Karl Druschki, Melody, Ophelia, Liberty, and Sunburst. The latest arrivals are Alstromeria and scarlet Gladiolus Brenchleyensis. Foliage now consists of Asparagus plumosus, Asparagus Sprengeri, and Adiantum Fern. Smilax is not being grown in very large quantities, and the consignments are very irregular.

Watercress, per doz	0 10– 1 0	

REMARKS.—Trade in fruit is limited in consequence of the outdoor soft fruits being required for preserving. Glasshouse fruits are therefore in better demand, the principal items of which consist of Grapes (Black Hamburgh and Muscat of Alexandria), Peaches, Nectarines, Figs, Melons, and Cherries. Some fine samples of Sicilian Oranges are on offer. Tomatos and Cucumbers are more reasonable in price. Peas and Broad Beans are plentiful. Supplies of Cauliflowers, Cabbages, and Dwarf Beans are limited. Mushrooms are, as usual at this time of year, limited in supply. *E. H. R., Covent Garden Market, July 3, 1918.*

GARDENING APPOINTMENTS.

MR. S. WREN, late Gardener to D. LIONEL THOMSON, Esq., Temple House, Waltham Cross, Hertfordshire, as Gardener to Sir GUY SEBRIGHT, Cheverells, Dunstable. (Thanks for 2s. 6d. for the R.G.O.F. box.—EDS.)

MR. F. A. BUSH, late Foreman at Bowood Park, Wiltshire, as Gardener to Sir IAN H. AMORY, Knights hayes Court, Tiverton, Devonshire, during the absence of Mr. Johnston on Army service.

ANSWERS TO CORRESPONDENTS.

"FROG SPIT".—*Hillyfield.* The frothy substance on your plants is caused by the insect variously named Frog Hopper, Frog Spit, and Cuckoo Spit (Aphrophora spumaria). The plants can be cleared of the insects by brushing off during sunshine the protective "froth," without which they cannot live. Another method is to syringe the plants with lukewarm nicotine or Quassia extract; if the former is used, it should be washed off the plants with clear water about an hour after application.

HYDROCYANIC ACID GAS: *A. B. H.* It will be quite safe to fumigate the house where there are ripe fruits of Tomatos and Cucumbers, but it would be well to wash the fruits before use if they are required very soon after the fumigation.

MUSCAT OF ALEXANDRIA GRAPES: *L. G.* The berries are "scalded," the cause being excessive warmth during the stoning stage. They will not scald while the shaded temperature does not exceed 80°, but if it rises to 90° scalding is almost certain to take place. The stoning period lasts about four weeks, during which time there is no expansion of the berries, and the most critical time is during the latter half of this period. Let the vinery be amply ventilated, and sprinkle water on the floors and walls during the hottest part of the day to promote atmospheric moisture. Sometimes it may be necessary to have recourse to temporary shading during midday, but this should be avoided if possible. As soon as the second swelling commences all danger will be past, and a maximum temperature of 90°, if combined with general good treatment, will then do the vines or bunches no harm.

NAME OF PLANT: *E. Taylor.* Scilla indica, Baker, at one time named Ledebouria hyacinthina, Roth. See *Botanical Magazine*, t. 3,226. After flowering the soil should be allowed to dry out gradually, and the plant fully exposed to sunshine for some weeks. Most or all of the foliage will die down, after which you should separate the bulbs and repot them in moist soil. After one good watering spray or lightly syringe the bulbs twice a day till fresh growth commences, when you can begin watering again, increasing the supply of moisture as the leaves get freely into growth.

POTATO LEAVES DAMAGED: *B. & Sons.* The marks on the Potato leaf are apparently not due to any attacks from insects or fungi; they are probably the result of unfavourable weather conditions.

POT PLANTS SUITABLE FOR USE INDOORS: *J. B.* A variety of Primulas are suitable for room decoration. The stellata varieties of Primula sinensis are especially valuable, as they have a wide range of colour; Primula obconica, P. kewensis, P. malacoides and P. verticillata are all suitable, and can easily be raised from seed. Begonias of the Gloire de Lorraine type are useful; the newer Mrs. Paterson is especially fine, as its coloured foliage lights up beautifully under artificial light. Among zonal and show Pelargoniums there is a wide range of colours, and in light, airy positions the flowers last well. Hydrangeas, of which there are many choice varieties, are very valuable for their lasting properties; Saintpaulia ionantha is always a favourite plant. Cyclamen are invaluable in their great variety of colours, Achimenes, Gesnera or Naegelia, and Clerodendron fallax are also serviceable in their season. The smaller Acacias, such as A. Drummondii, A. platyptera and A. hastulata; Boronias and various Ericas are deserving of consideration, but their growth is considered too slow and difficult by the present-day cultivator. The following is a list of plants that can be grown annually from seed, and their flowering covers a wide season. If grown cool and sturdy the plants are all suitable for house or room decoration:—Acroclinium, Antirrhinum (intermediate varieties), Browallia elata (blue and white), Campanula pyramidalis (blue and white), Celosia plumosa, Cinerarias (especially the intermediate star varieties), Clarkia elegans (in several varieties), Godetias (especially the tall double forms), Larkspurs (Stock-flowered varieties), Mignonette, Nemesia strumosa Suttonii Rhodanthe, Salvia splendens (using one of the best dwarf forms), Statice Suworowii, Schizanthus Wisetonensis, Stocks of the intermediate type, such as East Lothian, also the taller Beauty of Nice type; Trachelium coeruleum, and double Wallflowers. Hippeastrums are easily raised from seed and are very handsome for house decoration; Clivias are also very suitable, as are such bulbous plants as Freesias, Narcissus, Tulips, and several Liliums. *The Greenhouse: Its Flowers and Management*, by H. H. Thomas, price 1s. 6d., and *The Book of The Greenhouse*, by J. C. Tallack, price 3s., would be suitable works for your purpose. They may be obtained from our Publishing Department: the prices include postage.

RHODODENDRON EATEN: *G. F.* The insect causing the damage is the Rhododendron bug, Stephanitis rhododendri. It is prevalent in the Woking area, and has been found at Sevenoaks, but nowhere else. It can be controlled in nurseries by spraying with paraffin emulsion now, while the insect is in the nymphal and larval stages.

WEED IN POND: *W. H. W.* The weed you submit to us is Lemna minor, the lesser Duckweed. You should skim it off the surface, and introduce goldfish into the pond, as they will eat the weed. Ducks would, of course, do the same, but they might injure the rock plants.

FRUIT PRESERVING WITHOUT SUGAR.

MANY growers are concerned that their surplus fruit may be wasted this season owing to a shortage of sugar for jam-making. Yet there are many easy methods of preserving fruit without sugar. The reason why fruit "goes bad" is that it falls a prey to various living micro-organisms, especially bacteria, yeasts, moulds and their spores, all of which may conveniently be included in the popular term "germs." To preserve any food, it must be sterilised—i.e., freed from all germs, and then be kept so that no others can attack it.

When fruit is kept in cold storage, micro-organisms are prevented by the low temperature from developing, and therefore the fruit keeps good for a long time. The germs, however, are not killed, and as soon as the temperature rises they regain their normal activity and cause the produce to decay. Refrigeration is, therefore, only a temporary measure of preservation. Drying is also only temporary in that, if the produce be allowed to become moist again, decomposition will soon set in. While dry, however, fruit and other perishable foods are not suitable media for the growth of germs owing to the tendency for water to be extracted from the living organism by the dried tissue of the fruit. The fungus, therefore, loses water in this way, and if not actually killed, will, at any rate, be unable to thrive so long as the dried produce is well stored in a dry place. When the necessity for these precautions is realised, drying is a good and very simple method of preserving fruit or vegetables, and can be practised by those who have no special apparatus. Suitable trays can easily be made by stretching strong cheese-cloth, canvas, wire gauze, or other porous material across a wooden frame of suitable size to fit the oven. The fruits or vegetables to be dried should be spread out evenly on the trays, which may be placed in the sun by day and in a cool oven with the door open by night. Drying is best done intermittently, so that moisture from inside the fruits or vegetables has time to diffuse out before the skin becomes too dry. It must be continued until moisture cannot be squeezed from a cut surface of the produce in process of drying, which must not be carried to such a degree as to cause the fruit to become brittle. On no account must the produce be charred or scorched, as it may be if the temperature is allowed to rise above 160° F., for then it would change chemically and be incapable of regaining its usual form when soaked in water. Perhaps drying is most successful in the case of Apple rings (⅛ to ¼ inch thick), Plums or Damsons to form Prunes, Grapes for Raisins, and vegetables such as Peas and Beans, in addition to herbs so universally prepared in this way.

For some purposes sterilisation is often effected by disinfectants or antiseptics. Many such substances are more or less powerful poisons, and consequently unsuitable for using with foods. Some of the weaker antiseptics do nothing worse in this respect than upset the digestion to a greater or lesser extent, and are therefore not desirable, neither are they necessary. The least objectionable antiseptic from this point of view is sulphur dioxide, which, being a gas, may be driven off again by heating, and is sometimes very useful in helping to sterilise ordinary jam jars.

By far the best method of sterilising food of all sorts is by heat. The organisms which attack fruit are all killed before the temperature of boiling water (212° F.) is reached. They may be weakened and finally destroyed at a temperature so low as 150° F. to 170° F., provided it is maintained for a sufficiently long time.

This method of sterilising is made use of in canning and bottling. The great difficulty in preserving in ordinary bottles is to close them so that, after all spores and germs have been destroyed inside, no others can gain an entrance. This can only be done by the most meticulous attention to details. It must be remembered that, however clean the hands, cloths, table, etc., may appear they are never really sterile. Even the cleanest looking bottle or its lid may be covered with germs, which will grow and multiply rapidly if supplied with any suitable medium as food. In fact, after sterilising a bottle of fruit, it is essential that no part of the inside of the bottle be touched by any unsterilised body, nor must it be covered by anything that is not sterile. If allowed to remain open for many minutes the contents are liable to be infected from the air. The best way to secure perfect sterility is to sterilise the container after the food has been put in and hermetically sealed. This is the method by which modern canning in tin cans is carried out, and when once perfect sterility has been secured in an airtight container, the contents will theoretically remain good for ever. The process of canning is simple. A can of suitable size is packed with fruit as tightly as possible, filled with boiling water, the lid soldered on, and the can, together with the contents, sterilised in steam or boiling water, the time necessary for this process being 10 to 30 minutes, according to the softness of the fruit. The can may be immediately afterwards plunged into cold water to prevent overcooking. If boiling water is not available for filling, cold water may be used, but this makes the subsequent operations somewhat longer.

The superiority of canning over bottling is due chiefly to two facts. In the first place, as there is no risk of cracking, tin cans may be dealt with very rapidly by plunging them into boiling water and afterwards into cold; this makes it possible to deal with a glut of fruit, since three or four girls may deal with as many as 600 3-lb. cans a day. Secondly, cans may be sterilised after hermetically sealing, whereas bottles must be left open throughout this process, and consequently the contents lose flavour, and may subsequently become infected while being closed. However, many people have not yet surmounted an inherent and quite unjustifiable prejudice against tinned foods, and others will probably decide to manage with the bottles they already possess. If these bottles are the patent, so-called, vacuum ones, all should be well, but if ordinary jam-jars have to be used, detailed information as to the best methods of sealing should be obtained. For those with no suitable boiler, the oven method is probably best, and the following procedure is recommended for soft fruit: Take the number of clean vacuum jars required, and also a few extra receptacles, such as jugs. Fill all with clean fresh fruit and stand them on folded paper or cardboard in a moderately hot oven. In about half an hour the fruit will be found to have sunk down in its own juice. During this preliminary heating it is usual to cover the vacuum jars with their lids, which will thereby also be sterilised, but the rubber rings should not be heated for so long owing to their liability to perish. Take out the jars one at a time, fill up with fruit from one of the extra receptacles, dip the rubber ring in boiling water, place in position, and adjust the lid. If the screw type of bottle is being used, the cover must only be screwed loosely so that there is still an outlet for any expanded gases on reheating. Each jar should be put back into the oven for about fifteen minutes to re-sterilise, and on removal should be at once screwed down tightly so that no air can possibly enter. If done successfully, the contents will keep good for so long as the rubber ring lasts, which will probably be three or four years, the ring being the only perishable part of the container. Fruit preserved in its own juice by this process, often called pulping, is much better for tarts, etc., than that to which water has been added, and a far larger quantity may be preserved in one receptacle. It may be easily heated, with a little water and sugar, as available, to make jam. There is no necessity to add the large amount of

sugar that was used in pre-war days; in fact, the flavour of jam is better if less than ¾ lb. of sugar to 1 lb. of fruit is used. When sugar was cheaper than fruit large quantities of the former were used, and this custom certainly had the advantage that in raising the density and osmotic pressure of the jam a medium was produced in which there was much less tendency for germs to develop than there is in a juice with the consistency of water. However, if jam is well sealed while hot, there is no difficulty about its keeping, however little sugar it may contain.

In conclusion, it should be pointed out that it is always well to keep "preserves" in a place readily accessible, so that they may be examined from time to time, for, owing to the fallibility of human actions and the persistence of germs, it is possible that an occasional jar may require to be re-sterilised or used at once. *H. Goodrich.*

and so have Strawberries. French Beans, so largely grown round Paris, are at a standstill, and it is doubtful whether they will flower and set their pods.

On the other hand, the dry weather has greatly favoured the pollination of flowers, and many plants which are poor seeders in a normal season are carrying an abundance of fruits, and especially is this the case with bearded Irises. The temperature has kept below the average, and in some low-lying districts it fell almost to freezing point at night about June 20. In the south-west of Paris, where fruit trees are largely grown, there will be hardly any Cherries, no Peaches, no Plums, and very few Pears and Apples. Were it not for the half-crop of Strawberries and a good crop of Red Currants there would have been no fruits at all in a district where hundreds of tons of fruit are produced almost every year. *S. Mottet.*

[Photograph by E. J. Wallis.

FIG. 5.—FLOWERING BRANCH OF DAVIDIA INVOLUCRATA.

FRENCH NOTES.

THE WEATHER AROUND PARIS.

THIS is a very poor season. After late frosts had destroyed the flowers of most fruit trees, and scarred the young growth of many Conifers, the beetle called "Lisette" destroyed half the flowers of Strawberries.

Dry weather set in about the middle of May, and since that time very few showers have fallen. Seedlings and annuals are suffering wherever watering has not been attended to. In fields, heavy soil is cracked, just as it is usually at harvest time. Spring Wheat has suffered, and is very short in the straw, and it is interesting to note that "rust" has developed upon some varieties, as much as, if not more than, in a wet season. Potatos look well, but need moisture. The early varieties have ceased growing, and the tubers are small and late. Potatos are not flowering here more than in normal years, but they may fruit more freely than usual; the fruits should be removed, as they are very exhaustive of the plant's energies. Disease is making its appearance upon some varieties of Potatos, notwithstanding the drought and total absence of night dews. Early Peas have all cropped together,

HARDY FLOWER BORDER.

MORINA LONGIFOLIA

OF the ten or twelve species of Morina only M. longifolia, M. persica (syn. Wallichiana), and M. Coulteriana, are common in gardens. Of these, by far the best known is the first-named, a capital and highly ornamental border flower, differing in its general aspect from almost any plant in bloom at the same time, and adding considerably to the attractiveness of the garden. It has long, ornamental, Thistle-like leaves, and tall spikes of flowers in whorls, from which it is known as the Whorl Flower. Apart from the whorled arrangement, which is pretty in itself, the individual flowers are of much charm. They have long tubes, and the blossoms open in succession; the flowers are white when they first expand, and pass off in various shades of rose. The plant grows from 2 to 3 feet high; it flowered here this year towards the end of May, and will last in bloom throughout June and into July. Of the other species in cultivation, M. persica is the one I know best, although I have seen M. Coulteriana. I do not think that those who possess M. longifolia need care much whether they possess the others or not. They seem to be slightly dwarfer. M. longifolia is not exacting respecting soil, but prefers a rather deep, moist medium. It thrives well in sun. It is not a plant which transplants well when large. Young plants are inexpensive, and seedlings can be raised still more cheaply, but fresh seeds should be sown. When the plant is not in bloom it has a resemblance to a Thistle, and may be destroyed as a weed by an inexperienced person. *S. Arnott, Maxwelltown, Dumfries.*

DAVIDIA INVOLUCRATA.

WE may now look upon Davidia as an established garden tree in this country, for, although when first introduced it was thought to be too tender for our climate, and was planted in the Himalayan section of the Temperate House at Kew, it has since proved as hardy as the Crimean Lime, which it resembles in some respects. All the same, the tree under glass at Kew is healthy and floriferous, the conditions provided for Himalayan Rhododendrons being evidently to its liking, as it has thriven splendidly since it was planted there in 1904. It was transplanted from the side to the centre of the house about ten years later. The photograph of the tree in flower reproduced in fig. 7 was taken by Mr. Wallis in May this year, when it was a most striking object, about 30 feet high.

The first account of Davidia published in the *Gardeners' Chronicle* was by the late Dr. Masters, in April, 1903, p. 236, and there have been several notices of the tree, descriptive and otherwise, since. The tree in the Temperate House at Kew was raised from a cutting taken from the first tree raised in Europe, which flowered with Messrs. Vilmorin, Paris, in 1908, and a flowering shoot was illustrated in *Gard. Chron.*, June 2, 1906, fig. 158. Mr. E. H. Wilson sent seeds of Davidia to Messrs. James Veitch and Sons in 1899, from which a large number of plants was raised, and afterwards distributed.

As one would expect in a tree with a fairly wide distribution in the mountains of China, Davidia shows some variation, but not more than many other trees do. The leaves in some forms are green on both sides, in others they are glaucous beneath, and the degree of hairiness on the young shoots and leaves is also variable. At Kew four forms or varieties may be discerned. M. Dode has made three species, namely, D. involucrata, D. laeta, and D. Vilmoriniana. There does not, however, appear to be any good reason for this, and as Dr. Hemsley, who has paid particular attention to the genus, has stated that they can only be classed as varieties of one species, for practical purposes his view ought to prevail. *W. W.*

THE MARKET FRUIT GARDEN.

AFTER a dry May a dripping June would have been very welcome. Instead of this the month had less than the normal rainfall and more than normal sunshine. It is true that rain fell on eleven days in my garden as compared with seven in the corresponding month of last year, but the total fall was only .95 inch against 3.5 inches. The heaviest fall was .28 inch recorded for the 19th; and the rest of the showers were so light that the effect quickly disappeared under the influence of bright sunshine and drying winds. Thus, at the close of the month, fruit trees still looked as though thirsting for rain, if only to cleanse them of the mess left by the plague of caterpillars of the Winter Moth group. Most of these pests have now disappeared, being fully fed, but their place has been taken on Apple trees by aphides and the larvae of the Lackey Moth, the webs of the latter being unusually numerous. Still, the trees show some slight signs of recovery from the former attack, though they have made remarkably little

growth in what should be the season of most rapid development.

BLACK CURRANTS.

Alternating sunshine and showers hasten the ripening of such crops as are near maturity. Black Currants coloured very rapidly this season, and were ready to gather by June 24, a week earlier than last year. Marketing has been a simple business, if less interesting than usual. All had to go to licensed jam-makers or to salesmen who guaranteed to sell only to them, and the Government price, 60s. per cwt. on rail, was the figure for the whole crop, early or late. Thus there was nothing to be gained by trying different markets. Simplicity is, however, the only advantage of the system so far as the grower is concerned. The price, which works out at 12s. 10d. per half-sieve, with no deductions for railway carriage or salesman's commission, looks tempting enough. When, however, the very low yield and the consequently increased expense of gathering are taken into account, it becomes evident that the price does not err on the side of liberality. Last year the bushes between trees in a 6 acre plantation yielded 946 half-sieves and the average return was 17s. 4d., after deducting all marketing expenses except carriage. This year the same plantation gave only 145 half-sieves, or less than one-third the previous crop, whilst the cost of picking was but little more than again. Nor was last year's yield a good one, for the crop from the same bushes in 1916 was 729 half-sieves. A neighbouring grower has had one-third of his crop of last year, so that this may fairly be said to represent the average of the district. To enable the pickers to earn something more than the current high day wages it was necessary to offer 1s. 6d. per half-sieve, as gathering is a slow business when the berries hang thinly. This is the highest price we have ever paid for Black Currants, it being half as much again as was given last year, which was an advance on anything previously offered. In the circumstances it cannot be said that the Government price represents the true value of the crop. Of the prices that have so far been fixed, that for Black Currants is the only one that affords us. Growers of Strawberries, Gooseberries, and Raspberries have far more cause for complaint, particularly where choice dessert fruit is produced by specialised and expensive methods of cultivation.

AMERICAN BLIGHT.

In a season which seems to suit all insect pests it is not surprising to find woolly aphis or American blight, on the increase. Winter spraying with a caustic wash is said to hold it in check, but I have not found this to be the case. There seems to be no effective remedy beyond treatment by hand during the summer months. I have generally brushed methylated spirit into the affected patches; this specific runs well into the crevices and does its work without injury to the tree. Now that spirit is practically unobtainable it becomes necessary to find a substitute. Paraffin immediately removes the "wool," and appears to destroy the aphides, but it evidently does not kill all the insects, as the patches appear again after a few weeks. Moreover, strong paraffin is not a desirable dressing from the point of view of the tree's welfare. An undiluted soft soap and paraffin emulsion is now being tried, something of a soapy nature generally being considered best for the purpose.

This pest is evidently strongly resistant, and calls for something drastic in the way of a remedy. One would think that paring the patches in winter and dressing with Stockholm tar would prove effective, but in many cases I have found the pests flourishing under the tar after it has dried, apparently appreciating the waterproof covering. Any correspondent who can recommend a really effective cure for woolly aphis would confer a boon on growers. I have heard of a painter's blow lamp being employed with good results.

PROSPECTS FOR PLUMS.

The next crop to send to market will be Plums. These have now got safely past the stoning stage, and there has been very little dropping. Czar and Monarch were badly attacked by brown rot, as shown by the brown and dried leaves and spurs. These have been removed as far as possible, much improving the appearance of the trees, and, it is hoped, saving the fruit from contagion. The Food Production Department recently asked for an estimate of the crop on a percentage basis doubtless as an aid to the fixing of prices. A full crop, 100 per cent., is considered to be four half-sieves to a tree. Thus a

FIG. 5.—FRUITS OF DAVIDIA INVOLUCRATA.

(See p. 12.)

25 per cent. yield is one half-sieve, and so on. Estimating by this method is not difficult, and would make for uniformity if adopted generally. Judged by this system, Rivers' Early Prolific comes out best in my orchards, with a 50 per cent. crop. Czar and Monarch are put at 25 per cent. and Victoria at 10. Pond's Seedling carries so little fruit as to make estimation impossible, whilst trees of President, Black Diamond, and Belle de Louvain are carrying no crops. So far no prices have been fixed for Plums, but there is little doubt that they will be announced before long, and it is anticipated that they will be high. *Market Grower.*

PROSPECTS OF THE VEGETABLE CROPS.

WE have now reached the middle of the season in what is probably the most important year of vegetable cultivation this country has ever known, and at this stage it may be useful, as well as interesting, to take stock of the condition of the crops and consider the results likely to be attained. My remarks apply chiefly to vegetables grown on heavy land; it may be expected that those cultivating lighter ground will have scarcely such favourable results. Amongst the many thousands who have attempted the cultivation of food crops for the first time, few have failed for lack of energy and enthusiasm, but the season has been a very trying one, for in addition to a prolonged drought following a period of cold north and north-east winds, pests and diseases have multiplied at an unusual rate and greatly taxed the efforts of growers in keeping their plants healthy and steadily progressive.

Still, on the whole, the results far exceed expectations, and the large majority of crops are quite as good, or even better than could be expected, especially on land newly broken up.

Many of our early crops of vegetables were brought forward under glass and the seedlings planted out later, a system which I find a great advance on sowing in the open. Many Peas and Beans were grown in deep boxes raised under glass and grown on in the open, a plan which I have recommended and adopted for some years past. These crops proved to be much earlier and heavier than those from plants sown direct in the open. Portable frames are amongst the most valuable and profitable means of producing early vegetables on mild hot beds of leaves, and have been used at Aldenham for this purpose for many years. Such vegetables as early Asparagus, Globe Beet, Turnips, Carrots, Cauliflowers, and Vegetable Marrows may be grown with the greatest ease and in the highest stage of perfection by means of these frames. Standard sized frames and lights should always be used.

With regard to the oft-debated question of manures I still pin my faith to well-decayed farmyard manure as being the best material for a good feeding basis for the majority of crops, and, secondly, to burned garden refuse. A grower cannot do better than utilise these valuable sources of plant food. Soot is one of the most useful fertilisers, not only for its stimulating action upon growing crops, but also for the way in which it acts as a deterrent to many insect pests, though I am afraid that even now there are large numbers of growers who fail to realise its great value. Of the use of lime little need be said, for most cultivators know its value as a soil sweetener and its destructive powers to pests and diseases.

Two or three fertilisers are worthy of mention for the beneficial work they accomplish during the free-growing period of crops, and they are especially valuable for leafy crops. Nitrate of soda and sulphate of ammonia are both quick-acting artificials, whilst for root crops the slower acting phosphatic manures play a similarly important part. The phosphates may be divided into two groups, (1) basic slag, which for heavy soil proves most useful; (2) superphosphate, which is best for light soils.

These artificials should be applied at intervals of about three weeks during the season of active growth, and I would suggest the application of 1½ oz. of sulphate of ammonia per square rod for leaf crops, and 2 ozs. of sulphate of potash for root crops per square rod.

My own observations are as follows:—

POTATOS. Notwithstanding the continued drought, Potatos in this locality are looking remarkably well; the very early varieties are lifting splendidly, and should rain come quickly and in a reasonable quantity the later plantings should produce heavy yields. One cannot urge too strongly the importance of planting either

Scotch or Irish "seed" tubers in England, for, even when once grown in the south, the difference is most marked; in almost every case I have carefully made the comparison. The value of sprouting the sets before planting cannot be too greatly emphasised.

ONIONS.—Probably the crop next in importance to the Potato is the Onion, and Onions should be far more largely cultivated than at present, as they are very profitable to cultivate, being always in great demand. This crop is disappointing in some districts, owing more especially to the unfavourable weather, but it is not generally unsatisfactory, and I know of large areas in which the plants have done remarkably well. Wireworms, leather-jackets, and the Onion fly have been very prevalent this season and caused a considerable amount of damage.

PARSNIPS.—Though Parsnip seed germinated somewhat badly the crop looks very promising, and should provide much valuable food for the coming winter.

CARROTS.—These, in many places, are not nearly so promising as last year, but with us they have never looked better.

BEET.—Like Parsnip seed, that of Beet germinated very irregularly, and in many cases the seedlings were badly attacked by the Turnip flea, the first time I remember any serious damage being done to this crop by the pest; in spite of all this the crops should be satisfactory.

SHALLOTS generally are particularly good, and the bulbs will make a fine substitute for Onions where the latter are a failure.

CELERY.—Young Celery plants in this locality have suffered badly from the Celery fly, the foliage being much disfigured, and this has caused a lot of labour in destroying the pest and removing badly affected leaves. Celeriac has suffered in the same way, but there is yet plenty of time for these valuable vegetables to produce splendid results.

PEAS.—These, with us, were never nearly so good as they are this year, though in some districts they are not so satisfactory. Practically the whole of our plants are grown in deep, well-prepared trenches, which is, in my opinion, the best method of cultivating Peas, whether early, mid-season, or late varieties.

BROAD BEANS are as good as Peas, and for the first time we have intercropped these with Runner Beans, which are promising also remarkably well. This method of intercropping is an interesting and profitable one.

CABBAGE.—Cabbages generally have been good, but I never remember prices for this vegetable ruling so high, in many cases for produce not of the best.

CAULIFLOWERS have been particularly scarce, and have realised very high prices. Autumn sown plants proved to be far and away better than those sown in early spring, producing finer heads, maturing earlier, and withstanding the cold, dry weather much better.

MUSHROOMS.—I have long been of the opinion that Mushrooms are a valuable food crop, and they should be grown wherever it is possible to procure horse-droppings for the making of the beds. All kinds of excuses are put forward for not growing this nutritious food, such as inexperience, and lack of facilities. Very little experience will teach anyone the direction in which success lies, and if no building is available, Mushrooms may be cultivated well in the open. The demand is nearly always larger than the supply, and good prices can always be relied on, and they are especially good at the present time. The old material from spent Mushroom beds forms one of the most valuable manures for general use in all branches of gardening.

VEGETABLE MARROWS.—By starting the plants early on mild hot beds in portable frames, Marrows are available from April until about the end of May, when the lights and frames may be removed; at that date the plants will be in full bearing when the majority of growers are just planting their specimens. These same plants will continue to bear profusely till the first frosts destroy them. This year we have grown Marrows more extensively this way, the results being highly satisfactory. All are urged by the Food Production Department to cultivate Marrows much more largely this season; many local food committees are recognising them as fruit for jam making, and the earlier Marrows intended for this purpose can be selected and ripened the better.

PUMPKINS are as valuable as Vegetable Marrows. When well grown and thoroughly ripened they constitute one of the best winter vegetables. The essentials to success are to grow them in a sunny situation, keep the roots well supplied with water, and elevate the fruits above the foliage to expose them as much as possible to the sunshine.

WINTER GREENS.—Unfortunately the seeds of many kinds of winter Brassicas germinated very badly in many cases, but let me urge the importance of filling every foot of vacant space with greens of some kind or another, choosing as far as possible those which are among the most hardy and prolific.

VARIETIES.—It is remarkable how varieties differ in their action according to the locality in which they are grown; a certain sort may do excellently in one place, and may prove unsatisfactory in another. The surest guide to the grower on this question is for him to observe what sort does well in his own district. *E. Beckett.*

GARDEN VARIETIES OF STREPTOCARPUS.

IT is questionable if any class of decorative plants, except Perpetual Carnations, has made so much progress within the past 30 years as the garden varieties of Streptocarpus. Some members of the genus had long before that time been introduced into this country, but they were rarely met with outside botanic gardens. The oldest of all is Streptocarpus Rexii, which was introduced in 1824. The foundation of the present day race was the red-flowered S. Dunnii, discovered in the Transvaal in 1884, and first flowered at Kew in 1886. Mr. Watson at once took advantage of this distinct species, and by crossing it with S. Rexii a very pretty hybrid, to which the name of kewensis was given, was obtained. Crossed with S. parviflorus, the result was S. Watsonii. Both these hybrids attracted a good deal of attention, and they were given First-class Certificates by the Royal Horticultural Society in 1887. A commencement having been made the improvement of these Streptocarpi was taken in hand by other raisers, the result being the production of the present-day race, which is in every way desirable. There is a wide range in colour from the purest white, through different shades of pink and carmine, to deep red or crimson, while in many the blue, violet and purple shades are very pleasing. The plants are also exceedingly floriferous. Besides the species above named, it is quite possible that other more newly introduced kinds have been employed by the hybridist.

After the certificates awarded to the Kew-raised forms, several Awards of Merit were given by the R.H.S. to the different strains of hybrids from other raisers. Messrs. J. Veitch and Sons were among the first to take these in hand; indeed, their strain was in 1891 given a similar honour to those varieties from Kew.

These Streptocarpi may be readily raised from seed, which, if sown early in the year and given much the same treatment as Gloxinias, will produce plants that will flower in the course of the summer. Unlike Gloxinias, they do not form tubers, therefore they should during the winter be given water enough to keep the soil slightly moist, but not saturated. *W. T.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

MUSHROOMS.—Plenty of Mushrooms should now be forthcoming from ridge-shaped beds in the open or beds in cool sheds. Make preparations for supplies from the end of September onwards. The manure for the beds should be collected and prepared during the present month, as the early beds should be spawned by the middle of August. The earliest beds may be made in a cool, sheltered shed if the Mushroom house is not considered large enough. It is not advisable to utilise the houses much before November, when beds are spawned then and early in December.

GENERAL REMARKS.—In times of drought a few moisture-loving vegetables may suffer, but the beneficial effect of the extra warmth imparted to the soil is observable for the rest of the season. When the soil is dry and hard, weeds are easily kept in check, slugs are comparatively harmless, and winter vegetables form sturdy, hardy growth. The old fashioned plan of puddling the roots of Brassicas prior to planting should always be practised in hot, dry weather. All that is necessary is to mix some soot with clayey soil and water and thoroughly coat the roots with the stiff puddle thus formed. If Broccoli plants remain crowded in the seed-beds for a few weeks only they will form long stems; therefore the sooner they are set in their final quarters the better. Savoys should be grown in quantity in both large and small gardens, and ground that is cleared of Potatos will be suitable for them. Kales should be finally planted about 2 feet apart each way, or the rows may be 2 feet 6 inches apart. Keep all growing crops liberally supplied with water so far as labour permits, and give the plants an occasional watering with liquid manure. The thinning of such crops as Onions and Carrots should be done finally, in order that after this date they may receive as little disturbance as possible. A good watering should always be given the rows before doing this work, followed by subsequent waterings as often as the soil is found approaching dryness. Early Potatos are developing rapidly, especially on sandy soils. Heavy rains will have disastrous effects on these advanced crops unless precautionary measures are taken, as many of the tubers will start into fresh growth. When supertuberation takes place much of the crop is spoiled, and this should be prevented by lifting the tubers early. Many crops are infested with grubs and insects. Frequently dusting the damp foliage with soot will have a deterrent effect, and is the safest and best remedy. A sharp watch should be kept for the Celery leaf miner from day to day, and all infested leaves must be picked off and burnt.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to Mrs DEMPSTER, Keele Hall, Newcastle, Staffordshire.

YOUNG POT VINES.—No useful purpose is served by retaining pot Vines when their fruit has been removed, as the house they have occupied can be utilised for ripening young pot Vines for next year's forcing. In the meantime the house should be thoroughly cleansed with warm, soapy water, and the bed put in order. There should be no difficulty in removing these Vines to a suitable house where they will receive the maximum amount of light and air, providing they have not been allowed to root through into the plunging material. It is not advisable to plunge the pots; indeed, it is a better plan to raise them a little above the bed, so that sunshine and air may reach the whole length of the canes, and, maybe, to a lesser extent, the roots. When growth is complete allow a free circulation of air, and on no account permit any lack of moisture. Syringe the Vines daily until the foliage changes colour. The laterals may be cut back if the main leaves are healthy, but not if they are damaged or destroyed.

FIGS.—Established Fig trees in borders which have been kept dry while ripening their first crop are liable to attacks of red spider. Now that the fruits have been gathered the syringe should be brought into use again. Thoroughly water the roots, and should the second crop be a heavy one, afford frequent applications of liquid manure. A top dressing of decayed manure will conserve the moisture, but it should only be applied when the borders are full of roots and the trees carrying heavy crops. Syringe the trees vigorously twice daily and keep the atmosphere moist by frequently sprinkling the paths and borders. Ample ventilation must be afforded early in the forenoon, but the house should be closed early in the evening. At no stage of growth should the atmosphere be cold and damp. Keep the shoots trained regularly to prevent overcrowding, and expose all parts of the trees to sunlight and air. Thin the fruits where necessary, preferably in various stages of development, otherwise there may be a glut of ripe fruit instead of a succession.

MELONS.—If the leaves on the plants from which the fruits are now being gathered are clean and healthy, such plants need not be discarded, because, with liberal treatment, they will produce an excellent second crop of fruits. Shorten back the growths and give the bed a liberal watering of diluted liquid manure. Syringe the plants lightly once or twice daily, according to the state of the weather, for, although Melons revel in moisture, syringing may be carried to excess. I prefer to obtain the necessary atmospheric moisture chiefly by syringing the paths, walls, and bare spaces frequently during bright weather. No time should be lost in setting out plants in narrow, shallow beds, or in pots, for autumn fruiting, as it is not an easy matter to obtain highly flavoured Melons from plants set out after this date, except in very favoured districts and favourable seasons.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

AUTUMN-FRUITING RASPBERRIES.—The comparatively dwarf variety Belle de Fontenay is developing flower trusses. From now onwards the weaker shoots should be thinned out, but not of the latest kinds, such as the Hailsham berry and November Abundance, for a little longer. I do not care to cut away any shoots that show for fruiting, for by grading these a better succession may be maintained. Keep the ground well hoed and watered if there is need of moisture, but the application of mulches is hardly necessary. These Raspberries need not be netted until early in September. Defer the staking and tying of the plants for a few weeks longer; I prefer to do this work early in August and put the nets on afterwards.

FRUITS FOR PRESERVING.—It is better to pick fruit for preserving when it is slightly under-ripe rather than over-ripe; very ripe Strawberries would be too soft for the purpose, and dead ripe fruit of any kind does not keep well when preserved, even when slightly more sugar is used. The flavour, too, will be better for being slightly tart. Fortunately most soft fruits are plentiful in gardens this season. Our Black Currant bushes never carried such heavy crops, notwithstanding they have the big bud pest; the fruits have all been gathered in these gardens. Other Currants, too, are clean and the bunches good; these fruits will soon be fit for use; in fact, we shall follow on with them at once. Our earliest Raspberries were picked on the 3rd inst., and the first big picking will be made and the fruits used for bottling before these lines are in print; the second picking will be used with the Currants. Of Strawberries, Keen's Seedling has again been our mainstay for preserving. The fruits require a lesser quantity of sugar than more acid varieties. Other berries, such as the Loganberry, the Phenomenal berry, and its near counterpart, the Newberry, are useful for dessert purposes, especially for breakfast. The Lowberry is distinct, with lustrous black fruits; this, too, is a very serviceable fruit for sending to table. The Kentish Cherry is with us carrying a good crop, but these fruits require to be gathered soon as birds are fond of them.

PUMPKINS FOR PRESERVING.—In view of the scarcity of late stone fruits we have grown Pumpkins of the giant type for the making of preserve. The plants are doing well, and several fruits are already set; with attention to watering there should be a good crop at the end of the preserving season. Pumpkins for jam making should be well matured. Even if not used for preserving Pumpkins and Gourds keep for a long time, and may be used instead of Apples where these are scarce. I do not intend to crop my Pumpkin plants heavily; I shall be satisfied with one good fruit on each. I give preference to Pumpkins over Vegetable Marrows, as the jam from the latter is not so good from the point of colour, although possibly firmer when made of well matured fruits.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

ROSES IN POTS.—Climbing Roses growing in pots have passed out of flower, and attention must be paid to next year's flowering growths. Plants which show signs of exhaustion should be cut back hard to encourage new shoots to develop from their bases. Those which are growing satisfactorily should be relieved of all the old flowering wood in order that the young growths may have plenty of room to develop. Carefully examine the stakes of each plant, and replace old ones with new where this is necessary. The plants should be plunged in a bed of ashes in a sheltered position out-of-doors until they are required for forcing. Syringe them vigorously in the evening; should aphis attack the young growths use an insecticide. Water the roots with stimulants on two or three occasions weekly.

SOUVENIR DE LA MALMAISON CARNATIONS.—These Carnations must almost be classed as perpetuals, and preparations for layering shoots should be made at once to obtain strong plants before the winter. Prepare a fine compost consisting of loam, leaf-mould, and sand. Place on the border a shallow frame in which to layer the plants. The fresh soil should be at hand and used around the plants as they are layered. The oldest plants should be used for layering, reserving the best of the one-year-old specimens for potting into larger receptacles. These plants will produce the main supply of flowers next season. When layering is finished for the day the plants should be thoroughly soaked with water, and the lights placed on the frames. Shade them from bright sunshine, and keep the frames fairly close until the plants are rooted. They should then be gradually accustomed to cooler conditions. Pot on one-year-old plants as soon as possible, using 8-inch or 9-inch pots. A suitable compost is formed of rich, fibrous loam, manure from a spent Mushroom bed, wood ash, crushed bones, and coarse sand, in suitable proportions. Pot moderately firmly, and place the plants in a cool house. Keep them shaded for a few hours during the hottest part of the day till they have recovered from the disturbance of repotting, and water the roots with extra care.

ASPARAGUS SPRENGERI.—This exotic Asparagus is another useful plant for furnishing foliage for all kinds of decorative work. It may be grown as advised for Smilax, or in pots and baskets. It makes a handsome plant grown in hanging baskets for the conservatory or greenhouse. When well established it is scarcely possible to give the roots too much water during the summer.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

ONCIDIUM.—Many of the cool-growing Oncidiums, such as O. concolor, O. crispum, O. Marshallianum, and others, after a short period of rest, will begin to push forth new growth, and about this time will probably be fit for repotting. The majority of these species produce their flowers in pendulous racemes and are best grown in shallow pans and suspended from the roof-rafters in the warmest part of the cool division. A suitable rooting medium consists of equal proportions of chopped Osmunda- or A 1 fibre and half-decayed Oak-leaves. These plants resent having a large amount of compost about their roots, therefore moderate sized pans should be used, with a good supply of drainage material. Oncidium tigrinum grows best if afforded much the same treatment as for Odontoglossum crispum, and any repotting of this species should be done when the new shoots are about 2 inches long. Frequent root disturbance is not desirable. Water should be afforded with moderation; while the plants are at rest, only sufficient moisture need be given to keep the pseudo-bulbs plump. Oncidiums of the warmer-growing section, including O. Lanceanum, O. luridum, and O. carthagenense may also be afforded fresh rooting material as they reach the desired condition. A light position in the warmest house is most suitable to their requirements. When in active growth the plants should be given liberal supplies of water at the roots, and sprayed freely on bright days, but during the resting season water should be applied very sparingly, as the fleshy leaves are capable of withstanding a reasonable amount of drought without injury. When an excess of moisture is applied the leaves become spotted and rot off.

EPIDENDRUM.—Many Epidendrums have little garden value, but certain species are well worthy of cultivation. The winter-flowering E. vitellinum majus is one of the most useful and decorative, as it produces bright scarlet flowers during the winter. It succeeds best in the cool house, and should be repotted or top-dressed when new growth commences. Place the plants in shallow pans provided with ample drainage, and suspend them from the roof-rafters, or place them on the stage in a light position. Afford water sparingly during the early stages of growth, but when root-action is vigorous give liberal supplies of moisture until the pseudo-bulbs have matured. During the resting season afford only sufficient water to keep the growth firm.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

IRISES.—Some years ago I gathered most of the summer-flowering Irises into a long border, where they have become close enough to form a mass of vegetation. The display of flowers this year has been a revelation of the great beauty of all kinds. Even those that could only be described as nondescripts are beautiful in large groups.

ROSA.—The early-flowering Rosa alpina will soon be displaying its brilliantly coloured elongated hips; it is an object of interest at all times, being distinct in foliage and wood. The plants are at their best when allowed space to develop into large bushes, which established specimens do by means of suckers. The form we grow is pyrenaica. Another shrubbery Rose of much effect at the present time is Rosa rubrifolia. When well established this species may be pruned hard at short yearly intervals, when strong shoots furnished with fine decorative foliage will develop.

GILIA CORONOFOLIA.—It is important to make an early sowing of this brilliantly coloured species. The seeds remain in the soil for a long time before they germinate, and the growth of the plants in their early stages is also very slow, so that strong flowering plants for another year can only be had by sowing now. They do best grown on in pots, shifting them as required; the final pots need not be larger than 5 inches diameter. It is essential to keep them growing slowly, just like Humeas, and, like Humeas, they are apt to die unless very carefully managed. The last named plant should also be sown about this time.

CLEMATIS MONTANA.—This beautiful early flowering species will now, or soon, need attention in pruning and thinning the shoots that have flowered. Both the type and the rose-coloured variety are perhaps seen at their best when trained to hang over and below balconies. The variety has been very fine here trailing over large stones on a rockery, the shoots being kept in position by placing small stones on them, the stones being hidden by the foliage of the plants.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER** 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 41, Wellington Street Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, JULY 16—
Roy. Hort. Soc. Comm. meet, and National Carnation and Picotee Soc. combined show, at the Drill Hall, Buckingham Gate, Westminster.

THURSDAY, JULY 18—
Croydon Hort. Soc. Vegetable Ex. in Park Hill Recreation Ground, Croydon.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 65.7

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, July 11, 10 a.m. Bar. 29.9, temp. 59.5°. Weather—Raining

The R.H.S. Scientific Committee.

The Scientific Committee of the Royal Horticultural Society is just fifty years old. It was originally called together to "promote and encourage the application of physiology and botany to purposes of practical culture" (we quote from a circular letter sent out in March, 1868), "and to originate experiments which may assist in the elucidation of horticultural subjects." Of the original members of the Committee only one remains, Mr. J. G. Baker, F.R.S.; all the rest have passed away. It included men foremost in their own spheres—De la Rue, F. A. Abel, J. H. Gilbert, A. Voelcker, Chas. Darwin, Herbert Spencer, Sir Joseph Hooker, George Bentham, Robert Fortune, Frederick Welwitsch, Robert Hogg, Maxwell T. Masters, Wilson Saunders, and G. F. Wilson, the maker of Wisley. The President of the Society, the Duke of Buccleuch, was first chairman; the Rev. Myles Berkeley, one of the most eminent students of plant diseases, the first secretary. The first meeting was held on April 20, 1868, when the secretary outlined a policy which has been in the main the policy which has actuated the Committee ever since. He foresaw the need for the Society undertaking its own experiments and the establishment of an experiment station for horticulture, but warned the Committee that that was not possible then. Questions of morphology as well as physiology, of nomenclature, information of general horticultural or more purely botanical interest, botanical geography were all deemed proper subjects for the consideration of the Scientific Committee, and the reading of papers and the holding of conferences upon various plants of horticultural interest were all contemplated.

Almost immediately after its establishment experiments upon certain plant diseases were set afoot, and the attacks of insect pests frequently formed the subject of comment.

Allowing for change of outlook and advance in knowledge, the policy and the method outlined at the first meeting have remained almost the same ever since. Men eminent for their knowledge have constantly allowed their names to be added to the Committee as time has passed, and others have dropped out, and the proceedings of the Committee form a series of records which no one conducting any inquiry into the science of horticulture can afford to neglect. Like all other bodies, the Committee has had its ups and downs, but even in its least active times the attendance records show how men like the late Dr. Masters, the late Sir Joseph Hooker, and the Rev. Geo. Henslow kept the meetings going and carried out the functions for which the Committee was constituted.

It is within the recollection of many of its present members how, about twenty years ago, the Committee was largely increased and entered upon a renewed period of activity, and many of its present members, under the active chairmanship of the late Dr. Masters, took part in assisting its progress.

Another name long and actively connected with the Committee also calls for mention—that of the Rev. Prof. Henslow, who was secretary for some twenty-five years.

The efforts of the Committee have done not a little towards stimulating interest in the cultivation of plants for their own sake, and in bringing about some sort of uniformity of method in plant naming, while never from its inauguration, and its early efforts in support of Hooker's administration of Kew, when Kew appeared likely to be alienated from its purpose, did the Committee cease to bear in mind, and when opportunity offered to urge, the establishment of a station for scientific investigation under the Society's ægis. This was accomplished in 1907, when the funds of the Society warranted the step, which, not for lack of will on the part of the Council, had been only looked forward to for forty years. The present Committee is an exceptionally strong one, and includes not only a large number of scientists interested in the particular problems of the garden, but representatives of trade firms and many prominent gardeners, both amateur and professional. The chairman, Sir W. Thiselton-Dyer, is an old and valued member, and the list of vice-chairmen includes the names of Sir Daniel Morris, Lieut.-Col. Sir David Prain, and Mr. E. A. Bowles. In recent years Mr. Bowles has more often presided at the meetings, and both his services and those of the hon. secretary, Mr. F. J. Chittenden, have been invaluable to the Committee.

The Drought.

Gardeners everywhere, but particularly those who cultivate light soils and who are unable to obtain adequate supplies of manure, have experienced a difficult time, and it will require all their ingenuity to secure anything like reasonable returns from many of their crops. The long spell of drought which now appears to be breaking up has discovered the lack of resource in light and incompletely manured soils, and nothing is more striking at the present time than the state of garden crops in such soils in comparison with that of those in similar but well-manured soils. In the one case the crops are "doing nothing"—they remain quiescent, and are unable to make growth in the absence of moisture. Where, however, a moderate dressing of manure was put under the site of the crop, the drought so far has had but little effect, and some of the finest Peas which we have ever seen are growing and flourishing under these latter conditions. For our part, we are convinced that where—as is only too frequently the case nowadays—supplies of manure are deficient, it pays far better to spread the manure more densely beneath the site of each crop than to distribute it uniformly over the ground and then to dig it in.

Experience with these poor, light soils shows also that watering is of but doubtful value—in some cases, of course, it must be done, as, for example, with Tomatos, but constant working of the soil pays far better in the long run. In no direction has the drought done more serious harm than in that of the soft fruit crops. The promise was bad, but the performance of these crops is worse even than the promise. This is particularly noticeable in the case of the Raspberry, which, like the Red Currant, bade fair to produce a good crop. Nevertheless, in the continued absence of rain, the berries failed to swell; such as ripen are of poor size, and will give the pickers in commercial plantations very tedious work. It is therefore but just that the Ministry of Food, on the recommendation of the Board of Agriculture, should have increased the price from £37 to £44 per ton. The need for jam is so great that everyone who has fruits to spare should endeavour to supply his surplus to the Controlled Jam firms, on whom the responsibility rests for providing jam for the Navy and Army. The names of these firms may be obtained on application to the Ministry of Food, or to the Food Production Department. It is the more urgent that this course should be adopted on patriotic grounds, because of the dearth of Plums—which fruit is in normal years the main supplier of the jam pot.

Those who have fruit which they are prepared to dispose of in this way should communicate with the latter of the Departments named above, if they require assistance in disposing of their surplus. The dearth of cultivated fruit makes it imperative that the systematic collection of wild fruit, such as Blackberries, should be undertaken. Arrangements for this col-

lection are, we understand, now being made, and gardeners should be able to lend valuable assistance to the County organisations undertaking the work of collection, and in particular their knowledge of packing and despatching to market should be specially valuable. If sufficient wild fruit is to be obtained to make up for the lack of cultivated fruit, the help of everyone in country districts, and that of many from urban districts, will be required, for the quantity of Blackberries which should be gathered may be estimated at many thousands of tons. Fortunately, there is a brave showing of blossom, and with the welcome rain of the past few days there should be an abundance of ripe fruits.

WALKER PRIZE AWARDED TO PROF. J. LOEB.—The Walker Grand Prize, given every five years for scientific investigation or discovery in natural history first made known in the United States, has been awarded by the Boston Society of Natural History this year to Prof. JACQUES LOEB, of the Rockefeller Institute, as a recognition of his works, covering a wide range of inquiry into the basic concepts of natural history. The prize is a thousand-dollar Liberty Bond.

HARVESTING THE FLAX CROP.—Three thousand women and girls have been sent to Somerset and Northants during the past week to pull flax for the Government. They have been recruited and despatched by the Women's National Land Service Corps.

NATIONAL DIPLOMA IN HORTICULTURE.—The results of the 1918 Examinations for the National Diploma in Horticulture, held at the Royal Horticultural Society's Gardens, Wisley, in June, are as follows:—Section I. General Horticulture.—JOHNS, W. H., 2, Bean Street, Waterford; KING, Miss G. D., Groton Rectory, Ellsworth; RAMSBOTTOM, J. K., 61, Emmedale Road, Richmond, Surrey; JOSHUA, Miss I. H., 7, Waterloo Place, Kew Green, Surrey. Section VIII. Horticultural Teaching.—JOHNS, W. H., 2, Bean Street, Waterford. The following candidates satisfied the examiners' requirement in the Preliminary Examination:—JONES, Miss D. R., The Bungalow, Battle Abbey Lane, Heath, Southampton; SMALLBONE, Miss E. L., Homerton College, Cambridge; HAKE, Miss L. W., 43, Gillingham Street, Eccleston Square, London; BENNER, J., 8, Waterloo Place, Kew Green. These candidates are accordingly eligible to take the Final Examination in 1919 if they have then spent six years in regular garden work, or as soon thereafter as they can satisfy this requirement.

ACCIDENT TO CAPT. A. W. HILL. We regret to learn that Capt. ARTHUR W. HILL, Assistant Director, Royal Gardens, Kew, met with an accident about ten days ago. He was thrown from his horse, in Richmond, and remained unconscious for several hours. We are, however, very glad to be able to state that the consequences of the accident have not been so severe as was anticipated at first, and his many friends will be pleased to know that Capt. HILL is able to attend to his business again, though still suffering from shock.

AMERICAN FLORISTS' CARE OF WOUNDED SOLDIERS.—Thirty-eight thousand florists in the United States have pledged themselves to keep the base hospitals supplied with fresh flowers.

TRAFALGAR SQUARE FLOWER FAIR.—Lord BERESFORD has sent a letter to the Council of the Royal Horticultural Society thanking the Society for the support given in connection with the Flower Fair held recently at Trafalgar Square. He also asks that an appreciation of the services rendered by them be tendered to Mr. BISSET and Mr. JORDAN, two of the Society's employees, who had entire charge of the enclosure containing the nurserymen's exhibits and put up all the staging. Lord BERESFORD states that 43,000 people paid for admission to the fair, and despite unfavourable weather, the sum of nearly £9,000 was received on behalf of the British Ambulance Service with the French troops.

SUMMER PRUNING OF FRUIT TREES.—In the case of standard fruit trees in orchards, summer pruning is not necessary, nor would it be practicable; but for bush, pyramid, and other trained trees grown in the garden under certain limitations of space, summer pruning is essential for the maintenance of fruitfulness and the production of heavy crops. Stated briefly, summer pruning consists in shortening the current year's growths so that the natural forces thus checked may be diverted to the production of fruit buds. The removal of growth and leaves allows more light and air to enter the tree to mature or "ripen" the wood and buds. The condition of the trees, the time of year, the weather, and the locality, must all be taken into account in determining the extent of the summer pruning necessary. Young trees carrying poor crops usually make free growth, and in such cases it would be unwise to shorten such free growth by two-thirds, as this would only cause other shoots to develop, and the end in view would be defeated. In such cases a moderate reduction of growth would suffice, thus allowing the upper buds to act as safety valves, and permitting the development of fruit-buds at the base. This season the prospect of secondary growth is unusually great if a period of wet weather follows the long-continued drought, therefore growths should not be shortened so severely as usual, and the pruning period should be extended over a fortnight or three weeks. The middle to the end of July is generally the

(See p. 12.)

best period for the summer pruning of Apples, Pears, and Plums, shortening the shoots to five or six leaves.

PRIVATE GARDENERS AND WAR SERVICE.—A copy of the following memoranda, issued by the Controller of Horticulture to Agricultural Executive Committees, has been received by the Royal Horticultural Society: "The question as to the position of private gardeners who are engaged on work of food production which may reasonably be considered to be of national importance has been under consideration. In dealing with such cases the following points should be considered by Agricultural Executive Committees. It is of no importance whether a man was registered under the Registration Acts of 1917 and 1918 as a gardener or otherwise who was not at the time of registration occupied in food production. The occupation on May 28, 1918, is the ruling fact. The essential point to be considered is not the acreage under cultivation, but the man's occupation, the value of that occupation to food production, and the volume of produce depending on the exercise of the occupation. If the Committee is satisfied that a man is wholly or mainly engaged in the production of food of a kind and quantity to constitute national importance, they may issue a voucher under the Agricultural Exemptions Order, 1918, protecting him from military service. It is also to be clearly understood that if a man has already been called up the calling up notice will not operate and should be cancelled if an Agricultural Executive Committee decides that he is eligible for a voucher under the Order."

BOOKS AND THE LUXURY TAX.—The Council of the Royal Horticultural Society has addressed the following Memorandum to the Committee set up by the Government to prepare a scheme for the taxation of luxuries: "The President and Council of the Royal Horticultural Society, representing upwards of 13,000 persons in this country, many of them deeply interested in scientific and research work, beg to submit the following Memorandum on the alleged inclusion of books among luxuries: (1) To encourage education and tax books appears to us to be giving with one hand and taking away what is given with the other; (2) scientific and research work are largely dependent on the study of books and printed literature, and if we are, after the war, to be in a condition to rival German scientific work it can only be done by the diligent study (amongst other things) of books; (3) the improvement and extension of practical gardening, which must to such a great extent be relied on for securing larger food crops, depend on a free circulation of books devoted to the subject, and it is only by such books that the results of scientific research are made available to the manual worker. We therefore hope that the report of the inclusion of books within the operation of the Luxury Tax may be reconsidered."

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

HARDENING TENDER PLANTS.—The editorial article on page 6 is well worthy of careful perusal by those who have plant houses under their charge. The reduction of fuel will very likely cause many tender plants that have been generally grown to almost if not quite disappear from gardens. Exotics may retain their health in a lower temperature than that in which they have hitherto been grown, and it is quite possible that some interesting features may be recorded. I have been told of a Stephanotis which was annually wintered in a greenhouse from which frost was just excluded, and the plant was said to flower freely each year. A very important portion of the article in question is where attention is called to the fact that even tender plants will submit to relatively low temperatures, provided they are grown as hardy as possible in summer and autumn. The hardening off of tender plants before they are turned out-of-doors or removed to cooler houses is very general in the spring, especially in the case of bedding plants. This same practice may well be followed as you advise during summer and autumn in order to prepare the plants for a lower temperature in winter. A free circulation of air, and the reduction of atmospheric moisture will tend to ripen the wood, so that the plants will be less affected by cold than would be the case if the growths were in a soft, unripened condition. Another point to bear in mind when plants are subjected to an unduly low temperature is to keep the soil as dry as it reasonably can be without unduly distressing the roots. Any watering that is absolutely necessary should be done in the morning of fine days, so that plenty of time is allowed for the superabundant moisture to dry up before evening. Should frost enter the house the roof should, if possible, be covered up, so that the plants are in darkness till they are thawed gradually. *W. T.*

THE PRICES OF VEGETABLES.—It may interest *W. T.* and others of your readers to know that not all growers are "profiteering" in Lettuces. I sent to one of the London markets recently 51½ doz. Cos Lettuce and 13 doz. Cabbage Lettuce. The majority of the Cabbage Lettuce would weigh about ½ lb., and 4 to 5 doz. would fill an ordinary salesman's hamper (not flats), and 3 doz. Cos to each hamper, so they were not a small sample. My returns to hand gave me 10d. per dozen (gross). After deducting railway charges and salesman's commission, I had the munificent sum of about 5½d. per doz. This return, with the present price of labour and high cost of requisites, leaves but little for the grower. *Amateur Market Grower.*

SOCIETIES.

NATIONAL ROSE.

JULY 4.—In brilliant weather the National Rose Society celebrated Independence Day by holding a very successful exhibition at the Royal Botanic Gardens, Regent's Park. A schedule of forty-eight classes was provided, and the usual trophies and pieces of plate were offered for competition as in former years. The exhibition was in aid of the funds of the British Red Cross Society, and was under the special patronage of her Majesty Queen Alexandra, who visited the show and spent a long time inspecting the Roses. She was accompanied by Sir Dighton Probyn, the Hon. Charlotte Knollys, Hon. Violet Vivian, Miss Willmott, Messrs. E. J. Holland (president), Courtney Page (hon. sec.), and Chas. E. Shea.

The tents were crowded with members and visitors, including a large number of wounded soldiers.

NEW ROSES.

As in previous years, one tent was set aside for new Roses. The Committee made the following awards:—

GOLD MEDALS.

Golden Ophelia (H.T.).—A very beautiful Rose, of moderate size, shapely and bright. The colour is light golden, and is intensified in the buds. The stems are long and stout, dark hued, and furnished with very dark foliage. A lovely variety for garden and decorative purposes, and said to be suitable for growing in pots. Raised and shown by Messrs. B. D. CANT AND SONS.

Colonel Oswald Fitzgerald (H.T.).—A very handsome variety, of vigorous growth. The flowers are of good size and tea scented; the colour is brilliant crimson-scarlet of an exquisite and attractive shade. The stems are long, and the leaves dark hued. Said to be perpetual-flowering and suitable for all purposes. Raised and shown by Messrs. ALEX. DICKSON AND SONS.

Pax (H.M.).—This is a very free-flowering hybrid Musk variety, with dark stems and foliage; the semi-double flowers are about 4 inches across, cream-white, with a central group of golden stamens and anthers. It is described as good for garden, bedding, and massing, and flowers from May to October. As shown it was grown on the Dog Rose stock. The individual blooms have foot-stalks about 4 inches long, consequently the branching clusters are most effective and graceful. Raised and shown by Rev. J. H. PEMBERTON.

Lamia (H.T.).—Another addition to the orange-flushed Roses. The semi-double blooms are exquisitely elegant, and the buds long; the stems and foliage are very dark, and form a fine setting for the gorgeous blooms. The colour is orange over yellow, and the orange is very deep and rich on the backs of the outer petals. Lightly tea-scented, free-flowering, and good for garden decoration. Shown by Mr. WALTER EASLEA.

CERTIFICATES OF MERIT.

Mrs. C. V. Haworth (H.T.).—A glorious and gorgeous semi-double variety, eminently suitable for garden decoration and bedding. It is difficult to adequately describe the colouring of the broad petals, as deep gold shades from the centre to amber and pink, and the boss of golden stamens and anthers add to the fine effect. Foliage dark and glistening. This Rose attracted very much attention. Raised, and exhibited for the first time, by Messrs. ALEX. DICKSON AND SONS.

Chameleon (H.T.).—As a decorative Rose this variety is of great promise. The colour is light orange and deep pink, and these shades intermingle in a most subtle and attractive manner. Some expanded flowers develop more pink, others show more orange shading, but all are beautiful, and the effect is gorgeous. As a decorative variety it has a great future, but for bedding purposes it may not be such a success, as the older and rosy flowers, if numerous, would reduce the effect of the orange glow in younger blooms. Raised and shown by Messrs. ALEX. DICKSON AND SONS.

Mrs. H. D. Greene (H.T.).—A very free-flowering variety, fragrant and shapely. The colour is soft rose with flushing of orange fawn, but this brighter shade seems to disappear as the flowers grow older. The buds are charming; stems and foliage very dark. Shown by Mr. WALTER EASLEA.

Dr. Joseph Drew (H.T.).—A deliciously fragrant Rose, with broad-petalled and bright, pearl-pink blooms borne freely on stout stems furnished with dark foliage. Raised by Mr. COURTNEY PAGE, and shown by Mr. WALTER EASLEA.

Lady Beatty (H.T.).—A particularly vigorous variety, suitable alike for garden or exhibition purposes. The foliage is very handsome, deep green, and the large-petalled flowers are sweetly fragrant. The colour is pale pink, with rosy suffusion at the edges of the petals, and a soft yellow glow at the bases. The flowering stems are long and stout. Raised by Mr. W. R. CHAPLIN and shown by Messrs. CHAPLIN BROS.

Edith Cavell (H.T.).—A faintly fragrant bloom of large size, with broad petals and pointed buds. The variety was obtained by crossing Frau Karl Druschki with St. Helena. The cream-white blooms are borne on long, stout stems, and the foliage is large and deep green. Raised by Mr. W. R. CHAPLIN and shown by Messrs. CHAPLIN BROS.

Independence Day (H.T.).—A rather small but shapely and scented variety, of medium habit, and suitable for bedding and for decoration: an ideal buttonhole Rose. The colour is rich orange-tinted yellow with a rosy flush on the recurving margins of the petals. Raised and shown by Messrs. BEES, LTD.

Mrs. Walker (H.T.).—A vigorous Rose of deep and bright velvety-crimson colour, semi-double, handsome, and lightly scented. It has handsome green foliage, appears to be very free-flowering, and is said to be perpetual blooming. Raised and shown by Messrs. FRANK CANT AND CO.

The Premier.—A distinct variety, obtained by crossing Rosa lucens with (probably) Miss Alice Rothschild. R. lucens is said to be mildew-proof, and in this respect The Premier has, so far, the good quality of its parent species. The variety is strong in growth, a pillar Rose, with light green foliage and clusters of semi-double blush flowers, each bloom about 1½ inch across. Raised and shown by Messrs. PAUL AND SON.

OTHER NOVELTIES.

Molly Bligh, shown by Messrs. ALEX. DICKSON AND SONS, is a vigorous H.T. variety, of excel-

lent form and good size; the colour is deep rose-pink, with an orange glow at the base.

The single H.T. variety *Irish Afterglow*, shown by Messrs. ALEX. DICKSON AND SONS, is vigorous and free flowering, and should be suitable for bedding and very useful for home decoration.

Mr. ELISHA HICKS showed a beautifully fragrant H.T. variety named *Mrs. Elisha Hicks*. The flowers are large and shapely, almost white, but with a pale blush-pink suffusion.

Golden Gem, shown by Messrs. FRANK CANT AND CO., is a neat little Rose that has bright orange shading on the outer petals of its buds, but opens a bright, pink-flushed yellow colour.

Lilian Moore (H.T.).—A vigorous H.T. variety, of moderate size and excellent form, coloured deep rich cream, with a suggestion of pink. Shown by Messrs. HUGH DICKSON, LTD.

Remarks on the Nurserymen's and Amateurs' Classes will be published in the next issue.

SOUTHAMPTON ROYAL HORTICULTURAL.

JUNE 26.—This society was again favoured with fine weather for its Rose show, which was held on the 26th ult. in the beautiful grounds attached to South Stoneham House, the residence of Ellen Lady Swaythling. The attendance, over 10,000, was a record since the Westwood Park days, the gate money amounting to over £500.

The show was rather disappointing in the matter of entries, but what was lacking in quantity was made up in quality. Mr. ELISHA J. HICKS carried all before him winning the 1st prizes in the open classes, and securing for the second time the open Challenge Cup. He also won the Medal offered for the best bloom in that division with the variety Charles E. Shea. Messrs. D. PRIOR AND SON were placed 2nd in each case. The Cup open to amateurs was won by Dr. LAMPLOUGH, who showed 15 fine blooms; 2nd, Capt. KIRBY SCARD, whose exhibit gained only two points fewer. This latter gentleman won the Silver Medal offered for the best bloom in that division with a fine flower of Mildland Grant. Mr. E. M. BURNETT, Westwood Road, was the most successful exhibitor in the local classes; he won seven 1st prizes and two cups. Mrs. BURNETT was equally successful in the Ladies' Classes. Messrs. W. H. ROGERS AND SON, LTD., and B. LADHAMS, LTD., were both awarded Gold Medals, and Mr. E. WITTS a Silver Medal for non-competitive exhibits.

SCOTTISH HORTICULTURAL.

JULY 2.—The monthly meeting of this Association was held at 5, St. Andrew Square, Edinburgh, on this date, Mr. R. Fife, President, in the chair.

Mr. W. Cuthbertson gave an address on "Early Potatos," illustrated by specimens of Sharpe's Victor, May Queen, Midlothian Early, Epicure, America (a new variety), Eightyfold, Edzell Blue, and others grown in Yorkshire, Ayrshire, and Edinburgh. Mr. Cuthbertson stated that the earliest Potatos on the market came from the Canaries, followed by those from the Channel Islands. The earliest grown on the mainland were produced in the Penzance division of Cornwall, but the biggest early Potato area in Britain was in Ayrshire, where some 7,000 acres were grown for the early market, and are being marketed now. Mr. Cuthbertson gave an interesting account of the origin of many of the varieties. He referred to the need for new varieties of early Potatos resistant to wart disease. Varieties such as Edzell Blue, Resistant Snowdrop, America, and A1 were immune, but were not available in sufficient quantities required for seed purposes in the infected areas in England. He pointed out how important an industry to Scotland the growing of seed Potatos was, and suggested that it ought to be fostered more than it has been by such agencies as the Scottish Horticultural Association and the Scottish Board of Agriculture. He thought the time was ripe for the holding of a national Potato show in Edinburgh every year, with classes open to allotment holders, gardeners, seedsmen, and farmers.

TRADE NOTES.

"TESTING OF SEEDS ORDER, 1918."

THIS Order came into force on July 1, 1918, and supersedes the Order of 1917, which is now revoked. Consequently, the provision that particulars are not to be given unless demanded by a purchaser, and not even then in the case of small packets, is no longer in force. The new Order provides that no person is to sell or expose for sale for sowing, or keep deposited in any place for the purpose of sale for sowing, any of the seeds scheduled in the new Order, unless a sample has previously been tested, either by the seller or on his behalf by one of the Government Testing Stations.

Furthermore, no one must sell or expose for sale for sowing any of the scheduled seeds unless certain particulars are given, but particulars do not have to be published merely in respect of seeds kept deposited for sale, although, as above stated, these must be tested. These particulars have to be given to the purchaser in writing at or before the time of sale or delivery. For this purpose they can be given in any form that the seller prefers as, for instance, in an invoice or a printed catalogue or price-list. Also, in the case of seeds exposed for sale, a copy of the particulars must be conspicuously exposed on, or in connection with the seeds. The particulars required by the Order are too lengthy to enumerate, but they include the following:—

1. Name and address of seller.
2. The kind of seeds (also, in the case of cereals, Clovers, and Sainfoin, the name of the variety).
3. The percentage by weight of pure seeds. (This, however, need not be stated in the case of cereals, while as regards field or vegetable seeds, it will be sufficient if the percentage by weight of pure seed is stated to be not less than 97.)
4. The total percentage by weight of certain injurious weed seeds, namely, Docks, Sorrels, Wild Carrot, Yorkshire Fog, and Soft Brome grass. (This, however, need not be stated in the case of cereals.)
5. The percentage of germination by number to be ascertained by a germination test. (In the case of cereals or vegetable seeds, however, it is sufficient to state that the percentage is not less than the Government standard mentioned later.)
6. The month and year in which the test was made, unless made within six months of the date of sale or exposure for sale.

Other details have to be given in the case of Clovers and grass seeds as to the presence of Dodder or Burnet, the proportion of hard seeds, the respective proportions of mixtures, and the country of origin (England, Scotland, Ireland and Wales being treated as different countries for this purpose). The Government officials have power to take samples of the seed, with the right for the seller to appeal to a combined test of the three Government Stations if desired. The Order does not apply to a sale of seeds "as grown" if the seeds are not bought by the purchaser for the purpose of his own sowing nor does it apply to a sale for delivery outside the United Kingdom. Various provisions are inserted as to the size of samples to be taken, and useful definitions are added as to the technical meaning to be attached to the words "germination" and "pure seed." A scale of latitude is also laid down in connection with germination tests, and also as to the proportion of injurious weed seeds. The following schedule shows the seeds to which the Order applies, and also gives the Government standard of germination in connection with cereals and vegetable seeds:—

SCHEDULE.

Kinds of Seeds of which the Sale and Exposure for Sale is Regulated.

PART I.

Perennial Ryegrass, Italian Ryegrass, Meadow Fescue, Cocksfoot, Crested Dogstail, Timothy. Under whatever trade names sold: Red Clover, Alsike Clover, White Clover, Crimson Clover, Trefoil, Lucerne, Sainfoin.

PART II.

Standard of Germination: Wheat, 90; Barley, 90; Oats, 85; Rye, 80 per cent.

PART III.

Tares or Vetches, Field Turnip, Swede, Rape, Fred Cabbage, Field Kale, Fred Kohl Rabi, Mangel.

PART IV.

Standard of Germination: Pea, 75; Dwarf and Broad Beans, 80; Runner Beans, 65; Garden Turnip, 85; Garden Cabbage, 75; Garden Kale, 75; Garden Kohl Rabi, 75; Brussels Sprouts, 75; Broccoli, 75; Cauliflower, 70; Carrot, 60; Parsnip, 50; Beet, 100; Onion, 65 per cent.

INCREASED PRICES FOR SOFT FRUITS.

THE Ministry of Food has increased the price of pulped Raspberries, from July 5 onwards, from £37 to £44 per ton, placed on rail at the growers' nearest railway station. The increased price does not apply to stalked fruits, or to any supplied before July 5, but contracts made for the delivery of pulped Raspberries after July 5 are now cancelled.

The Ministry has also made an Order allowing growers of Black Currants to make an additional charge of £6 per ton for fruits stripped or "strigged" by hand for the jam manufacturer.

NURSERYMEN AND MARKET GARDENERS AND WAR SERVICE.

THE Secretary of the Royal Horticultural Society has received from the Controller of Horticulture the following Memorandum to Agricultural Executive Committees relative to the issue of vouchers to nurserymen and market gardeners:—

"Some doubt appears to exist as to the position of men engaged in market gardening in cases where flowers are grown as intensive crops. The Department desires to draw the attention of the Executive Committees to Paragraph 2 (a) of the Memorandum dated 25th ultimo (No. C.L. 70 L.H.), which governs all such cases and requires an Agricultural Executive Committee to consider whether a man in the trades above mentioned is occupied in the production of food of a character and quantity of national importance. Thus, where a market-grower is mainly devoted to the production of food of a character and quantity which is of national importance, and the growth of flowers forms only a subsidiary business during a few months of the year, when food stuffs cannot be grown, it is within the discretion of the Agricultural Executive Committee to give such a man a voucher."

MESSRS. ELLWANGER AND BARRY.

THOSE who have had business with the leading American nurserymen will be interested to learn that a report is current to the effect that the firm of Messrs. Ellwanger and Barry, of Rochester, N.Y., is to be dissolved. This firm's nursery is the oldest in the Rochester district, and the reason given for the dissolution of the firm is the encroachment of the city upon the nursery ground.

COUNCILLOR J. T. WEST, J.P.

HORTICULTURISTS generally, and Dahlia specialists in particular, will be pleased to learn that Councillor J. T. West, of Brentwood, has been appointed a Justice of the Peace. Mr. West has raised many fine Dahlias. He has been prime mover in the increasing allotments at Brentwood, where he has been a member of the Urban District Council for twenty years.

MEETING OF THE SEED TRADE AT PRESTED HALL.

A MEETING of the seed trade was held at Prested Hall, Kelvedon, Essex, on the 28th ult. Amongst those present were Mr. Prothero, Minister of Agriculture, Sir T. McKenzie, K.C.M.G., High Commissioner for New Zealand, the Hon. Edward Strutt, Lawrence Weaver, Esq., C.B.E., Director of Supplies, Dr. Stapledon (Government Seed Testing Station), and Professor Biffen.

Mr. J. E. N. Sherwood, Managing Partner of Messrs. Hurst and Son, proposed the health of the President of the Board of Agriculture, the

Right Hon. R. E. Prothero, M.P. Mr. Sherwood said Orders had been formulated which may or may not have been advantageous to the seed trade. The Seed-Testing Order, he believed, was a very good Order, and he was sure it would benefit the seed trade in the long run; it applied more to Clover and grasses than to the vegetable and horticultural departments. The allotment movement very closely concerned the seed trade, and it was a very vexed problem as to how the allotment holders were to be supplied. The various societies were banding themselves together as Associations throughout the country; and it was in their interests and in that of the trade to find a satisfactory solution of the difficulty. There was also the question of the price of seeds.

Mr. Prothero said he was grateful to seedsmen for the loyal way in which they had acted up to not only the letter, but the spirit of the Seed-Testing Order. Many at first thought it an arbitrary Order, but he was glad to hear from the leading firms that they recognise it as an Order framed in the best interests of the nation and the seed trade generally. The shortage of seed of the most important kinds had never become really acute. The supply had been well maintained, and this in spite of the fact that we have suffered great losses from submarines, imports of foreign seeds being delayed or interrupted, and the harvest of 1917 at home little short of disastrous. Owing to the foresight and organisation of the trade, the supply had been maintained, and it is an achievement of which the trade may well be proud. A new field was opening up for the seedsman—that of the allotment holder. The Food Production Department had during the past 18 months added over 800,000 holdings to those which already existed. An increased demand for seeds would also be made from other quarters. There was bound to be, as soon as peace was declared, an enormous demand for seeds, not only in the overseas Dominions, but in the Allied countries that are now being devastated by the war, and in the countries of the Central Powers. He hoped that the seed trade was making preparations beforehand for the new demands from these and other sources. Referring to the Plant Breeding Institution at Cambridge, Mr. Prothero stated that the Government proposed to create by voluntary subscriptions an Institute of Agricultural Botany which would take the plants as soon as they were "made" by the Plant-Breeding Institute, and carry them on to the commercial stage. Seedsmen will then be asked to step in and do the distributing side of the business. Seedsmen should be represented on the committee of the Institute. Practical men were needed to indicate to the man of science the directions in which his investigations were most needed, and to prevent waste of time on experiments, which from a practical point of view were comparatively of little use: to turn him—to take an obvious illustration—on to the task of "making" a Potato immune from blight or wart disease. To this Institute the Seed Testing Station would be removed. Toward the founding of the Institute their host had contributed the sum of £1,000, and £1,000 had been given by Messrs. Sutton and Sons.

CROPS AND STOCK ON THE HOME FARM.

PLOUGHING GRASS LAND.

MUCH has been written in the daily press against the enforced ploughing of grass land and not much in favour of the practice. Those who do not agree with the principle of increasing the arable area can easily find cases of ill results. They strengthen their argument by instancing cases which, when investigated, prove to have been done in a half-hearted manner. The subject requires much consideration before drastic alterations are made in the methods of carrying on the farm applicable to any particular locality, and local circumstances of soil and situation.

I advocate the ploughing of grass land which does not produce one ton of hay per acre, or I would first ascertain if it were not possible to make such land give a better yield.

Too many have a belief that a grass field should produce heavy crops of hay annually for say thirty years without giving the ground any manure. Such land is better under the plough, and the chances are that it will get better treatment by the same farmer, because he will realise that something must be done to cultivate the ground better or he will lose by the transaction. Grass land that produces adequate supplies of hay and good feed afterwards for cattle, should not be ploughed, but even such pasture can often be improved by a judicious use of suitable fertilisers.

The growing of satisfactory crops of cereals on newly broken up grass land requires much thought and method of manipulation if success is to follow.

I am bold enough to say that success will be assured in the growth of crops if the right methods are adopted, in spite of the prevalence of wireworms and leather jackets, about which we hear so much at the present time.

As the result of ploughing grass land I have had satisfactory crops of the following:—Tartarian Oats on grass eighty years old; autumn-sown Red Standard Wheat on a twelve-year-old Sainfoin ley; April-sown Red Nursery Wheat on grass nine years old; and Potatos on turf over 100 years old.

A mistake commonly made with cereal crops is to plough too early before sowing the corn. Take spring-sown Oats, for example. Many think the grass should be ploughed in the autumn, allowing time for the turf to decay, and thus aid in feeding the cereal plant. This is the greatest mistake, because such procedure encourages wireworms to attack the Oat plant directly growth commences, whereas if ploughing is deferred until sowing time the wireworm, which naturally is harbouring in the turf, ramifies through this, and by that time the Oat plant has had time to start into growth. If accelerated by suitable stimulants the plant quickly gets out of harm's way, which is after the first pair of leaves are fully developed. The manner in which the plant is induced to start into growth is the crux of the whole question. I have treated this subject somewhat fully because the time is fast approaching when the Government may require more grass land to be put under the plough.—*E. Molyneux.*

Obituary.

ALEXANDER PORTER.—We regret to announce that Mr Alex. Porter, market gardener, Davidsons Mains, Edinburgh, died on the 3rd inst. An Ayrshire man, he served in some of the leading gardens in the south of Scotland, including Foodel (Fife) and Drumlanrig. Over twenty years ago he relinquished his post as gardener at Luchie, Haddingtonshire, and started in business as a market gardener, but he never lost his interest in plants generally. He gave special attention to Montbretias and Michaelmas Daisies, on the growing of both of which he read interesting and valuable papers at meetings of the Scottish Horticultural Association.

GARDENING APPOINTMENT.

Mr. F. W. Miles, for the past 4 years Gardener to A. E. CUMBERBATCH, Esq., Ware Park, Ware, Hertfordshire, as Horticultural Instructor to the Y.M.C.A. in connection with their Training Centre for Discharged Soldiers.

ANSWERS TO CORRESPONDENTS.

ANTS IN LAWNS: *N. S.* Ants are troublesome in gardens; they often carry aphides from one plant to another, and when present in large numbers cause great disturbance of the roots of plants by working in the soil, making it light and dry. The damage they do plants is indirect rather than direct, but children and some older folks often suffer considerably from their bites. Boiling water poured into the ant-hills will kill the pests, but the water should be at boiling-point when applied, and in sufficient quantity to reach the ants while still hot. Where the use of boiling water is out of the question a proprietary preparation such as Ballikinrain Ant Destroyer should be used; this may be obtained from seedsmen and horticultural sundriesmen.

DISPOSAL OF SURPLUS PRODUCE FROM ALLOTMENTS: *J. D. B.* The Food Production Department has recently issued a Memorandum on the disposal of surplus produce from allotments. Apply to the Department for a copy of this Memorandum; the address is 72, Victoria Street, Westminster.

GRAPE SPOT: *H. G.* The spotting and shrivelling of the fruits is due to an attack of Grape Spot (Gloeosporium ampelophagum), also known as Grape Rot, or Anthracnose. Dust the affected Grapes and leaves with flowers of sulphur, and after an interval of ten days, give another dusting, but add a small quantity of quicklime to the sulphur. If the disease is not cured continue the applications at similar intervals, but increase the amount of quicklime on each occasion until the sulphur is only slightly in excess of the lime.

HORTICULTURAL TRADE NEWSPAPER: *J. D.* There are several horticultural trade newspapers, but these circulate only among the traders themselves, and great care is taken to prevent these papers from getting into the hands of retailers and amateurs. If you are going into business, write to Messrs. A. and C. Pearson, Lowdham, Notts; Mr. J. S. Brunton, Hortus Printing Works, Burnley; or Mr. T. Want, Hatton House, Great Queen Street, W.C., for particulars regarding the trade papers they publish.

ONION MILDEW: *K. S. H.* The disease from which your Onions are suffering is the common Onion Mildew (Peronospora Schleideniana). This complaint more often attacks spring-sown than autumn-sown crops, but in either case it may be kept in check, if not entirely prevented, by means of frequent applications of lime and sulphur, dusted upon the plants while they are moist with dew. Use one part of lime to two parts of sulphur. Spraying the young Onions with potassium sulphide solution—half an ounce of sulphide dissolved in one gallon of water—is a good preventive measure. In districts where Onion Mildew is a prevalent disease, and especially in gardens where there have been severe attacks, it will be found good practice to provide a new plot for the Onion crop each year.

NAMES OF PLANTS: *W. J. H.* Circaea lutetiana (Enchanter's Nightshade).—*W. J. W.* Fraxinus excelsior var. heterophylla, sometimes known as F. excelsior var. monophylla—the One-leaved Ash.—*B. B.* Lilium Martagon.

WILLOWS FOR COMMERCIAL PURPOSES: *C. F. C.* The Willows most suitable for the position you describe would probably be forms of Salix viminalis and S. triandra. There are numerous forms of each species grown for basket-making, and of the many, those of S. viminalis called Long Skin or Long Skein, and the form of S. triandra known as Stone Rod, should be tried. It is not advisable to plant one kind only, for in the event of the one suffering from any cause and failing to produce a full crop of rods, the other may escape. Each kind must, however, be kept separate. The ground should be well cultivated before planting, and kept clear of weeds afterwards. When planting place the Long Skin variety 20 inches apart each way, and the Stone Rod 18 inches apart each way. You may be able to obtain cuttings of these varieties from Mr. W. P. Ellmore, The Willows, 3, Saxe Coburg Street, Leicester. This grower would also be able to advise as to whether any other varieties would be more suitable than those named for the position in question. The Board of Agriculture and Fisheries publishes a useful pamphlet on the Cultivation of Willows. It can be obtained, price 2d., from the Secretary, Board of Agriculture and Fisheries, 4, Whitehall Place, London, S.W. 1.

CULTIVATION OF CYCLAMENS.

THE florists' Cyclamen may be had in flower from the end of November till late in April, provided that suitable strains are grown and proper methods of cultivation are practised. In well-grown plants the beautiful foliage and long range of distinct colours are much admired, and the plants lend themselves to all purposes of decoration. What could be more beautiful and effective than a tastefully arranged grouping of batches of these plants arranged according to colours, commencing say, with *Salmon Queen, soft salmon-pink; *Princess May, beautiful pink; *Rosy Morn (giganteum var.), delicate rose tinted; *Mont Blanc (giganteum var.), pure white, with large flowers, perhaps the best of all white; Mauve Queen (giganteum var.), a robust grower; *Salmon King, the best of all salmon varieties, very free flowering, with large flowers and beautiful foliage; Surrey (giganteum var.), a lovely deep pink, with claret base; *Brilliant (new), giganteum variety, with fiery-crimson flowers of great size; Dame Blanch (giganteum var.), pure white, with exceedingly large, broad petals; Duke of Connaught, purplish-crimson, an excellent grower, and free-flowering variety (a general favourite in America); Duke of Fife (giganteum var.), flowers very large and of rich rose colour; Queen Mary (new), large salmon pink flowers, very free flowering, with beautifully marked foliage, very distinct; picturatum (giganteum var.), the first variety to receive an Award of Merit, although raised over 40 years, and still a popular variety, free flowering, and having beautiful light rose tinted flowers, with claret base; Excelsior (giganteum var.), white with purple base, exceedingly large flower; and grandiflora alba giganteum, a strong grower and perhaps the largest white variety grown.

The variety *Mrs. L. M. Groves is certainly one of the finest yet raised, and is a beautiful and well built flower, of a rich gorgeous salmon-scarlet; its free flowering qualities are remarkable. It is undesirable to convert this variety into a perpetual flowerer, therefore it is forced into its well-earned rest (in the case of growing old corms). The rich, warm scarlet tone highly recommends it for table decoration. The flowers are exceedingly large, and produced from self supporting flower-stems, surrounded with a beautifully marked and distinct foliage.

*St. George's Salmon, the well-known silver leaved variety, was first introduced to the public by Messrs. Sutton and Sons, in 1915. Since then this variety has undergone great improvement both in foliage and quality of flower. The leaves are most beautiful and ornamental in themselves and an additional attraction to the beautiful salmon-coloured flowers. The variety when first introduced was found somewhat difficult to cultivate, and comparatively few gardeners succeeded with it. The strain is so much improved that the plants are almost as vigorous as the giganteum varieties, and the leaves are distinctly marked with silver inlaid with an "Ivy leaf" of dark sap green in the centre and surrounded with silver steel colour, so perfect in appearance that it might have been laid on by the brush of an artist. In addition to St. George's Salmon, a novelty has been raised with a very vivid crimson flower, a good decomposition, having the magnificent decorative foliage of St. George's Salmon. The variety received the R.H.S. Award of Merit under the name of "Crimson St. George's," and in due course will be introduced to the Cyclamen enthusiast.

The first essential before sowing Cyclamen seed is to select a superior strain; no matter how zealous the grower may be, he will never cultivate to perfection an inferior strain. The numerous named varieties are the offspring of Cyclamen latifolium, introduced from Persia in 1731. England was the first country to take up seriously the cultivation of the Cyclamen, but no improvement in strain is recorded until about 60 years ago. Previous to the war Germany made a great effort to monopolise the Cyclamen seed trade of this country, and German seedsmen have distributed throughout the country a strain of inferior quality. The year previous to the war they introduced a so-called new Cyclamen, also one dissected variety, which, on trials under most adverse conditions, proved worthless. Her scheme was to flood the market with cheap seed, and thereby handicap the specialists of the country who aim at the development of perfection in the Cyclamen.

SEED SOWING.

The best time to sow the seed is from July till the end of August. It is completely wrong to sow in spring, as if the sowing is delayed till then there is a loss of valuable time. The method of drying off the corms in summer was once thought a good plan, but this has now been abandoned by all good cultivators. The question of sowing the seed is most important, and if the grower is to succeed he must observe thoroughness from the commencement. Cyclamen seeds cannot be forced into germination if they refuse to move at my pace but their own. Unsuccessful growers may trace their mistakes to one or other of the following stages: Sowing, pricking off, first potting, final potting, watering, ventilation, or feeding. Immediately the Cyclamen is checked in its development disaster follows, and whilst many plants may recover owing to the attention of the cultivator, others will die. It sometimes happens that the seed germinate in the seed pans, and a few fail to germinate, or they germinate very poorly, only 10 or 20 per cent., and the conclusion is that the seed supplied was either bad or "old." This may be true in some cases, but it may be interesting to many of the readers of the *Gardeners' Chronicle* to learn that the old seeds in the case of Cyclamens germinate more satisfactorily than new. The Cyclamen specialist always prefers to sow seed two or three years old; indeed, it has been proved that Cyclamen seed seven years old, if properly stored, will germinate satisfactorily.

To have Cyclamens in flower during November the seed should be sown early in July. Proceed by preparing a compost of 3 parts fibrous loam and one part decayed Oak leaves. If the loam is light in nature, and contains a good percentage of sand, do not make the compost too light by adding more sand; the grower's discretion must be used as regards the nature of the loam. The best quality loam for Cyclamens is to be obtained from the famous Wealden Heath, Surrey. The Oak leaves should be gathered during the winter prior for use. Gather the leaves as they freshly fall from the trees, place them in bags or boxes, and dry them over the [illegible]. When in a fit condition to use [illegible] crumble in the hand when [illegible]. Pass both soil and leaves through a [illegible] mix them thoroughly together. Use [illegible] pans, clean and well crocked and [illegible] some rough material to prevent the fine soil choking the drainage. Fill the pans [illegible] moist and press it moderately firm. When large quantities of Cyclamens are grown [illegible] be equally distributed over the [illegible] but where a less quantity is required [illegible] to be placed one inch apart each way. Cover the seeds into the surface, and cover them with the same compost about ¼ inch deep. It is a great mistake to place the pans on shelves in a heated house, for disaster is sure to follow. This reminds me of an unsuccessful grower who placed the seed pans on the shelf of a Cucumber house, naturally the seeds refused to germinate, and a complaint was made to the seedsman, who consulted his grower, and was satisfied that the seeds were in splendid condition. The remaining seeds having been handed over to the grower were immediately sown. Later on all the seed germinated, and when large enough to handle the seedlings were forwarded to the purchaser, who, perhaps, was unaware that the seedlings were the result of the returned seeds. After the seeds have been sown, place the pans on a coal ash or gravel bottom in an unheated greenhouse or frame, cover them with sheets of glass, and over them place paper to exclude the light. Never allow the pans of seed to become dry, and when giving water this must be done through a very fine rose. Cyclamens dislike hard water; it is therefore a very important factor to have a good supply of soft rainwater. *J. H. Forsyth.*

(To be concluded.)

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM GATTON PRINCESS.

A NOTE on this very remarkable hybrid, raised in the gardens of Sir Jeremiah Colman, Bart., Gatton Park, Surrey (for Mr. J. Collier) between O. Queen of Gatton (triumphans × percultum) and O. eximium (ardentissimum × crispum), was published in *Gard. Chron.*, June 17, p. 242. The chief character of variation in plants of the same batch was referred to, one set approaching O. triumphans in the main features, with O. crispum for a base, the diffused arrangement of the colours in the other set, and the crest of the lip, being easily traceable to O. Harrysianum. Those three species give the dominant characters, although the white O. Percultum appeared three times in the lineage. Sir Jeremiah Colman kindly sends six more blooms taken from a batch of twenty-five now in flower, no two flowers are alike, but all are good.

The six may be divided into two sets of three, the variety with light ground colour (see upper flower, fig. 8) represents the class in which the white of O. crispum predominates with a shade of yellow towards the margin derived from O. triumphans, which also shows in the two bladed crest of the lip and the dark chestnut red blotch in front of it. The other two forms of this class are marked in the same manner, but with a different arrangement of the blotches, which in all three are shades of reddish-purple.

The flowers of the other set (see lower bloom in fig. 8) have diffused colour, and show more of the characters of O. Harrysianum, especially in the fimbriated character of the crest.

* The varieties marked thus * have received the R.H.S. Award of Merit.

The variety illustrated is the lightest in colour of the three, the tint being light claret-purple with lilac markings and tips to the sepals and petals, the lip being blotched with dark claret-red. The next darker form is dark claret-red with smaller lilac markings on the segments, and the third, while showing a few white transverse markings on the sepals and petals, has colouring of a still darker hue.

ODONTOGLOSSUM GATTON EMPEROR

SIR JEREMIAH COLMAN, in his letter, remarks: "But if Gatton Princess has proved variable, Gatton Emperor (Lambeauianum × hybrid unrecorded) has proved still more so. I am sending you four flowers of plants of this cross all arising out of the same seed-pod. You will probably remember the one which gained an Award of Merit (R.H.S., Feb. 12, 1918), which had a self purple ground, hence the name Purple Emperor, so they vary from almost wholly pure white

FIG. 5. VARIATION IN HYBRID ODONTOGLOSSUMS OF THE SAME PARENTAGE. (O. QUEEN OF GATTON × O. EXIMIUM.)

to a deep purple, and one or two are brown. Unlike Gatton Princess, there have been some really bad ones amongst them; in fact, there have been all sorts of shapes, sizes and colours." The flowers sent include a large, pure white bloom with four violet spots and some marginal markings around the crest. This may be likened to a fine, enlarged O. Pescatorei, and can only be derived from the O. Pescatorei in O. Rolfeae (one of the parents of O. Lambeauianum), and suggests that that species may also be in the unknown hybrid used. Another resembles O. crispum purpurascens (illustrated in *Gard. Chron.*, April 13, 1901, p. 233), with its dense spotting on pale lilac ground. The other two are reddish-purple with white margins and tip.

These examples show the extraordinary complication which has arisen in cross-breeding Orchids and the impossibility of identification by means of a single flower, as blooms of quite dissimilar crosses frequently approach each other. In studying them the reasonable method is to work out the distinct species originally used in their production, which, as in the cases now remarked on, can be well traced.

TREES AND SHRUBS.

NEW CHINESE LILACS.

MANY of the Lilacs discovered by Mr. E. H. Wilson and other travellers in the recent explorations of western and northern China are now so well established in the Arnold Arboretum and in a few other American gardens that it is possible to form an opinion of their value. Observations of the living plants show that too many species were made when botanists had for diagnostic purposes only the dried specimens sent home from China. According to the *Bulletin of Popular Information*, Vol. IV., No. 7, issued by the Arnold Arboretum, now that most of these plants have flowered in the Arboretum and have been again studied, it appears that Syringa Wilsonii and S. Dielsiana are the same as S. tomentella; that S. Sargentiana is a variety of S. Komarowii with a pubescent calyx; that S. tetanoloba is S. Sweginzowii (see fig. 11), and that S. Rehderiana is probably only a pubescent form of S. tomentella. S. Komarowii Sargentiana is not in the Arboretum collection and probably has not been introduced. S. Rehderiana, S. Potaninii and S. verrucosa are still unknown in gardens. As a garden plant the handsomest of the new Chinese Lilacs is Syringa reflexa, which Wilson discovered in western Hupeh. This is a tall, broad shrub with leaves resembling in size and shape those of S. villosa. The flowers have long, slender corolla-tubes and are borne in long, wide-branched, open, drooping clusters; the flower-buds are red, but as the flowers open the corolla becomes dark rose colour except the inner surface of the lobes, which is white. The wide, drooping clusters, and the contrast in the colours of inner surface of the corolla-lobes and its tube, make S. reflexa one of the handsomest and most interesting of the new Chinese Lilacs.

Next in merit probably as an ornamental plant is Syringa Sweginzowii. This, too, is a tall shrub, but the branches are not so stout as those of S. reflexa, and the leaves are narrower, pointed at the ends and pale on the lower surface. The flowers are produced in broad, erect clusters, are pale rose colour and half an inch long. The flower-buds are of a peculiar brownish-green colour, and as the flowers open gradually from the bottom to the top of the cluster the contrast between the open flowers below and the closed buds above give this plant a peculiar appearance during the week or ten days the flowers are opening. This Lilac was first made known through plants raised in the Arboretum of Max von Sivers at Riga, in Russia, from seeds sent from some place in Mongolia or Northern China, the name of which is not recorded. Later it was found by Mr. E. H. Wilson in Western China, but the plants growing in the Arboretum were obtained from the nursery of Regel and Kesselring in Petrograd. S. Komarowii has leaves which resemble those of S. reflexa, but the flowers are produced in short, compact, nearly cylindrical clusters nodding on long stems. The flower-buds are bright red and very conspicuous, and the open flowers are deep rose colour. This Lilac sometimes blooms profusely when still a small bush.

Syringa tomentella promises to grow taller than the other new Chinese Lilacs, for some of the plants in the Arboretum are now nearly 10 feet high. The leaves resemble those of S. villosa, and the flowers are pale rose colour or white, and are borne in narrow, erect clusters. None of the Arboretum plants has produced many flowers, and S. tomentella promises to be one of the least desirable of the new Lilacs as a garden plant. Syringa Julianae flowers earlier than most of the new Chinese Lilacs. It forms a compact, low shrub nearly as broad as high, and for several years the specimen in the Arnold Arboretum has covered itself with short clusters of rose-coloured and white, fragrant flowers. Related to the Chinese S. pubescens, it blooms much later than that and other related species, and is an excellent addition to the list of Lilacs which can be grown in gardens.

Syringa Wolfii, which has dark purple flowers in short, compact clusters, is another good garden plant in America. This species, too, was first cultivated by Von Sivers at Riga, who obtained it from some place in Northern China which is not known. The other new Chinese Lilacs in the Arboretum, S. Meyri, S. microphylla, S. pinnatifolia and S. yunnanensis, have comparatively little decorative value, and are curiosities rather than good garden plants.

FRUITING OF FICUS RADICANS VARIEGATA.

CLIMBING species of Ficus, grown for the beauty of their foliage, are seldom seen in fruit, because they are mostly grown as small plants in pots, instead of being planted out and allowed to attain the adult stage, when they develop arborescent branches, with a different type of foliage. The fruiting form of Ficus radicans variegata was shown at a recent meeting of the Royal Horticultural Society by Mr. L. R. Russell. Although grown in a pot of moderate dimensions, the branches were stout and self-supporting, not pendent. The leaves were 3-4½ inches long, 1½-2½ inches broad, and leathery, but not rugose like the corresponding form of F. stipulata. The fruits were larger than Peas, oblate, and green or variegated, just as Acer Negundo variegatum habitually is. The plant had been fruiting for three or four months before it was shown. *J. F.*

THE ROSARY

SOME NEW ROSES.

Of the dozen or so new Roses which found their way into my garden for the first time last autumn, one of the most pleasing has been Lamia (see fig. 91), which received a Gold Medal at the recent N.R.S. Show at Regent's Park, where it was particularly well shown by Mr. Easlea, the raiser. The variety has a vigorous habit of growth, branching and growing well as a cutback. The colour of the flower first opened somewhat resembles that of Lady Hillingdon, but the tone deepens as the flower develops, and it comes to look like a deeper Mrs. A. R. Waddell; the colour, that we may be described as a deep orange-yellow. The flower is essentially of the decorative type, and [illegible] about the same degree of fulness as Mrs. A. R. Waddell. It is, however, very shapely when young, and [illegible] and [illegible] in the garden is [illegible] brown flower stems, [illegible] foliage, [illegible] seem to set off the colour of the flower by the contrast of orange against brown. The thinness and consequent [illegible] of the blooms is its chief defect, for like Lady Pirrie and Roses of that type, when [illegible] the flower goes to pieces. Plants [illegible] over, so that a [illegible] garden, could do well to give the new variety a trial.

Gorgeous, brought out by Messrs. Hugh Dickson, Ltd., two years ago, I [illegible] curiosity in its way. I have only a single plant but it has grown well and produced many flowers of all sorts of colouring. Some have been nearly yellow, others nearly pure pink, and others intermediate shades. The bloom is well shaped, usually of the Mme. Leon Pain build of flower, but often larger and more [illegible] blooms are of sufficient merit for the front row of the exhibition box. The growth seems vigorous and good, and the plant may in the bedding [illegible] prove useful for bedding purposes. Down to the present it has seemed free from disease, but it is the autumn that puts Roses to the test in this respect. If it is as successful through the autumn as it has been in early summer, it should obtain a fair place as a bedding variety.

The new variety Queen Mary has bedded particularly well this summer, and, when at its best it is a Rose of much charm. The colour is a curious mixture of pink and cream which is very delicate in the freshly opened flower. It is true that the growth is not remarkable for vigour. The statement made by a critic at the recent Rose show that the plant will not grow as perhaps exaggerated, but the Rose is not as strong as either of those above mentioned, and, moreover, it is not very good in wet weather. The result has been that my plants of it have in past years been somewhat neglected, but this season has suited them well, and they have produced a few very pleasing flowers, the combination of pale lemon-orange and pink in the flower being very attractive. It is purely a decorative variety, and one would not expect to see it in an exhibition collection.

Paul's Lemon Pillar was particularly good in the early part of this summer. It is a Rose of great merit, for it has the attribute that each flower is beautifully formed and most attractive. Now that we obtain so many new varieties annually this attribute is becoming increasingly important. Garden room is precious, therefore space can no longer be provided for plants of those varieties which only occasionally produce a perfect flower. *White Rose.*

ON INCREASED FOOD PRODUCTION.

TRIAL OF EARLY POTATOS.

I HAVE made a trial of twelve varieties of early Potatos this season for the purpose of discovering the best for our dry, sandy soil. The seed tubers were all planted on March 25, and under precisely the same conditions in land that had previously been cropped with Onions and early Peas. After having been trenched and heavily manured the ground received a dressing of soot and a sprinkling of manure from an old hotbed. The results are as follows: Myatt's Improved Ashcroft, a poor crop, small haulm; Lady Lonsdale, poor crop, moderate haulm; Duke of York, fair crop, good sort; Express, poor crop, small haulm, weak; Epicure, good crop, fairly strong haulm; Early Rose, good crop, haulm strong; Snowdrop, fair crop, haulm strong; Sharpe's Victor, good crop, haulm strong; Eclipse, medium crop, small haulm; King George, good crop, haulm strong; Midlothian Early, fair crop, good tubers, haulm strong.

The old Early Rose was by far the best and gave the largest tubers and heaviest crop. Snowdrop was an excellent second, and Duke of York a good third. I should add that a sample of all the varieties was dug and the Rose, with the above results. Of the other varieties grown here Arran Chief is very prominent and is the strongest and most vigorous of late sorts. King Edward is not so vigorous as last year. Up-to-Date is very strong and healthy. A large plot of Snowdrop, in a field, [illegible] great promise, as also does Epicure. The soil in those gardens is extremely light, resting on the Bargate rock, which is 5 to 10 feet below the surface. *W. A. Cook, Abbot's Wood Gardens, Godalming, Surrey.*

CLIMBING HARICOT BEANS.

I HAVE, under certain conditions, Climbing Haricot Beans can be ripened for winter use. I never [illegible] any doubt, for I observed the development of it to which Mr. Bartlett alludes [illegible]. At the same time there is many [illegible] have experienced, with bad seed. I [illegible] question to an expert, and his opinion [illegible] was most likely due to the method of drying adopted. However, [illegible] seedlings under glass I have [illegible] but could probably have had

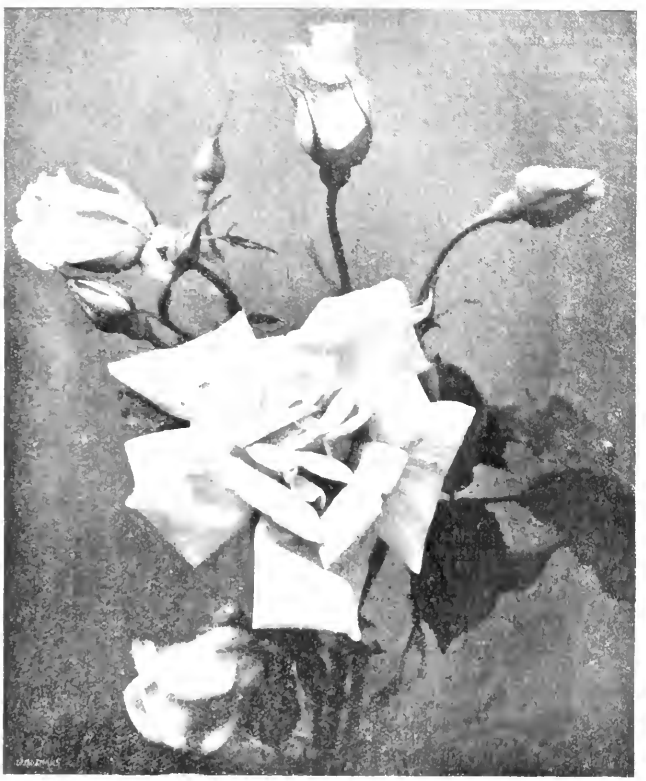

FIG. 91.—ROSE LAMIA (GOLD MEDAL, GRAGE YELLOW).

[illegible] ground had not been mulched. My soil is of poor quality and dries quickly, so there will be no struggle for supremacy between the two vegetables. It seems easy to say what can be done with a piece of ground before it is seen, but 4 to 6 inches of soil overlying solid gravel, and as dry as dust during the middle of March, is liable to create misgiving as to its capabilities.

I still think I did right in giving Potatos the first place for the first year of grass land, and so far they have justified my decision. Most of the ground presents a dark green appearance owing to the presence of Potatos as the principal crop on the 3 acres put under cultivation. The influence of weather on crops is greater than that of manure, which has had no effect for two months owing to lack of moisture in the soil. My third sowing of Climbing Haricot Beans, made 14 days later than the last, promises to

outstrip the first because the seeds were planted in deeper soil, containing more humus. All have an equal share of light and warmth. Plants of the third sowing have rather less air, but the fourth requisite to the vigorous growth of plants—moisture—has been deficient. *J. F.*

LEEKS.

OWING to the prolonged drought the Onion crop this season is certain to be light, and in order to make up for the deficiency increased space should be allotted to Leeks. Generally the seed has been of high germinating quality, so there should be ample seedlings available. Like practically all plants, the Leek pays for good cultivation, although for ordinary purposes the methods of the grower for exhibition are not necessary. On light soils it pays to make trenches as for Celery, though not so deep nor so wide. Trenches to take two rows of plants will be found the most convenient for working, though some of the older experts often recommended a larger size. John Abercrombie thought trenches to accommodate six rows of plants at 6 inches apart the best, but this width is rather unwieldy, and the plants would become too crowded. Better results are to be obtained by allowing 9 inches from plant to plant. If well-decayed manure of any sort is available a layer at the bottom of the trenches will give good results. On stiffer lands there is much to be said in favour of the method of dibbling deep holes on the flat and dropping a plant into each hole. One watering will ensure a sufficient covering of soil over the roots, and the stems will become blanched as they grow, but care must be exercised to make the holes sufficiently deep; 9 inches should be the minimum depth. Where worms abound the leaves of the seedling Leeks should be trimmed before they are planted, otherwise the worms will drag them into the ground. On rich soils Leeks grow so robustly that they should be allowed 12 inches from plant to plant. The general impression amongst writers seems to be that Leeks are much more popular in the North than amongst gardeners of the southern counties. Whatever may have been the case in the past this is scarcely now correct. Very large areas of Leeks are grown by market gardeners in most of the London suburbs, and it is rare to find southern allotments or cottage gardens without due proportions of Leeks in their season. In Cornwall the Leek has long been one of the most important vegetables with the cottager, who, realising the value of high feeding of the plants, usually grows them exceedingly well. *A. C. Bartlett.*

CARROTS

To make certain of a good supply of Carrots for winter and spring, a sowing should be made of a stump-rooted variety. A good dressing of soot should be worked into the soil, and the seed sown thinly in drills 9 inches apart. If the soil is fairly moist at the time of sowing it is not long before germination takes place; a free use of the Dutch hoe helps the seedlings to make headway. Thinning should be done when the seedlings are large enough to handle, dusting the foliage with soot to ward off attacks of the Carrot fly. Many growers prefer to leave Carrots sown this month unthinned, but should a period of dry weather occur the roots will not grow to a serviceable size before the growing season has finished. *C. Davis, Holy Wells Park Gardens, Ipswich.*

THE ROYAL HORTICULTURAL SOCIETY AND FOOD PRODUCTION.

THE Society is continuing the good work referred to in these columns on previous occasions. During Whitsuntide the special exhibition of models, insect and other pests, tools, Haricot Beans, and literature, was displayed at the Food Control Bureau at Bournemouth, where Lord Grimthorpe, the President of the Society, opened the proceedings. There was an average attendance of about 700 visitors per day, and Mr. C. H. Curtis, who was in charge, answered questions and gave short talks that were of special interest to allotment holders. From Bournemouth the exhibition was conveyed to Southall, Middlesex, where the allotment movement has developed very extensively. Here the attendance was about 300 per day. Lady Rhondda opened the proceedings, and spent some considerable time inspecting the Society's exhibit. From Southall the exhibition was taken to Ludlow, and later to Smethwick, Mr. W. H. Divers having charge of the arrangements. The next centres visited were Torquay and London (Selfridge's).

PLANT NOTES.

RHODOSTACHYS ANDINA.

RHODOSTACHYS ANDINA is an ornamental Bromeliad, whether grown indoors as a greenhouse plant or out-of-doors as a tender plant for a warm corner. In the Cambridge Botanic Garden it does well under both methods of

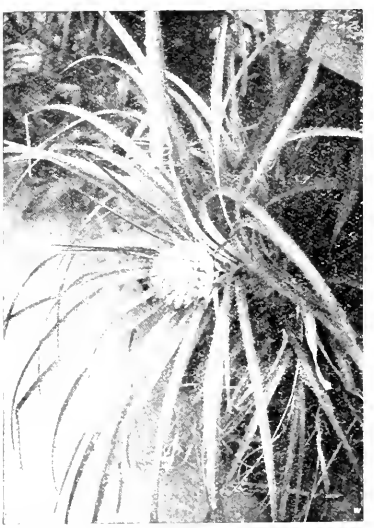

FIG. 10.—RHODOSTACHYS ANDINA FLOWERING IN THE SUCCULENT HOUSE, BOTANIC GARDEN, CAMBRIDGE.

treatment, but specimens out-of-doors with many crowns do not require to flower freely. Indoors the plant has flowered on various occasions.

The specimen illustrated in fig. 10 is growing under the bench of the central stage of the Succulent House. In this position it does perfectly well, and it is one of the numerous plants that can be grown under a stage, thus saving the space above. The habit of the plant is well shown in the illustration. The leaves have a silvery appearance, becoming glabrous down the upper surface, while remaining white-lepidote on the underside. They are armed with very sharp spines. The inflorescence consists of a dense globose head, about 3 inches in diameter; the outer bracts are spine-margined and slightly tinged with red, the calyx segments lanceolate and white, the petals bright pink and about an inch long. The stamens exceed the petals, and have bright yellow anthers. The plant is Ruckia Ellemetii of Regel's *Garten Flora*. In the same conditions, both in and out-of-doors, R. litoralis and R. pitcairniaefolia succeed very well. All the species are native of Chile. *R. Irwin Lynch.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey

CABBAGES.—The most suitable time for making the earliest sowing of Cabbage varies in different localities, but it should be made between this date and August 10. Harbinger is possibly the best sort to sow first, followed by such varieties as Ellam's Early, Flower of Spring, and Early Offenham. Another excellent Cabbage is Emperor; the heads of this variety quickly turn in and are of excellent quality. Where large quantities are grown it is well to make three sowings at intervals of ten days. Sow the seed thinly in rows made 9 to 12 inches apart. Where birds are troublesome protect the seeds with nets and shade the beds with green boughs until the plants are well through the soil, but afterwards gradually expose them fully to obtain sturdy specimens.

TOMATOS.—If a regular supply of Tomatos is needed during the winter, the plants should be ready for transference to their fruiting-pots by the end of August. Late-raised plants grow weakly, and in any case the fruits of such plants fail to set freely during the late autumn and winter. Few varieties equal a good type of Winter Beauty, which is of moderately vigorous growth, flowers freely, and sets its fruits well. Grow the plants on in a light position near the roof-glass.

CUCUMBERS.—The end of July is a suitable time for sowing Cucumber seeds to raise plants for fruiting up to Christmas. Use a light compost and grow the plants in a warm house, although fire-heat is not needed for this crop until September. Grow sturdy plants, and give the roots plenty of pot-room to keep them steadily progressing until a pit is ready in which to plant them; where the pit has been occupied by Melons it should receive a thorough scrubbing and cleansing.

SPINACH.—Make further sowings of Round and Prickly Spinach in drills drawn 18 inches apart on ground which has been cleared of early Potatos. Many of the plants will give a supply of leaves through the autumn, and some will stand the winter. Further larger sowings should be made at short intervals.

LETTUCES AND ENDIVE.—Continue to transplant seedlings of these salads, allowing the plants a distance of 1 foot apart each way. Make further sowings of All-the-Year-Round and Hicks' Hardy Lettuces to furnish plants for cutting during the autumn and winter. Further sowings of Batavian Endive should be made and plants from earlier sowings transferred to cold frames as required.

HERBS.—Most kinds of herbs are ready for drying. The shoots should be cut when in flower and dried gradually by spreading them out in a cool, shady place. They should be tied in bunches afterwards and hung in a similar position, where they will be free from dust and dirt.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

SUMMER PRUNING.—Summer pruning needs to be done with considerable caution, or it will result in autumnal growth that will defeat the object in view. Every variety and its peculiarity must be understood. As an instance, Waltham Abbey Seedling Apple is disposed to form fruit-buds at the terminals of the current season's growth. It is simply waste of time to cut back the wood each summer and have no good results. In such a case, when summer pruning was forgone, and extension of growth allowed, fruit-buds were formed and good crops resulted. Take note now of all fruit trees growing too luxuriantly, and mark these for root-pruning in the autumn. What applies to

some Apples and to Pears on a free stock also applies to Plums; the summer pruning of the Plum is often carried to an excess that is not justified. On light or on shallow soils the beneficial result of summer pruning may be more apparent than on heavy ones. The removal of weakly wood should first receive attention and then the growths which cannot be considered important, but do not cut away all useless or superfluous growths at one and the same time. If any system of pruning adopted in the past has not been productive of good results, try another system. Pendulous growths, if encouraged, often prove fertile.

WATERING WALL FRUIT TREES.—Providing wall-fruit trees with moisture is an important item of work at this season, especially where good crops of fruit are being ripened. It will pay to mulch the border close up to the wall when the crops are heavy, for when the border slopes away too freely the soil frequently cracks. Clear water will suffice, unless it is seen that the growth needs some stimulant. In conjunction with watering in hot weather a free use of the syringe or garden engine, towards the evening, will be beneficial. Bear in mind, where syringing is practised, that there is now one hour's difference in the time, and what could be done at 4 o'clock cannot now be attended to until 5 o'clock. Keep a sharp watch for insect pests, and do all that is possible to exterminate them in good time.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

SMILAX.—If a suitable place is available in which to cultivate this plant, a good batch should be grown annually. Smilax is especially valuable for decorative purposes during the winter. The back wall of a late vinery is an ideal place for growing this plant, and it will grow satisfactorily in fruit houses. The plants may either be set out in a narrow border or grown in boxes. See that ample drainage is provided, and do not use a very rich compost. Strands of fine green twine may be fixed the whole length of the wall on which to train the long shoots. When in active growth constant attention must be paid to training the young growths, or they will quickly become hopelessly entangled.

EUPHORBIA PULCHERRIMA (POINSETTIA).—Any plants of Poinsettia still to be repotted should be attended to forthwith. If tall plants are desired they should be grown in a warm, moist atmosphere for the next few weeks, and afterwards accustomed to cooler conditions. Plants growing in cool houses or frames should not be exposed to cold draughts. Poinsettias may be grown in cold frames if great care is exercised in admitting air.

EUPHORBIA JACQUINIAEFLORA. For ordinary use this plant is best grown singly in 5-inch pots, but large specimens may require pots 8 or 10 inches in diameter. Their cultural requirements are similar to those recommended for Poinsettia, except they need a fairly high temperature throughout their growing season.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

EPIDENDRUM PRISMATOCARPUM.—This species may need attention at the roots when it has passed out of flower. The most suitable receptacles are deep pans. Specimens that are pot-bound, and, having grown over the sides, are bare in the centres, should be turned out of the pans, for the purpose of removing most of the back pseudo-bulbs, leaving only two or three behind each lead. They should then be repotted, placing them so that the growths point to the centre. Those that have sufficient root space for another season's growth, and are otherwise in good condition, should have some of the old material removed from the surface, and be given a top-dressing. After repotting or top-dressing, give water with great care, and never allow moisture to settle in the centre of the new growths, as this will cause decay at the base. When the roots have grown well into the new compost, afford water liberally until the pseudo-bulbs have completed their growth. This species grows well in the lightest and coolest part of the Cattleya house.

EPIDENDRUM BICORNUTUM (SYN. DIACRIUM BICORNUTUM) AND HYBRIDS.—These plants are difficult to cultivate well for many years in succession. At the present time, just before the new growths develop roots from their bases, they should, if necessary, be repotted. Shallow pans form the most suitable receptacles, and these should be well drained. During the growing season, liberal supplies of water are needed, but later, when the pseudo-bulbs are fully developed, the supply should be gradually diminished, and, during their resting season, only a very small amount will be required. The plants grow best if suspended or staged near the roof-glass in the warmest Orchid house, or in an ordinary plant stove.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to Mrs. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

MELONS IN FRAMES.—The very cold nights experienced during the past fortnight may have retarded the growth of Melons in frames, but it advantage is taken of the present bright weather, by syringing the plants lightly and closing the lights early in the afternoon, no harm will result. From leading growths to within the back and front of the frame, two each way are sufficient, and pinch out the tips when they have nearly reached the sides. These leaders will produce laterals in abundance, most of which will give fruit, but the essential point is to keep these laterals thinned so as to admit light and air to those retained. Pollinate the flowers daily, as it is very important to secure a quick set at or about the same time, or only the most forward fruits will swell. Retain three or four of the most promising and best situated fruits, as these will be quite enough for one plant. The fruits should be kept off the soil by pieces of board or tiles to keep them from the soil. When it is necessary, tepid water should be given in the forenoon, but avoid wetting the "collars" of the plants. Warm, diluted liquid manure, light sprinklings of concentrated fertilisers or top-dressings of turf and manure, in equal proportions, should be afforded the roots when the fruits are swelling. Pinch out any fresh growths to prevent overcrowding, syringe the foliage freely and close the frames early.

CUCUMBERS IN FRAMES. The important point in growing Cucumbers in pits or frames is to keep the plants well supplied with moisture, but cold, sloppy conditions in the frame are harmful. In bright weather syringe the plants twice daily and close the frames early in the afternoons directly after the final syringing. A mere fraction of ventilation may be allowed to remain on all night during warm, sultry weather, to allow superfluous moisture to escape. Twice weekly all the shoots should be pinched to one leaf beyond the fruit, and any unnecessary growths or fruits removed to admit light and air. As the roots appear above the surface give light top-dressings of loam and decayed manure or leaf-mould. Warm, diluted liquid manure or light sprinklings of concentrated fertilisers are excellent stimulants for plants carrying good crops. Young frames must still be utilised to provide a successional supply.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

ENGLISH IRISES.—It is, perhaps, not generally known that English Irises succeed best when the plants are raised from seeds, and where the bulbs are apt to die without any apparent reason it will be found that seedlings, frequently raised, will give excellent results. Instead, therefore, of removing all seed pods after the flowers are over, a few should be reserved for propagation, and the seeds may be sown as soon as they are ripe. The plants are absolutely hardy, and the seeds only need to be sown thinly in the open ground and the seedlings left for two years before transplanting. Even Iris species should be propagated in this way, as colour variations of much interest and sometimes of increased beauty may occur.

PEGGING DAHLIAS.—Perhaps the pegging of Dahlias is very unusual, but I have found it for a long series of years for decorative effect. The shoots need to be pegged down only once, and strong and long pegs are needed to hold them in position. Four shoots are usually ample to form the foundation of a bushy plant, but crowded medium habited varieties are better. Stakes or other means of support are needed. Old plants, as opposed to those produced from seeds or cuttings in spring, are best, but the latter may be managed in this way.

DEUTZIAS.—The pruning of Deutzias is effected by thinning out the older flowering shoots in order to make room for young ones. There is a class, of which D. *scabra* is a type, which produces long, straggling shoots, and once a plant has become rather thick the best method is to cut back a few of the strongest growths, as these will break from below the cut and produce strong, flowering growths to fill the place of those removed. Deutzias, like Roses, do best in highly manured soil, and need to be regularly surface dressed with manure to enable them to flourish.

COMMON SHRUBS.—Long shoots of the coarse-growing common Laurel may be cut well back to ensure that amount of trimness which may not be sacrificed in well-kept gardens. A shrubbery may be quickly overgrown, but pruning can be done at any time when other more important work cannot be performed. Weigela shoots that have flowered should be cut out to allow the young ones to take their place to flower another year.

THE APIARY.

By CHLORIS.

USE OF HONEY. In these days of sugar shortage it may be helpful to many bee-keepers to know how to put honey to the best advantage. In the very earliest days it was the only sweetening matter, and was recognised as a most valuable article of food. It is undoubtedly very nourishing, decidedly wholesome, and is considered to be conducive to good health; in fact, early writers always referred to honey as one of the necessaries of life. Honey contains one of the most important foods, sugar in a most wholesome and easily digestible form. Further, honey has great medicinal properties; by its constant use constipation is easily banished, and, unlike cane sugar, honey does not tend to cause teeth to decay. Only in one instance have I known honey to cause any unpleasant results, and in this instance a person had swellings, as if stung, in several parts of the body, particularly about the face, caused, no doubt, by the formic acid added by the bees to each cell before sealing it to prevent the honey from fermenting. In cases of rheumatism, chronic dyspepsia, and climatic troubles much benefit is said to be derived from its continued use. Honey may be used with great advantage for sweetening wherever sugar has been consumed. Used in tea, coffee and cocoa, it adds a peculiar aroma which cannot be attained by the use of sugar. I fear that those who get accustomed to it in these days will never want to use sugar again. It may be used with great advantage for sweetening cakes, and those made by its addition will keep moist longer than when sugar is utilised. A delicious sandwich in these days of meat shortage may be made as follows: Cut thin bread, butter or margarine lightly, cover with honey, sprinkle with oatmeal which has been boiled in the oven till just brown, press on another thin slice, and cut into fingers. Honey can be kept almost any length of time if it be stored in a warm, dry place, and kept quite air tight. Should it granulate or candy it may be restored to its liquid state by placing the honey jar in warm—not boiling—water, until quite liquid. When boiling water is used the delicate flavour of the honey evaporates. As a valuable food for the aged, and young children, honey has few equals certainly no superiors.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER** 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER, *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS 41, Wellington Street, Covent Garden, London**. *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, JULY 23—
Southampton Royal Hort. Soc. show and Southern Counties Carnation Soc. Ann. Ex. at Southampton (2 days).

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 62.9.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, July 18, 10 a.m.: Bar. 27.9; temp. 69°. Weather—Cloudy.

Agricultural Reconstruction.

The Sub-Committee of the Reconstruction Committee, presided over by Lord Selborne, K.G., P.C., has now issued its report* on the methods of increasing home-grown food supplies in the interests of national security. It will be remembered that the first part of the Report of the Sub-Committee, recommending the breaking up of considerable areas of grass land, formed the basis of the Corn Production Act, and has resulted in the remarkable increase of arable land which the Food Production Department has recently been able to record—an increase which undoubtedly ranks among the great achievements of the war, and reflects great credit both on the Department and on the farming community.

The second part of the report insists on the need for agricultural instruction and research, and advocates—as we think, wisely—the placing of the responsibility for agricultural instruction and research on the Board of Agriculture and public funds, and not on the County Councils, as heretofore.

The report advocates a large provision for small holdings, and takes the view that holdings should be of either owned or tenanted type. Here, again, most people will endorse heartily the conclusion reached by the Sub-Committee, and will be glad to see that, in the opinion of its members, provision should be made for ownership as well as for tenancy.

It would be too much to expect that, with the large problems confronting the Sub-Committee, much attention should have been given specifically to horticulture as distinct from agriculture. But, now that the State has recognised the importance of the horticultural industry, it is to be hoped that this omission will be made good, for surely on all grounds future intensive production is no less worthy of careful consideration than is extensive cultivation. Looked at as the means of food production, as a means of employment, or as a source of wealth, there is evidently a brilliant future before those countries which can develop intensive—that is, horticultural—cultivation scientifically. The pre-war imports of fruit and vegetables were vast, and much of this imported produce might have been raised at home. In view of the importance which the Admiralty attaches to the rôle of the submarine in future wars, it is evident that the State that wishes to survive the attack of the Hun of the future must be in a position not only to defend, but also to fend for itself—in other words, it must be on as large a measure as possible a "self-supplier." Experience has shown that even from the point of view of cost the cheap imports of pre-war times become the ruinously expensive things in war-time—witness the imported Onions of last year. But, needless to say, the cost of the import is secondary to the risk of not getting it, and the food shortage of six months ago ought not to be lightly forgotten, nor the moral which it points lost.

The report deserves full and careful study, for it points the way for a real agricultural reconstruction, and if its principal recommendations are adopted, there should be no need for young and ambitious men to leave this country in order to find a scope for their energies and abilities; they would become home colonists.

* Stationery Office, Cd. 9079.

Forestry and the Problem of Afforestation.

Those who have lately been alarmed at the extent of the tree-felling operations which have been carried out in this country during the war will have been somewhat reassured by the appointment of a Government Committee consisting of Lord Curzon and Mr. G. N. Barnes to look into the whole problem of forestry and re-afforestation in this country. Some idea of the extent of the felling which has been done during the past few years may be gathered from the fact that whereas before the war we imported 90 per cent. of our timber, we shall have imported this year only 500,000 tons, the production in this country having reached the colossal amount of three million tons. This production would not have been possible but for the aid of large numbers of Canadian lumbermen. There are now 100 companies working in England and France, the total number of men engaged in the two countries being nearly 30,000.

Naturally, the production of so vast an amount of timber involves the destruction of a very large number of forests; and the problem of how to replace these forests for the benefit of future generations becomes more and more pressing. In countries where forestry has been understood and practised for years, there is a regular system of afforestation, which consists in the compulsory formation of fresh plantations in place of the timber felled, which provides automatically for the maintenance of the original extent of the woodland. Unfortunately, in this country we have had no such system, except on a few private estates owned by conspicuously enlightened landlords. We trust that the appointment of a committee to go into this matter will result in a constructive programme which will preserve the forests in this country from the fate which overtook so many in mediaeval times.

Nurseries should at once be established in proximity to the areas which are to be planted; thousands of acres of the barren heathlands in Norfolk and Surrey could be brought under arboriculture with the expenditure of very little time and trouble. But the bulk of the suitable land is in Scotland, and most of the money to be expended will probably be sent to that country. It will be regrettable if, as has been suggested, two separate bodies be set up, one for Scotland and one for England; such a scheme would lead to unnecessary overlapping, and probably to delay in administration. Schemes for plantings should be dealt with by a central authority, and should be put in hand as soon as they are ready, whether in one country or in the other. We trust that whatever form the Central Board may take, it will consist of members carefully chosen for their knowledge of forestry and their administrative capacity, and that, above all, the work of afforestation will be begun without further unnecessary delay.

AGRICULTURAL WAGES BOARD AND MINIMUM RATES OF PAY.—Among the misapprehensions which are prevalent, perhaps none is more widespread than the idea that the decisions of the Agricultural Wages Board render illegal the continuance of those old-standing customs under which an employer provides part of his men's remuneration in kind: a cottage free of rent, a supply of milk or Potatos, everything, in a word, that is grouped under the expressive term "allowances," except intoxicants. So far as the Wages Board is concerned, these customs are just as legal as they were before it came into existence. The new fact is that some of these supplies, but not all of them, will count as "wages" towards the minimum rates now being fixed, and the Wages Board has to decide which shall count, and how they shall be reckoned. Decisions on these points cannot be taken in a hurry, for old customs need careful handling, and it is not possible at present to say precisely what may be reckoned as "wages," or how the value is to be ascertained. It has, however, been already decided that an employer may reckon the value of milk and Potatos supplied to his men, and estimate it at the local wholesale prices. Any payment in cash, such as beer-money or cider-money may be counted as part of wages, but if beer or cider are given they must be regarded as additions to the minimum wage. The idea that the farmer must not supply what he may not count indicates a failure to grasp the significance of the word minimum. The Wages Board does not fix wages, but minimum rates.

SYRINGA SWEGINZOWII.—The Lilac illustrated in fig. 11 was originally named Syringa Sweginzowii by KOEHNE and LINGELSHEIM in 1910 the material having been obtained from a private arboretum near Riga. The native country of the plant was not known at the time, but a Lilac almost identical with it had previously been found by Mr. E. H. WILSON in Western China in 1904. There it is said to inhabit ravines at elevations of upwards of 17,000 feet. It must consequently be a very hardy shrub. The plant is described as growing 10 feet or more high, the young shoots being purplish. The leaves are ovate or oval, 2 to 4 inches long and half as wide, dark green, and smooth above, paler green beneath, with hairs on the midrib and veins. The flowers are in panicles up to 10 inches long, fragrant, and open in June. The tube of the corolla is about one-third [illegible] the outside [illegible] Siberian Syringa [illegible] orders, and we [illegible] Lilac [illegible] about [illegible] Burkwood [illegible] Sweginzowii [illegible] Mr. Wilson, Gibbs [illegible] Turner [illegible] named [illegible] Mr. Turner [illegible] The species [illegible] Botanic Garden.

THEFT OF ASPARAGUS TOPS AT EPSOM.—On the night of [illegible] Asparagus beds [illegible] Headley Court [illegible] thieves, thus practically [illegible] Asparagus growth [illegible] frequently sold as Asparagus Fern, but buyers should be satisfied [illegible] otherwise private [illegible] to suffer from the depredations [illegible] take considerable risks at [illegible] tain something for nothing. [illegible] gardener says that if Asparagus [illegible] greatly. "Crowns" cannot be produced and therefore valuable food will be lost in the coming years; this fact [illegible] magistrates when Asparagus thieves are being dealt with.

POST-WAR USE OF GOVERNMENT STORES IN AGRICULTURE AND HORTICULTURE.—A large amount of Government [illegible] will be available for industrial purposes at the conclusion of the war, but unless [illegible] hand, proper distribution will be [illegible] We, therefore, welcome the appointment by the Committee [illegible] Agriculture to consider how such stores may best be utilised in the interests of [illegible] and horticulture, and what method of purchase and distribution should be adopted. The Committee is composed of Earl GREY, Dr. F. KEEBLE, Mr. W. R. HOPKINSON, Mr. DOUGLAS NEWTON, Capt. Sir BEVILLE STANIER, Bt., Major the Hon. E. F. WOOD, Mr. J. W. B. PEASE, Mr. H. STEPHENSON, and Mr. N. WALKER, with Mr. E. G. HAYCRAFT BROWN, 3, Whitehall Place, London, S.W. 1, as Secretary.

UTILITARIAN RABBIT KEEPING.—Rabbit keepers are invited to join the National Utility Rabbit Association, which has for its object the rapid increase of rabbits especially suitable for food. By increasing the supply of rabbits the Association hopes to create subsidiary industries from by-products, such as fur. Lord LAM BOURNE, president of the Association, who assumes this invitation, [illegible] rabbit clubs, rabbit keepers' societies, and similar bodies, should become affiliated to the Association as its province is to act as a centre for the distribution of information, the supply of good stock and registration of pedigree. If funds permit, the Association will undertake experimental work and arrange to give demonstrations. The Food Production Department has agreed to make a grant of £500 towards initial expenses provided the Association receives sufficient support from voluntary subscriptions. Before the war between 2,000 and 3,000 tons of rabbits were imported annually as food, and it is desirable that the country should in future become self-supporting in this connection. Particulars of the Association may be obtained from the Secretary, 124, Victoria Street, Westminster.

MR. J. K. RAMSBOTTOM.—We [illegible] that Mr. J. K. RAMSBOTTOM has accepted an important appointment with Mr. GEO. MONRO, Jun., of Covent Garden, whose large interests [illegible] for the Government. From 80 to 85 per cent. of the Rhubarb produced in Yorkshire will be sent to the jam makers.

YORKSHIRE RHUBARB FOR JAM-MAKING.—A Yorkshire correspondent informs us that the Rhubarb growers of Leeds are just now almost [illegible] as they will be on Peace Day, they [illegible] experienced difficulty in getting their [illegible] to distant markets, hence a third of the [illegible] formerly devoted to the growing of Rhubarb was last autumn added to the area of [illegible] and other farm produce. Now, however, [illegible] of all soft fruit is far below the [illegible] Rhubarb growing has been officially declared to be a work of national importance, and [illegible] has already taken over, at a cost [illegible] between 4,000 and 5,000 tons [illegible] of the season's crop which has [illegible] on a large scale in the open. At [illegible] the picking of Rhubarb and [illegible] is being done

FIG. 11.—SYRINGA SWEGINZOWII: PETALS WHITE, TUBE LILAC ROSE.

[illegible] cultivation at Spalding, and [illegible] Mr. RAMSBOTTOM will conduct [illegible] those directors to which Tulips and Dutch [illegible] Iris bulbs, and will devote [illegible] by experiments to [illegible] cover [illegible] and cultural [illegible] Mr. RAMSBOTTOM has had about two years' experience in the study of Daffodil disease at the Royal Horticultural Society's Garden, Wisley, and our readers will remember that he read a paper on this subject before the Horticultural Club on May 8, 1917. The appointment is interesting as showing the progressive spirit that is abroad in commercial horticulture; at the same time it is a pleasure to state that Mr. RAMSBOTTOM'S investigations with regard to eel worm in Daffodils will continue, and the results will be published in the course of the Royal Horticultural Society.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

AMERICAN BLIGHT.—*Market Grower*, on p. 15, asks for a remedy for this insect. I have used the following specific for many years, and proved it to be effectual. Take 4 ozs. of soft-soap and dissolve in 1 gallon of hot water; when thoroughly mixed add 1 oz. of carbolic acid and stir it well into the solution. Apply the specific to all infested places with a stiff paint brush, working it well into crevices. The workman should be careful not to get the mixture on his skin, also to stir it occasionally if the carbolic acid floats to the surface. *W. H. Divers. F.M.H., Westdean, Hook, near Surbiton.*

—— Here this irrepressible pest, as with *Market Grower*, has been unusually troublesome this season. Even two-year-old trees have been attacked. The trees have been sprayed with a 2-ounce-to-the-gallon solution of Gishurst's Compound, which, in the meantime, has proved effectual. Two operators were engaged in spraying, one of whom did his work so efficiently that only dead aphides were to be found on the conclusion of his labour. The other's operations were of no use whatever, the insects being as evident as ever when he had finished. Spraying, to be a success, requires a man with brains as well as hands to operate, and it is vain to explain and illustrate in the case of the mentally incapable. American Blight has well-marked proclivities, colonising on a few varieties of Apples to the exclusion of others. Dumelow's Seedling (Wellington), Ribston Pippin Grange's Pearmain, King of the Pippins, and Blenheim Pippin are the sorts it seems to prefer here, many other kinds, even this season, being immune from attack. *R. P. Brotherston.*

VEGETABLES (see p. 13).—In respect to Mr. Beckett's remarks on various vegetables, I may say that in a long experience I have found sulphate of ammonia and superphosphate of lime the two best "artificials" for vegetables. The former I always employ with a niggardly hand, and instead of scattering it broadcast, apply it rather close to the stem of the vegetable, one application being sufficient. Some crops may have more than one application of superphosphate, Onions, for instance, but where soot and poultry manure are available it is much better to substitute these for repeated dressings of the other. Onions have been completely destroyed in some of the small gardens in this locality. I have lost a considerable number of plants, probably 2,000 out of 10,000 planted, which is quite an exceptional occurrence. I prefer Leeks to Onions, and of those many thousands are looking well. The late Potatos are the best of the Potato crops here. Early varieties are growing in what for some time has been no better than "dust," and the tubers, consequently, are small. Deep-planted Potatos will be much the best crop this year. Early planting, though some folk say it is bad gardening, is also helpful, and no Potatos could look better than those planted early in March and much deeper than usual. Cauliflowers and Cabbages in this district have suffered to a terrible extent from root-maggot. Even Cauliflowers ready to "flower" have been attacked by the pest, and whole plantings have been destroyed. Nevertheless we have, so far, had an abundant supply of Cauliflowers since early in June, with the promise of plenty for another month or six weeks, after which there will be less to fear for the crop. Beet is a complete failure. *R. P. Brotherston*

THE CAUSE OF THE APPLE FAILURE (see p. 5).—I consider that the failure of the Apple crop is due to persistent cold winds at the time of flowering rather than to the drying of the flowers. I much doubt whether any amount of sunshine would have had such an effect on the flowers as your correspondent suggests, although it might, in conjunction with cold, northerly, drying winds. The cold weather kept bees and other insects at home when the flowers were ready for pollinating. So far as my own trees (Dumelow's Seedling and Lord Suffield) are concerned, I am sure the reason I have suggested is the correct one, for not a bee was to be seen when the trees flowered, and yet they did not crop well last year. *C. N.*

SOCIETIES.

ROYAL HORTICULTURAL.

JULY 16.—Although there was nothing of outstanding merit among novelties at this meeting, there was a good exhibition of general subjects, including a capital display of Carnations. These flowers were shown in classes provided by the National Carnation and Picotee Society, which held its annual competitive exhibition in conjunction with the R.H.S. meeting. The attendance was better than at any meeting hitherto held this year. An exhibit of vegetables, staged by Messrs. BARR AND SONS, was of outstanding merit, and was awarded a Gold Medal.

The Clay Cup, offered for the most fragrant Rose, was not awarded, although Mr. HICKS staged Mrs. Elisha Hicks. Mr WALTER EASLEY sent the fragrant Dr. Grew, and Rev. J. H. PEMBERTON entered Pax for this award.

At the 3 o'clock meeting of Fellows a lecture entitled "Battle-Scarred Wastes" (illustrated by lantern views) was delivered by the Rev. Albert Lee, B.Sc., F.R.G.S.

Floral Committee.

Present: Messrs. H. B. May (in the Chair), John Green, G. Reuthe, John Heal, Sydney Morris, J. W. Moorman, Chas. Dixon, E. F. Hazelden, W. P. Thomson, John Dickson, Chas. E. Pearson, W. G. Baker, R. C. Notcutt, W. J. Bean, J. F. McLeod, W. Howe, J. T. Bennett Poë, George Paul, E. H. Jenkins, R. W. Wallace, H. Cowley, and W. B. Cranfield.

AWARDS OF MERIT.

Campanula Enchantress.—A dainty little hybrid Campanula, obtained by crossing the hybrid C. Norman Grove with C. Waldsteimiana. The growth is tufted, and flowering plants are about 6 or 8 inches high; the growth is very slender, but fairly erect, and forms a pyramid, carrying a host of small, semi-pendent flowers, that are a pretty lavender-blue shade. The plant is quite hardy, and should gain popularity alike for the rock garden and the cold greenhouse. Shown by Messrs. THOS. B. GROVE AND SONS.

Yucca Ellacombei.—A handsome form, producing stately spikes 4 feet tall, laden with pendulous flowers, borne on numerous side branches. The colour is cream white. In general appearance the spike of flowers are like those of Y. gloriosa, but the straight, deep green, sharply pointed leaves carry a suggestion of Y. filamentosa. It appears, from Mr George Paul, that the original plant was found in a bed of seedlings at Loddiges' Nursery, long years ago, and was taken by Canon Ellacombe to his garden at Bitton, where its freedom and distinction made it known to hardy plant lovers as Yucca Ellacombei. Shown by Messrs. PAUL AND SON.

Gaultheria trichophylla.—This is a very low-growing, small-leaved species, of tufted habit, and remarkable for the large size of its Wedgwood-blue berries. Grown in the shade it becomes a handsome plant, but grown in the sun it does not look quite so happy, although it fruits with freedom. Shown by Mr REUTHE.

OTHER INTERESTING PLANTS.

Several interesting Campanulas were shown by Messrs. J. B. GROVE AND SONS, and the one named C. Marion Grove attracted attention by reason of the regular deep blue shading on its pale blue flowers. Messrs PAUL AND SON had Liriodendron tulipifera aureus, which has its leafage almost wholly golden, and therefore very effective. A very long-leaved form of the plant popularly known in gardens as Ficus radicans variegata was shown by Mr. L. B. RUSSELL. Lobelia Erinus compacta Opal, from Messrs. HURST AND SON, should prove a popular bedding form in happier times.

The new, large single Rose named Mermaid, soft yellow, with golden stamens and anthers, shown by Messrs. WM. PAUL AND SON, was admired by everyone; it is a hybrid from Rosa bracteata. Another striking Rose was Elizabeth Cullin, in Messrs. ALEX. DICKSON AND SONS' group; this variety has crimson-scarlet flowers, and is very fragrant. Interesting hardy shrubs shown by Mr. G. REUTHE included Desfontainea spinosa and Abelia floribunda.

GROUPS.

The following medals were awarded for collections:—*Silver-gilt Banksian* to Mr L. R. RUSSELL, for stove plants and seedling Dracaenas. *Silver Flora* to Messrs. H. B. MAY AND SONS, for Ferns and greenhouse flowering plants; to Rev. J. H. PEMBERTON, for Roses; to Mr. G. W. MILLER, for hardy flowers. *Silver Banksian* to Mr. G. REUTHE, for hardy shrubs and Alpines; to Messrs. WM. PAUL AND SONS, for Roses; to Messrs. B. R. CANT AND SONS, for Roses. *Bronze Flora* to Messrs. G. AND W. H. BURCH, for Roses. *Bronze Banksian* to Messrs. J. CHEAL AND SONS, for "Star" Dahlias.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart (in the Chair), Sir Harry J. Veitch, Messrs. Jas. O'Brien (hon. secretary), R. Brooman White, J. Wilson Potter, Walter Cobb, W. H. White, Arthur Dye, W. Bolton, R. A. Rolfe, W. H. Hatcher, J. Charlesworth, J. E. Shill, Chas. H. Curtis, T. Armstrong, Fred. Sander, Pantia Ralli, Frederick J. Hanbury, and C. J. Lucas.

AWARDS OF MERIT.

Odontoglossum Queen Alexandra var. de Barri (Harryanum × triumphans Lionel Crawshay), from DE BARRI CRAWSHAY, Esq., Rosefield, Sevenoaks. The fifth of a very remarkable batch to secure awards, and second only to the large and handsome O. Queen Alexandra Memoria Lionel Crawshay, which was awarded a First-class Certificate last year. The new variety bore a strong spike of many large flowers with broad, yellow sepals, and petals heavily blotched with red-brown. The ample, almost circular labellum is pure white in front, with bright violet blotch and markings in front of the prominent yellow crest.

PRELIMINARY COMMENDATION.

Odontioda Cheribon (Oda. Vuylstekeae × Odm. Mars), from Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells. A distinct new hybrid, with well-formed flowers of large size and fine substance. The sepals and petals are glowing ruby-red, with a gold shade and a few slight white markings in the middle of the segments and on the margin. The broad lip is blotched with dark red at the base, the front white freckled with rose.

GROUPS.

Messrs. STUART LOW AND CO., Jarvisbrook, Sussex, were awarded a Silver-gilt Flora Medal for an extensive group of Cattleyas, Laelio-Cattleyas, Odontoglossums, and Odontiodas. Forms of Laelio-Cattleya Aphrodite and L.-C. Vesuvius and white Cattleyas were conspicuous, and there were many species, including the blue Dendrobium Victoria Regina, Cattleya Rex, and Bulbophyllum barbigerum.

Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells, were awarded a Silver Flora Medal for a well-arranged group of specially fine hybrid Odontoglossums, Odontiodas, and Laelio-Cattleyas, among the last-named being L.-C. Kavala (C. Elvina × L.-C. Epicasta), a compact dwarf plant, with large, rose-coloured flowers, with rich purple lip. Some good forms of Cattleya Warscewiczii, including a white-petalled variety, were well displayed.

Messrs. CHARLESWORTH AND CO., Haywards Heath, were awarded a Silver Flora Medal for a group in which their hybrid Miltonias, including forms of M. Charlesworthii and M. Isabel Sander, were very attractive. Forms of the pretty white-petalled Cattleya Hesta, some handsome Odontoglossums, and the pretty rose-pink Brasso-Cattleya Virgo (B. cucullata × C. Mossiae), were included in the group.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr Thurgood), showed two specimens of the elegant Dendrochilum filiforme, with about fifty slender sprays of small, yellow flowers on each, and Odontoglossum Prince John, a finely-blotched hybrid.

Messrs. FLORY AND BLACK, Orchid Nursery, Slough, showed Sophro-Laelio-Cattleya Vesuvius (S.-L.-C. Marathon × L.-C. Nella), a pretty new hybrid with yellowish-cream sepals, and petals tinged and veined with rose, and bright ruby-red lip.

Mr. J. E. SHILL, The Dell Gardens, Englefield Green, showed a good spike of a fine form of Cattleya Dupreana (Warneri × Warscewiczii).

Fruit and Vegetable Committee.

Present: Messrs. Joseph Cheal (in the chair), W. Bates, Edwin Beckett, H. Markham, E. A. Bunyard, J. C. Allgrove, and E. Harriss.

The group of splendidly grown vegetables so admirably staged by Messrs. Barr and Sons thoroughly merited the Gold Medal awarded. The group was an extensive one, and contained numerous varieties of the several kinds available at this season of the year in a large garden where there are conveniences and labour for the early production of high-class vegetables: the Marrows, Beet, Peas and Cauliflowers were very fine, and a dish of Exhibition Red Potatoes added a good colouring to a notable display.

Messrs. W. S. Seabrook and Sons showed an Apple named Mr. Prothero, a good keeper, and with a brightly-coloured base. Mr. Close showed large-fruited clusters of Red Currants named Laxtonian Red, an abundant cropper, but apparently not readily discriminated from well-known varieties.

NATIONAL CARNATION AND PICOTEE.

July 16.—In very many respects the Carnation exhibition held in the Drill Hall, Westminster, in connection with the R.H.S. meeting on Tuesday last, was a good one. The flowers were of good average size and colour, though a considerable number were just below their best condition.

The Cartwright Challenge Cup offered to the exhibitor making the best display in the open classes was won by Mr. James Douglas, who also secured the Martin Smith Memorial Challenge Cup by obtaining the highest aggregate number of points in the first division of the schedule. The two gold medals offered for the highest aggregate number of points obtained in the second and third divisions of the amateur section were won by Mr. J. J. Keen, Southampton (Hon. Sec.), and Mr. C. S. Webb, Thornton Heath, respectively.

New Varieties.

The Society's Certificate was awarded to each of the three following border varieties, all of which were shown by Mr. James Douglas:—

Purity.—A broad, flat-petalled, pure white self variety, of fine substance and good form.

Mrs. S. G. Murray.—A white-ground fancy variety, with heavy markings of rich, deep violet-purple colour.

J. J. Keen. A heavy-edged white ground Picotee, rather small, but with very broad, rounded petals; the heavy edging is deep maroon-scarlet.

Open Classes.

In the first half-dozen classes six varieties were required, three blooms of each, staged in vases, with Carnation foliage. For bizarres and flakes Mr. James Douglas and Messrs. A. R. Brown, Ltd., were placed 1st and 2nd respectively, and occupied similar positions for white-ground Picotees, selfs, fancies, and yellow-ground Picotees. The six fancies shown by Mr. Jas. Douglas, i.e., Lt. Shackleton, Mona Skirmisher, Lord Steyne, Linkman, and Queen Eleanor, were very handsome specimens.

Some of the best flowers in the show were to be found in the series of colour classes provided for six blooms of one variety, staged in one vase. Mr. Jas. Douglas won the 1st prize for a buff or terra-cotta variety with Elizabeth Shiffner; for a heliotrope variety with The Grey Douglas; and for a yellow-ground Picotee with Eclipse (very fine); and for a white self with Albion. Mr. Lakeman was 1st for a rose or pink self with Hilda Bick; for a maroon or crimson self with Mrs. G. Marshall; for a yellow self with fine specimens of Border Yellow; for a fancy variety with the gorgeous Paquita; and for a white ground Picotee with Montrose. Miss Shiffner led for a red or scarlet self, with Jean Douglas.

Messrs. A. R. Brown, Ltd., had the best twelve show flowers, staged on cards; their blooms of Dick Swiveller (rose flake) and Master Fred (bizarre) were adjudged premier blooms. The same firm gained the 1st prize for a dozen Picotees shown on stands.

Amateurs' Classes.

In the amateurs' section Mr. J. J. Keen, Southampton, excelled in the class for flakes and bizarres, three varieties, three blooms of each, in vases. Merton and Fred were adjudged premier blooms; 2nd, Mr. Jas. Fairlie. Mr. Keen beat Mr. Frostick, Norbury, in the class for Picotees.

The 1st prize for three selfs, three blooms of each, was awarded to Mr. Robert Morton, Woodside Park, who had charming boxes of Purity, Firemist, and Peach Blossom; 2nd Mr. Shiffner, Lewes. Mr. Morton was also successful in the class for three fancies, staging Linkman, Lt. Shackleton, and Pasquin in the form; 2nd, Mr. Frostick. Mr. Morton was also the 1st prize winner in the class for three Picotees. Miss Shiffner led for red, and a good Picotee.

In the third division amateurs, the leading prize winners were Mr. S. C. Webb, Thornton Heath, and Mr. S. McKinstry, Fulham.

NATIONAL ROSE.

Concluded from p. 19.

Nurserymen's Classes.

The premier position, with Champion Trophy as the principal class for nurserymen was won by Messrs. B. R. Cant and Sons; the seventy two blooms were not large, but bright in colour; a few of the finer specimens were George Dickson, Margaret Dickson, Avoca, Souv. de Henry Graham, Mrs. Sam Ross, Lieut. Chaure, Naarden, Mrs. Wemyss Quin, Mrs. George Shawyer, Mildred Grant, and the bloom of Muriel Dickson which attracted the attention of Queen Alexandra; 2nd, Messrs. D. Prior, 3rd, Messrs. F. Cant and Co. For forty eight blooms the honours fell in order of mention to Messrs. G. and W. H. Burch, Messrs. Hugh Dickson, Ltd., and Mr. Elisha J. Hicks. For twenty four blooms Mr. Henry Drew and Messrs. Jarman and Co. were placed 1st and 2nd respectively.

The H'Obrain Cup for eighteen Teas or Noisettes was won by Mr. G. Prince, who was closely followed by Messrs. D. Prior and Sons and Mr. Henry Drew. Messrs. B. R. Cant and Sons led for a dozen blooms of Roses distributed since January 1, 1914, and they showed Mrs. Bertram J. Walker and W. G. Gaunt, 2nd Mr. Elisha J. Hicks.

The Turner Cup offered for the best three dozen bunches of decorative Roses was won by Messrs. Frank Cant and Co., who staged Rouge Angevine, Mme. Colette Martinet, and Rosa Mundi in fine form; 2nd Messrs. Alex. Dickson and Sons. Mr. Geo. Lilley, Messrs. G. and W. H. Burch, and Mr. Elisha J. Hicks were placed as named for twelve bunches of decorative Roses. The best display of Polyantha Roses was staged by Mr. Henry Drew.

Messrs. D. Prior and Sons won 1st prize for three baskets of cut Roses, followed by Mr. Elisha J. Hicks, while in the larger class for seven baskets of blooms Messrs. Alex. Dickson and Sons won 1st prize with "K. of K." and other handsome varieties; 2nd Messrs. Hugh Dickson, Ltd.

Messrs. Paul and Son were awarded 1st prize for a fine group of Roses; tall standards of Lady Gay towered gracefully above large sprays of garden varieties and bowls of specimen flowers.

Mr. Elisha J. Hicks led in the class for a large group of cut Roses and his gorgeous display had as the ground of tall pillars of Rush Rambler, Scarlet, and American Pillar, with great sheaves of Jeanna Bridge, Queen of the Belgians, Florence Forrester, Princess Mary, Chas. E. Shea, and Mrs. George Shawyer in the foreground. Messrs. B. R. Cant and Sons 2nd. For a smaller group the Rev. J. H. Pemberton was placed 1st.

Amateurs' Classes.

The amateur champion for the year is H. L. Wetten, Esq., Oxted, who led among four competitors with large, full, bright and clear blooms of H. R. Clarke, Souv. de Pierre Notting, Lyon Rose, Mme. Léon Pain, Molly Sharman Crawford, Mildred Grant (Silver Medal H.T.), Bessie Brown, Candeur Lyonnaise, Mme. Jules Gravereaux, and the old Mrs. John Laing; Dr. C. Lamplough was a good 2nd, C. C. Williamson, Esq., Canterbury, was 1st, followed by G. Speight, Esq., in the open amateurs' class for two dozen blooms.

The Rev. F. R. Burnside, Great Stanbridge Rectory, won the Elisha J. Hicks Challenge Cup for two dozen blooms, [illegible] exhibit; 2nd, S. W. Burgess, Esq. [illegible].

The amateurs' trophy for Tea and Noisette section was won by Mrs. Bevir, Fortescue, Dropmore, Maidenhead, [illegible] bloom at Mrs. Foley Hobbs being [illegible] vase lovely flowers, and fine specimens of cream of its section; Beauty and Souv. de Pierre Notting were also very good. Rev. F. R. Burnside 2nd, and Dr. C. [illegible], Kirkstall, Alverstoke, 3rd. Capt. Lennox Kitcat, Wimbold Lodge, Newbury, led [illegible] the nine blooms; T. S. Hayes, Esq., D. Prior 2nd, and S. W. Burgess, Esq., 3rd. W. J. Pangbridge, Petersfield, led for [illegible] Noisettes.

The [illegible] in arrangement of Roses, W. H. [illegible], Esq., Withenridge, Beaconsfield, was [illegible] prize.

The [illegible] blooms in other amateurs' classes [illegible] H. J. Matthews, Esq., Stevenage; F. A. Manley, Esq., Northwood; J. Stronell, Esq., Hemel Hempstead; H. L. Wetten, Esq., Oxted; A. R. Reeves, Esq., Gosport; Arthur Johnson, Esq., Bishop's Stortford; P. de Escofet, Esq., Dulwich; W. A. Shipley, Esq., East Dulwich; J. W. Roff, Esq., West Green; Mrs. Bevir, Fortescue, Maidenhead; M. H. Ward, Esq., Epsom; Capt. Kitbee Stuart, Newbury; R. de V. Pryor, Esq., Hitchin; H. B. Darlington, Esq., Potters Bar; H. Courtney Page, Esq., Enfield; and F. R. Roberts, Esq., Dorking.

TRADE NOTES.

SUGGESTED INSTITUTE OF AGRICULTURAL BOTANY.

At an important meeting of the Agricultural Seed Trade Association, held at the Cannon Street Hotel on the 15th inst., Mr. Lawrence Weaver, C.B.E. (Director of Supplies, Food Production Department), gave an interesting address on the aims and objects of the new National Institute of Agricultural Botany which it is proposed to establish at Cambridge. He said they stood at the threshold of a new era in agriculture, because the labourer was now certain of a living wage, and the farmer was approximately certain that he would get an adequate price for his produce for many years to come. Early in October, 1917, the late Mr. Leighton, of Newcastle, Staffordshire, suggested to him that the Food Production Department should institute some sort of control over the selling of seeds, in the interests of the honourable seedsman who was subject to a good deal of unfair competition. England alone of the great nations did not possess an official seed-testing station, but after securing the assent of the Board of Agriculture the seed-testing station was established by Mr. Prothero. An institute on the lines of the Scalof Institute in Sweden was desired, but the question arose as to how it could be financed. Everyone agreed that the work ought to be done and many people thought the Treasury should pay for it, but he felt that an Institute which the agricultural interests had helped to endow would carry far greater weight than one purely official. Moreover, an Institute provided by the monetary assistance of the trade could reasonably ask the Government that it should be consulted in regard to the details of any future scheme of seed control. His first step was to approach Sir Robert Mc Alpine, who with characteristic generosity promised £5,000 down and £1,000 for five years. The Hon. Rupert Guinness, who was an enthusiastic supporter of agricultural research work, gave £1,000, and several friends in the seed trade gave £1,000 each. The National Association of British and Irish Millers had decided to raise the sum of £5,000, and the National Association of Corn and Agricultural Merchants were raising a subscription. He had drafted a trust deed on broad national lines, under which members of the various Associations in the trade would be nominated to the Council of the Institute would be balanced in such a way as to link between the official Government agricultural, the seed trade, and the farmer, and he believed it would be a potent instrument in the great national policy of food production at home

Upon the motion of the President, seconded by Mr. E. Sherwood, the following resolution was unanimously adopted:

"That this meeting of the Agricultural Seed Trade Association of Great Britain and Ireland, having heard Mr. Lawrence Weaver's address on the scope and functions of the proposed National Institute of Agricultural Botany, cordially welcomes its establishment in the interests of British agriculture and of the seed trade, expresses its gratitude to those who have initiated the trust fund with generous benefactions, and invites the members of the trade to subscribe with such liberality that the Institute may be assured of a prosperous career."

Subsequently the Chairman announced donations amounting to ten thousand guineas, and a vote of thanks to Mr. Weaver brought the proceedings to a close.

PROPOSED CHAMBER OF HORTICULTURE.

A PROPOSAL to form a Chamber of Horticulture was adopted at a meeting of the Horticultural Trade held at Dunnington House, Norfolk Street, Strand, on the 17th inst. In all probability this meeting will have a far reaching effect on commercial horticulture, as the formation of a central body to which may be focussed all the weight and interests of the trade will have great influence. The general idea, as set forth by Mr. H. Morgan Veitch and Mr. Geo. Monro, junr., is the federation of all horticultural trade bodies, the formation of a Chamber by means of delegates, and the election of a Council by the delegates. Mr. Morgan Veitch pointed out that at present it was not the special business of any particular person or society to watch the interests of the trade; each society did what it could, but the whole weight of numbers and influence was not brought to bear upon matters of vital importance to the trade. It would be the duty of a Chamber of Horticulture to watch for and fight against irritating and unfair Orders and other measures, and to promote constructive legislation. Moreover, it was pointed out that the position of Horticulture in the commercial world would be greatly improved by means of a central Chamber to which Government Departments could apply for information when legislative measures were being considered.

A quiet and earnest enthusiasm characterised the proceedings, and a sum of £700 was promised, in a few moments, towards the initial expenses. The type of society to be admitted, draft rules, finance, office, and other matters were referred to a committee for consideration and report. This committee, with Mr. H. Morgan Veitch as hon. sec., includes Messrs. Geo. Monro, junr., Alfred Watkins, W. Pomfart, H. G. Lobjoit, R. Wallace, Joseph Rochford, H. O. Larsen, — Evans, and C. H. Curtis. Its duties are merely preparatory.

THE TESTING OF SEEDS ORDER.

ALTHOUGH particulars now have to be given in respect of packets of seeds, sold or exposed for sale the new Order makes one concession as regards small packets. This concession is to the effect that in the case of packets of Pea or Bean seed not exceeding 2 lbs., or of garden Turnip, garden Cabbage, garden Kale, garden Kohl Rabi, Brussel's Sprouts, Broccoli, Cauliflower, Carrot, Parsnip, Beet, or Onion not exceeding 4 ozs., where the germination of the seed sold or exposed for sale is at or above the standard specified in Part IV. of the First Schedule to the Order it shall not be necessary to give the particulars required by the Order. Furthermore, even if the germination is below that standard, it shall be sufficient to state that fact.

Apparently, therefore, the actual figures need not be given in respect of the above small quantities of the particular seeds mentioned.

FRUIT-PICKING IN SCOTLAND.

As in former years, strong efforts are being made to induce school teachers and others to spend part of their holidays in picking fruit, especially for the Blairgowrie district. In order to promote this movement a meeting was held in the Good Hall, Edinburgh, on the 3rd inst. Dr. Mercer presided, and impressed upon those present the advisability of assisting. Mr. J. Hodge, Blairgowrie, stated that every pound of fruit should be gathered. The complaint had often been made that the grower was profiteering at the expense of the picker, yet in some years at least, such as 1915 and 1916, the growers had lost money. Last year they did not make more than 15 per cent., which made an average of about 5 per cent. over three years.

CROPS AND STOCK ON THE HOME FARM.

SPRAYING POTATOS.

THOSE who believe in the advantage of spraying and season and late Potatos will have already sprayed their plants once at least. The long continued spell of dry weather was all against the spread of late blight, but the late weather has at last broken, and those who have not already sprayed their pots would do well to do so without delay. Even if spraying does not prevent an attack of blight, as some aver, it is almost universally admitted that spraying does prolong the growth of the haulm by at least three weeks. If this be true the weight of the crop must be increased considerably, and will compensate for any diseased tubers there may be.

The Food Production Department recommends the use of Burgundy mixture, especially where freshly burnt stone lime is not available for the making of Bordeaux mixture.

Burgundy mixture is made as follows:—

Dissolve 4 lbs. of sulphate of copper (98 per cent. purity) in 5 gallons of water, then make up to 35 gallons. Dissolve 5 lbs. of washing soda in another vessel in 5 gallons of water; warm water may be used to expedite the dissolving of the soda, and when this has been done the soda should be added to the copper sulphate, stirring vigorously meanwhile. If a piece of red litmus paper dipped into the mixture remains red, add more soda, and keep the mixture stirred until the litmus paper just turns blue.

The fungicide should be used in a fresh state, and in no case should it be applied more than ten hours after it has been made.

In spraying thoroughly wet the leaves with the liquid, especially on the under surfaces. The manner in which the specific is applied is of more importance than using a large quantity; just a fine spray is sufficient. For small plots a knapsack sprayer answers well. Where acres are to be sprayed a horse-drawn sprayer is essential.

SWEDES.

Seedling Swedes of the first-sown batch of seed are growing satisfactorily, notwithstanding an attack of Turnip fly when the plants were coming through the surface; the recent showers have accelerated their growth. Directly the plants are large enough to handle they should be "set out," or thinned; much depends on this detail for their future success. I know of no plant that so quickly shows the advantage of early thinning as the Swede. When allowed to remain crowded in the rows the plants are "stunted" in growth and never produce fine roots.

If the weather is dry horse-hoe between the rows and draw wide-open tooth harrows across the rows. This aids not only the hoers when thinning the plants, but hastens growth by disturbing the soil about the plants.

If the seed was good, and sown at the rate of 2 lbs. per acre, there need be no fear of the harrows killing up many of the plants. *E. Molyneux.*

Obituary.

HARRY J. WHITE.—We regret to record the death of Mr. Harry J. White, nurseryman, Worcester. On Tuesday, the 9th inst., he was on a business journey riding a bicycle on the tow-path of the canal, near Worcester, when something went wrong with the machine and he was thrown into the water. His clothing became entangled in the bicycle, and, failing to extricate himself, he was drowned before help could reach him. He was hon. secretary of the Worcester Auxiliary of the Royal Gardeners' Benevolent Institution. Mr. White was 42 years of age, and leaves a wife and one daughter.

MRS. A. KNIGHTS.—The many friends of the late Mr. Peter Barr, V.M.H., of King Street, Covent Garden, W.C., will regret to learn of the death of his second daughter, Mrs. Alice Knights, of Ridgebourne, Christchurch Road, Streatham, S.W., who passed away at the residence of her sister, Mrs. Dunlop-Barr, at Timperley, Cheshire, on the 15th inst.

ANSWERS TO CORRESPONDENTS.

DWINDLED CHINA ROSES: *E. L.* Roses cannot possibly succeed when planted in close proximity to fruit or timber trees, as the roots of these latter will appropriate the moisture and nourishment provided for the Roses. Choose a better site, or, if that is not possible, cut back the roots of the trees and place a piece of sheet-iron in the soil to prevent them from encroaching in the future. If the soil is light add some heavy turfy loam and decayed manure in the autumn and transplant the Roses therein.

GRAPES DISEASED: *K. C. H.* The berries are affected with spot disease (Gloeosporium ampelophagum). Dust the berries and leaves with flowers of sulphur, and again after a interval of 10 days, adding a small quantity of quicklime to the sulphur. See reply to *H. G.* in the last issue.

FREE TRAINING IN GARDENING FOR GIRLS: *W. M. G.* So far as we are aware there is no horticultural school where a girl may obtain free training in gardening. Women students are taken at Swanley Horticultural College; Studley Royal, Glynde, and at University College, Reading; fees, living expenses, and syllabus of training may be obtained on application to the principal in each case. The Education Department of your own County Council may be able to give you further information, as courses of horticultural training for women are now being given in many places.

NAMES OF PLANTS: *J. B. M.* 1, Sedum album; 2, Veronica Traversii; *J. S. Unsworth.* 1, Lupinus commutus (Nipplewort); 2, Epilobium montanum; 3, Brassica nigra (Black Mustard); 4, Euphorbia Lathyris (Caper Spurge); 5, Allium Moly. This latter is the only garden plant; the rest are weeds. *Kent.* Scrophularia arachnoidea (Oldwell Horsleckl), S. Webbiana, Hort. ex C. B. Lehm. and Schnitt sp., and S. tomentosum, C. B. Lehm. and Schnitt sp., are both synonyms of S. arachnoidea. *J. O. Campden.* 1, Lilium elegans; 2, L. Martagon album; 3, Crassula coccinea; 4, Clematis Lady Bovill; 5, Ranunculus asiaticus flore pleno; 6, Pyrethrum Parthenium flore pleno; 7, Lychnis Chalcedonica.

PEAS UNHEALTHY: *T. L.* There is no sign of any parasitic disease in this Pea haulm. The yellowing of the foliage is most probably due to the unfavourable season.

PRIVATE GARDENERS AND WAR SERVICE: *W. T. W.* Place your case before the War Agricultural Executive Committee without delay; present a clear statement of the amount of ground you are cultivating for food production, the amount and kind of help you receive, and the number of people you supply with vegetable food and fruit. Enclose a doctor's certificate of your health, and give particulars of the Tribunal's decision as to grade and temporary exemption. At the same time send a complete copy of your statement to the Food Production Department, 72, Victoria Street, Westminster.

TOMATOS DISEASED: *H. S.* The disease on the Tomato leaves is "rust," caused by the fungus Cladosporium fulvum. Spray the plants regularly with Bordeaux mixture. Remove with a damp cloth any sediment from the wash which is on the ripe fruit before it is used.

It may be possible to secure roots sufficiently large for use by sowing after the first week in August, but seasons vary so much that one can never be sure. There is a temptation to sow at that late time, as usually much ground falls vacant just about the end of August or beginning of September, but the practice seldom pays. Therefore it is advisable that the seeds should be sown not later than the first week in August.

In regard to varieties, as a hardy winter sort I doubt if the old Chirk Castle is to be surpassed for quality and hardiness combined. Roots of the old Green-top variety will keep a long time in good condition, but this sort is not so hardy as Chirk Castle. There are one or two strains of yellow-fleshed Turnips which withstand frost well, and are worth growing for winter use. Much can be done to maintain a supply through October by lifting and storing roots in November.—*James A. Pearce.*

BEETROOT

Beetroot can still be sown, to add to the supply for winter. The soil should be rather rich, and a Turnip-rooted variety selected. Guard against sparrows as the seedlings push through the soil. Thinning must not be delayed. Spray the foliage after a hot day.—*C. Davis, Holy Wells Park Gardens, Ipswich.*

THE ROSARY.

ROSE KEW RAMBLER

Six years ago Rosa Soulieana, a white-flowered climbing species from China, was crossed at Kew with the red-flowered Hiawatha, a Wichuraiana hybrid, and one of the best of the red ramblers. Six plants of the cross are now in flower in the Rose garden at Kew, five of them being white, the sixth, illustrated in fig. 12, a beautiful pink and white. The new hybrid is very free flowering, and the blooms have the valuable property of remaining fresh for a long time, after the manner of American Pillar and Flora Mitten. R. Soulieana has glaucous green leaves, whilst in Hiawatha the leaves are glossy green. The foliage of the hybrid is intermediate between that of the two parents, otherwise the variety might be considered a pink form of Hiawatha.—*W. W.*

PLANT NOTES.

KNIPHOFIA NORTHIAE, BAKER.

When recently at Kew Mr. Watson showed me what he considered the true Kniphofia Northiae, pointing out that many of the plants in cultivation under this name had a midrib on the back side of the leaf which is not present in Miss North's original plant which she gave me (cf. *Bot. Mag.*, tab. 7,412, where it is stated that the plant was found near Grahamstown). I have raised and given away seedlings of this, as K. Northiae, which have a midrib more or less developed in the leaf and the edge of the leaves less serrate, the former character being the only one by which Baker separated Northiae from caulescens Baker, *Bot. Mag.*, tab. 5,946. This was collected by Cooper for Mr. Wilson Saunders on the Stormbergen between Albany and British Caffraria. I have the plant which Mr. Wilson Saunders gave me forty years ago, and as it is now in flower I have compared it with Northiae and with K. Tuckii, Baker, *Bot. Mag.*, tab. 7,644, which came from Colesberg. Though the habit and foliage of these three plants are distinct, and for horticultural purposes K. Northiae is as superior to K. caulescens as that is to K. Tuckii, yet the inflorescence of all three is so similar, that I am certain that no botanist taking broad views of species could separate these three plants on their floral characters alone; and unless their leaf characters remain constant when raised from seed, which does not seem to be the case with Northiae, one must suppose that they represent local forms due to environment. We find precisely similar instances in the genus Agapanthus and in Crinum, which in different parts of South Africa vary much in size and habit, but though their flowers and leaves differ so much in size and colour that gardeners and the older school of botanists treat them as distinct species, the differences are insufficient to distinguish many of the so-called species. I cannot agree with Mr. Baker's remark in *Bot. Mag.* that K. caulescens will never replace the gorgeous K. Uvaria as a border plant, even if it is hardy, which at that time he thought very doubtful. Anyone who saw it as I have it on the top of a rock in my garden would say that it is one of the handsomest of the genus; and the fact that it has survived temperatures below zero here without protection proves its hardiness. Baker also speaks of its "trunk"; this implies to me a woody trunk, which is not strictly correct, for though its habit is more caulescent than that of Northiae, and not herbaceous like that of Tuckii, yet the stem is never woody, and the offsets, if not taken off and planted deeply, lie on the ground and eventually decay. Though the three illustrations referred to, all by Fitch, are good ones, yet my plants do not show the same amount of difference in the bracts below the flowers that his drawings do. K. caulescens and K. Northiae both attain about 4 feet in height, and flower here a month or more before any of the forms of K. Uvaria type, which now vary so infinitely that they must, I think, be looked on as florists' flowers. I may state that in the case of the only one which I have raised for two generations, namely, K. Nelsonii, the progeny of the second generation have trebled in size and lost all resemblance to their original parent. Though this may be due to hybridisation, yet it shows how inconstant the genus is, and how much it needs revision on broader lines than Mr. Baker followed.—*H. J. Elwes, Colesbourne.*

ORCHID NOTES AND GLEANINGS.

CATTLEYA WARSCEWICZII BRITAIN'S QUEEN.

Mr. J. Howes, gardener to Samuel Gratrix, Esq., West Point, Whalley Range, Manchester, sends a flower of a very delicately tinted, nearly white form of C. Warscewiczii, of which he states: "The plant is flowering for the first time, although imported some years ago. It was described by the collector as having 'white sepals and petals and pink lip,' and although it is not a true albino I consider it very distinct."

The flower sent is 8 inches across and of good shape, the silver-white sepals and petals having the slightest trace of Peach blossom tint: the lip is a pale lavender or Peach-blossom colour with a very slight purplish-rose line in the middle of the front lobe, the disc of which is chrome-yellow.

The novelty is a very pretty form and nearest to C. Warscewiczii Mrs. E. Ashworth, illustrated in *Gard. Chron.*, September 4, 1897, p. 163.

TOP-GRAFTING RESULTS.

The top-grafting of trees of undesirable varieties of Apples, which was done under very favourable conditions in April, has answered well this year. The very small percentage of failures can generally be traced to caterpillars eating out the bursting buds. One caterpillar is quite capable of devouring all the buds on a grafted tree if left undisturbed. It has been necessary to examine the trees several times to prevent this destruction. A scion will stand a good deal of ill-treatment once it has formed a junction with the stock, growth being so vigorous. In many

cases where a bud has been eaten out another has pushed at its side.

The worst variety to top-graft, in my experience, is Gascoyne's Scarlet, a thoroughly undesirable Apple for my district, owing to its tendency to canker. A number of trees grafted three years ago have proved an almost total failure. The scions made an excellent start, but soon died off, the bark of the headed stocks bursting away from the wood and turning brown and dry. I have seen this trouble, described as "flooding out," attributed to excess of sap, and the suggestion made that, when heading down rank-growing trees for top-grafting, one branch should be left intact for a season to take some of the sap. This hint was followed when top-grafting some more Gascoyne's Scarlet trees this season, and apparently it succeeded—at any rate, there has been no "flooding out" this time. The only drawback is that insect pests from the old branch may find their way on to the new growth, as caterpillars have done this year.

The common plan of rind or crown grafting never seems quite satisfactory to me, since it does not bring into union the cambium layers of stock and scion—said to be the essential point in all systems of grafting. I have generally adopted the modified plan of lifting the bark on one side only of the cut made on the stock, and taking a thin slice off one side of the scion in order to bring into contact the two edges of the bark. The result is a perfect junction all down that side. The only trouble is that the scion is rather apt to blow out if exposed to strong winds after it has made some growth. This year a new plan has been tried, though quite likely it is not original. The usual vertical cut having been made through the bark of the stock, two more short cuts are made at the top, one on each side of the first. These extend only about ½ inch down from the top of the stock. At the base of them, a short horizontal cut is made, and the two little pieces of bark bounded by these three cuts removed entirely. This leaves the usual long vertical cut with a narrow patch of bark removed at the top exposing the wood. This patch should be the same width as the scion, which is prepared with a single splice cut in the ordinary manner, and then a thin slice is taken off each edge. When the scion is pushed down under the bark in the ordinary way the cambium layers of stock and scion come in contact on both sides at the top, and there is no space down between the bark and the wood of the former. At the same time the lower end of the scion is held firmly under the bark of the stock. Several grafts done in this fashion have been uncovered. In every case a neat junction has resulted, and the scions seem to be firmly clasped, though it remains to be seen how they will stand the test of wind.—*Market Grower.*

CULTIVATION OF CYCLAMENS.

(Concluded from p. 21.)

In five weeks from the time of sowing, two or three-year-old seed will commence to germinate, and when this is observed the paper should be removed and the glass tilted with a small stone or wooden label, until the seedlings push their way through the soil, when the glass may be removed. The seedlings will make good progress during the next three weeks, until the seedling heat is about one inch long, after that stage they will begin to lag, but at this stage the tiny corm is forming its first true leaf, and every encouragement should be given the plants to grow freely by stirring the surface soil carefully with a sharp pointed stick, and spraying them overhead twice each day in bright, warm weather. There are few plants that do not love the sunlight, but the Cyclamen is an exception. The observant grower will find that Cyclamens will develop more growth in one dull week than in three weeks of warm weather and sunshine, therefore it is important to have the houses or frames in which the plants are grown properly shaded. Blinds are certainly the best form of shading, but where these are not available, Summer Cloud answers the purpose very well. When the seedlings show signs of being eaten by pests, a sharp look-out should be made daily for a little, green-coloured caterpillar about ½ inch long, difficult to find, and very troublesome in some districts. The only method of eradicating this pest is to hand pick at night: in the morning the caterpillars are hidden in the soil, but very often return to their work of destruction in the afternoon. Dusting soot on the ashes or gravel on which the pans stand is a good preventive against the attacks of slugs. By the middle of September the lights of the frames should be closed, as the air is much cooler, and during the daytime very little air should be admitted, but the amount of ventilation must depend on the out-door temperatures, as no hard and fast rules can be laid down beyond stating the necessity to prevent draughts and fluctuations of temperature. Towards the end of September the seedpans should be placed in the greenhouse, where they should receive every attention. The ideal temperature for Cyclamens at all times is 55°, but the plants may be grown successfully in temperatures ranging upwards from 45°. By the end of October seedlings from the July sowing should be ready to prick out, but this operation should not be proceeded with until the seedlings have made two or three leaves. Where large numbers of plants are grown 40 seedlings are generally pricked off into 5-inch pots (B's). The best system is to place three seedlings around the side of a 5-inch pot; plants grown in 3-inch pots are less liable to receive a check when being divided for their first potting. The compost for pricking off should be similar to that recommended for sowing the seedlings; a slight dusting of soot may be added with advantage, but not more than a 3-inch potful to each bushel of soil. Subsequent cultural details consist chiefly in keeping the plants clean. Should thrips make its appearance, fumigation will be necessary. Keep the plants at all times in a light, airy position near the glass; do not overcrowd them. No shading will be required after the end of September. Apply water liberally, and spray the plants overhead on fine afternoons. I would repeat the advice to prevent fluctuations of temperature; rather grow the plants in a temperature of 45° than 60°, but remember the ideal temperature for Cyclamens is 55°. Plants thus treated will make fine specimens, ready for their first potting singly by the end of January.—*J. W. Forsyth.*

TREES AND SHRUBS.

ÆSCULUS PARVIFLORA

This member of the Horse Chestnut family, often known as Pavia macrostachya, is a native of the south-eastern United States, from whence it was introduced to cultivation in 1785. Its usual season of blooming is the latter part of July and in August, when few shrubs are in flower. There is no other occupant of our gardens with which it may be confounded, as it forms a shrub from 6 to 10 feet in height or even more, and spreads by means of sucker-like basal growths, but it covers a considerable space. The divided leaves usually consist of five leaflets, which are dark green above and clothed with greyish down beneath. The flowers are borne in erect panicles, in some cases almost a foot in length. The showiest portion of the inflorescence is the cluster of long, thread-like, pinkish white stamens, which stand out prominently. What is not particular is to call Æsculus parviflora flowers best in a fairly deep moist loam that is not parched up during the summer.—*W. T.*

FIG. 15.—ÆSCULUS PARVIFLORA, A DWARF, LATE-FLOWERING CHESTNUT.

DEUTZIA HYPOGLAUCA

Deutzia hypoglauca was not injured by the severe cold experienced in America during the past winter, and has now flowered for three years in the Arnold Arboretum. It is a tall, vigorous shrub, with erect, much-branched stems, lanceolate, long-pointed leaves, dark yellow-green on the upper surface and pale below, and light, orange-brown branchlets. The pure white flowers are seven-eighths of an inch in diameter, and are borne on slender, drooping pedicels in many-flowered compound, round-topped clusters from 3 to 4 inches across. The broad, petal-like filaments, which are rather shorter than the spreading petals, and are notched at the apex, form a tube rising from the centre of the flower from which the bright yellow anthers emerge.

D. hypoglauca was discovered by Mr. E. H. Wilson in Hupeh, but the plants in the Arnold Arboretum were raised from seeds collected in 1910 by Mr. Purdom on the mountains of Shensi, at altitudes between eight and ten thousand feet above the sea-level. This may prove a valuable plant to cross with some of the Chinese Deutzias with rose-coloured flowers. It is a handsomer plant than D. parviflora,

another Chinese species, and an old inhabitant of the Arnold Arboretum, where it has proved to be one of the hardiest of all Deutzias. Sent from the Arboretum to M. Lemoine, at Nancy, France, it was successfully crossed by him with D. gracilis. The result of this cross was Deutzia Lemoinei, one of the handsomest and hardiest garden shrubs of recent creation. One of the forms of D. Lemoinei, Boule de Neige, has been unusually plentiful this season.

PRIMULA SPICATA.

THIS graceful little plant belongs to the Soldanelloides group of the genus, which includes the better-known Himalayan species P. Reidii, P. uniflora, and P. Wattii, as well as the Chinese P. nutans. The species was introduced into cultivation by Messrs. Bees, Ltd., through their collector, Mr. G. Forrest, who found it on the eastern bank of the Tali range in Western Yunnan in 1906. In his notes with the dried specimens Mr. Forrest remarks: "This graceful little plant grows on dry, rocky slopes and on ledges of cliffs in side valleys in sunny situations at an elevation of 11,000 feet." The softly hairy leaves are produced in rosettes, from which spring the flower stems, 4 inches to 8 inches high. The bright blue, fragrant flowers, sprinkled with silver meal and with a white interior, are produced in spikes of from 6 to 9 flowers each. This spicate character is a distinct feature, separating the plant from all other members of this genus.

Like many other Primulas, P. spicata is of a short or biennial character, setting its seeds rapidly after flowering, and the blooms withering off immediately. Fresh seeds germinate freely, and the plant may be grown in places where P. nutans succeeds, that is, a well-drained, partially shaded position, but it does not like too much hot sunshine.

P. spicata obtained the R.H.S. Award of Merit when shown by Messrs. R. Wallace and Co. at the meeting of the Royal Horticultural Society on May 7, 1918. W. J.

FIG. 14.—PRIMULA SPICATA: FLOWERS BRIGHT BLUE.

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

COLEWORTS.—Make another sowing of Coleworts during the present week, to obtain plants for transplanting when the second early Potatos are lifted in August. Plants of this sowing will produce heads of good size by the end of the autumn. Plant out those sown earlier as opportunity occurs, for all vacant spaces should be cropped this year.

CELERY.—Celery may still be planted out, choosing a white variety for early supplies and the red or pink sorts for late use. This crop needs a rich soil and an abundance of moisture, but it is not advisable to plant in over-rich ground or to use water to excess, or the heads will grow coarse and fail to blanch well. Single rows find most favour with growers, and the plan of allowing the plants to become nearly full grown before earthing them up is fairly general.

LEEKS.—Leeks may still be planted in deep holes made in well-enriched soil with an iron bar. Leeks are a most useful vegetable in spring, when the stocks of Onions are exhausted.

SHALLOTS, GARLIC, AND ONIONS.—Where these bulbous vegetables have ripened their foliage the plants should be pulled up and spread on mats to ripen thoroughly before storing them.

WINTER GREENS.—The work of planting all kinds of green crops has made rapid progress since the rains fell. Cabbages which were sown thinly late in April and May have made sturdy plants, and should be put out as the early crops of other vegetables are cleared. Late plantations of Autumn Giant Cauliflowers and Veitch's Self-protecting Broccoli should be made; when the weather remains mild until near Christmas these late plantations are most useful. Purple Sprouting Broccoli should be extensively grown; the plant is very useful, as it fills a gap when the tender white sorts are over. Scotch Kale, Savoys, and other greens should be put out directly ground is available. They may be planted very late in the season, and it is seldom that late-planted or half-grown crops are injured by frost.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

FIG TREES ON OPEN WALLS.—The fruits upon Fig trees against open walls in favourable localities should now be nearing the ripening stage. When at this stage of development do not water too liberally, but, on the other hand, do not allow the roots to become excessively dry; aim at a happy medium. Remove any weak or superfluous growths and do not allow the foliage to shade the fruits, which should be allowed to ripen fully on the trees if for use at home, but if for packing to travel by rail or road pick them carefully a day or two earlier. Encourage young trees to grow freely by watering and syringing them, as red spider may otherwise attack the leaves. If any shoots have developed too vigorously nip out the point.

LOAM FOR FRUIT TREE BORDERS.—Good loam is equally as essential for the preparation of hardy fruit borders as for vine borders, and now is a suitable time to procure a supply. In these unusual times many have allowed their stocks of loam to get unduly low, but it is a mistake to have so little in hand as to run the risk of having finally to use soil of indifferent quality. I much prefer turfy, yellow loam that is so full of fibre as to hold together, and it should be of a calcareous character. If the turf is obtained soon there will be time to make it into a stack that will be fit for use by the end of September. If there is a deficiency of lime in the turf mix bone-meal with it as it is stacked. Should the loam be of too retentive a character add finely broken old lime rubble and small particles of brick. In some large establishments it is a comparatively easy matter to find good loam on the estate, but it is not always easy for the gardener to get the necessary permission to use it. A small amount of well-rotted farmyard or stable manure, well broken down, should be added to the compost used as top-dressings for fruit borders. If the soil needs draining, broken clinkers from the stokehole provide suitable material for the purpose. Where the loam is on hand mix the compost forthwith.

STRAWBERRIES.—Runners that were layered a month ago are ready for severing from the parent plants. Between this period and the time for planting it will be better to keep the runners plunged in their small pots until the ground for planting is at liberty. Let the plants be carefully attended to for watering. Prepare the ground as suggested, a little in advance of the actual planting, and when the weather is favourable tread it lightly. Take an early opportunity of examining the permanent Strawberry beds; remove all runners and weeds, and lightly hoe the soil between the plants. If any particular variety has made too much foliage a few of the leaves may be removed. Should the soil seem exhausted a dressing of well-rotted manure will be beneficial; this material should be lightly forked below the surface. Failing stable manure, I am using Peruvian guano as a top dressing.

ALPINE AND PERPETUAL STRAWBERRIES.—Alpine Strawberries have rarely been more satisfactory as an early crop than during the past six weeks. The flower-spikes in beds that are intended for cropping in the early autumn have all been removed for the last time, and the trusses will now be allowed to develop. Meanwhile we have plenty of fruits on the early batch, and these will maintain the supply. The young stock intended for planting out in the autumn will need attention; remove adventitious spikes and early runners. Our plants are growing in an old frame, so that they can be easily attended to. The plants of Perpetual-fruiting Strawberries should soon be mulched, and runners, unless showing their first spikes, removed. Let the trusses, when long enough, be lightly supported in order to keep the berries well off the soil. As soon as the first berries begin to colour place nets over the plants to prevent birds eating the fruits.

FRUITS UNDER GLASS.

By W. J. GUISE Gardener to MRS. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

TOMATOS.—There is still time to sow Tomato seeds to produce plants for winter fruiting, although I doubt the advisability of growing this crop in view of the shortage of fuel. Plants raised from seeds sown last month should be transferred to 5-inch pots directly they are fit to handle, and placed on a shelf near the roof-glass to encourage sturdy growth; shift them into larger pots as they require more root-space, and continue to afford all the light and air possible. Pot the plants firmly in a compost of fresh fibrous turf, a little mortar rubble and wood-ash. Manure is not necessary.

STRAWBERRIES.—Young plants layered in 3-inch pots, as advised in a previous calendar, should be severed from the parent plants directly the roots reach the side of the pots. Remove the plants to an open and convenient position for their final potting, which should be commenced a few days afterwards. In the meantime prepare the compost as follows. To every four barrowfuls of fresh, strong, maiden loam add one barrowful of manure from a spent Mushroom-bed (or a little more if the soil is light in texture), and four 6-inch pottes of bone-meal. The compost should be turned several times and a light sprinkling of soot added at every turning. The addition of fine lime or mortar rubble is an advantage, in fact I prefer a little extra fine rubble and a little less Mushroom-bed manure, which attracts worms and has a tendency to cause sourness. Pots of 6-inch diameter are in every way preferable to other sizes, and they should be cleansed and efficiently drained. Sprinkle a little soot and mortar rubble over the crocks if fine holes are not available. When transferring the plants to their fruiting pots make a firm base to the ball of roots to rest on. The soil and roots should be moist at the time of potting. Leave sufficient space in the pot to permit of adding fresh compost to a depth of half an inch later. Place the plants close together on an ash bottom that has been well dusted with soot or lime to prevent worms from entering the pots. For a few days the plants may be shaded from direct sunshine, but after they have recovered from the disturbance let them be fully exposed to sunshine. The plants having been well watered through a fine rose, light syringings in the mornings and evenings generally suffice for a short time after they should be examined twice daily to see if more water is needed at the roots.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to SIR JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

PLEIONE.—The Orchids commonly known as Indian Crocuses are in full growth, and well-rooted, strong specimens should receive a plentiful supply of water, and be given weak liquid cow manure occasionally. This treatment should be continued until the foliage shows signs of maturity, when less moisture should be applied, and the use of liquid manure discontinued. When the leaves begin to fade, water should be withheld gradually, and only sufficient given to prevent shrivelling. Pleiones grow best suspended in a light position near the roof-glass in the intermediate house.

ODONTOGLOSSUM.—Plants of the dwarf Mexican species of Odontoglossum, such as O. Rossii, O. Cervantesii, O. aspersum, O. Galeottianum, O. madrense, O. maculatum, and many of their hybrids will now have become active at the roots, and any repotting or resurfacing required should be attended to at this period; shallow Orchid-pans, without side holes, form the most suitable receptacles, and may be suspended from the roof-rafters of the cool house. A suitable compost is equal proportions of A1 fibre and Sphagnum moss (cut up rather short), and a sprinkling of crushed crocks. The materials should be well mixed together. Pot firmly, placing the base of the plant just below the rim of the pan, and finish off with a surfacing of living Sphagnum moss. Afford water sparingly until the roots have grown freely into the new material, and then afford liberal supplies until the growths are complete. When in full growth these Orchids will be benefited by light overhead sprayings, and, being moisture-loving plants, they should be placed in a damp position in the house.

DENDROBIUM.—The cool growing species, D. Jamesianum and D. infundibulum, should as they start into new growth, be repotted or resurfaced as found necessary. These plants may be grown in pans and suspended, or in pots standing on the stage, but in either case it is important that they be kept well up towards the roof-glass, so that they may receive plenty of light. When growing actively they should be liberally supplied with water, but they must be kept rather dry after growth is complete, though never quite dry, as pseudo-bulbs and leaves should be kept in a plump, healthy condition. D. Victoria Regina should be grown in the same house in a moist, shady position; shallow Teak-wood baskets form the most suitable receptacles, with clean Sphagnum-moss as a rooting medium.

PLATYCLINIS.—The pretty Platyclinis filiformis is now in full growth and will soon be sending up its long, thread-like spikes of small yellow flowers; until the flowers open the plants will be benefited by daily overhead sprayings. When P. glumacea has completed its growth it will need very little water at the roots, but must never become sufficiently dry to cause the pseudo-bulbs to shrivel. The leaves should be sponged occasionally in order to keep them free from red spider and other insects. All species of Platyclinis thrive well if suspended or stood near the roof-glass in the shadiest part of the intermediate house. The plants may be repotted just after the flowers have faded, or as soon as new growth is commencing. Pots from the most suitable receptacles, using a compost consisting of equal proportions of A1 fibre, peat-fibre and Sphagnum-moss. After repotting the plants should receive very little water at the roots, merely sprays to the surface of the compost will be sufficient to keep it moist. P. filiformis and P. glumacea do well in the cool house.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of Haddington, Tyninghame, East Lothian.

REMOVAL OF SEED VESSELS.—Delphiniums [illegible] the soil's heat [illegible] to form seeds. The same [illegible] polyphyllus are easy to keep [illegible] flower by cutting out the seed [illegible]. The general effect of this proceeding will be [illegible] delayed. Aquilas and Pæonies must be hand-picked as soon as the seed vessels are seen to be having a prejudicial effect on flower production. A good plan is to pull off every open flower as well as the seed capsules as the inspected beds will, in a wonderfully brief period, again cover the plants with bloom.

BUDDING.—Roses are not so commonly budded [illegible] as was the case 30 or 50 years ago, when it was common to see a bed of Roses for cut-flower standards. Other shrubs besides Roses may be budded now, and it is quite [illegible] important to re-bud some stocks with better varieties. Crataegus may be instanced as a group of great interest that may be budded now on common Thorns.

CARNATIONS.—Layering Carnations may be proceeded with at any time now. Select the best of the current year's "grass" and remove the rest to afford the layers more space to gain strength. A simple method of layering consists in notching the shoots instead of twisting them up or down, according to each method the grower inclines. The shoots are pinned close to the ground, or may be held in position by means of a stone heavy enough to keep it from rising. I have seen quantities propagated in this way with considerably less labour than the usual method.

GLADIOLI.—Short stakes are needed to keep the majority of Gladioli from falling about. One tie is sufficient if the work is performed in time, because the spikes naturally tend to grow upright. Where Gladioli are grown closely in rows a simpler method than a stake to each is to run a wire along the lines (support it by stakes here and there), and tie the spikes to the wire. An application of superphosphate to the surface of the soil will be of great help at the flowering stage, and will also increase the size of the corms. Wherever possible seeds should be saved as seedlings are healthier than offsets, and many may be of great beauty.

PLANTS UNDER GLASS.

By E. BECKETT Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

VIOLETS.—It has been necessary to water Violets frequently this summer, and light sprinklings of water applied previous to watering have kept the plants clean and healthy. This treatment may be continued till the end of the season. Watering or syringing should always be done late in the evening. Disturb the soil between the plants to keep down weeds and remove all runners.

FREESIA.—Bulbs of Freesia [illegible] were forced last season are their [illegible] and may be shaken out of the pots, carefully graded, retaining the best for forcing. They should be placed in a cool, dry shed till required for repotting. Orders for new bulbs should be sent at once, as there is a great scarcity of all kinds of bulbs this season.

THE HOT-WATER SYSTEM.—By exercising great care during unfavourable weather in ventilating, watering and syringing plants in glass houses, the heat may be entirely dispensed with for the next few weeks. During this interval the whole of the heating system should be overhauled and put into good working order. Fuel for the heating of greenhouses will be very scarce during the coming winter, and this fact makes it doubly necessary that the boilers should be put in thorough working order, and all baking, pipes and valves attended to. An effort should be made to procure the allowance of fuel at once. It would also be wise to place under cover fallen tree limbs, to be cut into suitable lengths as required during wet weather. Timber of any kind will make very valuable supplement to the coal [illegible].

BEGONIA GLOIRE DE LORRAINE.—If regular attention is paid to the tying of the young shoots of this decorative Begonia the plants will grow into shapely specimens, and much time will be saved later. Green Bamboo tips and green raffia should be used to obtain the best results, and one stake will be ample except for very large specimens. When the pots are full of roots water the plants occasionally with soot water, and use a concentrated fertiliser. Make the best use of the sun's warmth by closing the house about 4 o'clock in the afternoons, after damping the borders and spraying the plants with tepid water.

THE APIARY

By CHLORIS

SWARMS.—Many bee-keepers are re-starting their apiaries, and have purchased bees from a distance. In these days of slow travelling there is a difficulty in transferring purchased bees to their permanent quarters, as the bees are irritable after utilising the honey with which the honey sac is gorged before swarming takes place. All that the bee-keeper has to do is to recall the honey sac in an artificial manner, and the can be easily managed by placing a quarter of a pint of syrup in a bottle inverted over the covering over the mouth of the skep about half an hour before putting the bees in the hive. In fact, this operation is always advisable when the bees have been in transit for 24 hours or more, and a few teaspoonsful of warm syrup will always make them safer and easier to handle after travelling, even though the journey has not taken the 24 hours. When bees are placed upon frames of foundation only, syrup feeding for a few days will continue to rapid comb construction, and during wet weather it is essential, if the bees are not to die of starvation.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER, *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

APPOINTMENT FOR THE ENSUING WEEK.

TUESDAY, JULY 30—
Roy. Hort. Soc. Coms. Meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 6°.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, July 25, 10 a.m.: Bar. 29.8, temp. 65° Weather: Cloudy.

Trade Re-organisation and Co-ordination.

For some years past commercial horticulture has suffered from the lack of combined organisation adequate to the expansion of the trade in recent times. If we may judge, however, from reports which now reach us from various sources, it would seem that earnest efforts are being made to make up for lost time in this respect, with the result that the trade will shortly have machinery (both constructive and defensive) at its disposal, worthy of the vast amount of labour and capital employed, as well as of the important part which it bears in the national economy.

There was a time, within the memory of many still living, when no organisation worthy of the name was in existence. For instance, in the year 1888, a Board of Trade Committee sat under the presidency of Lord Balfour of Burleigh, to fix the classification of goods for carriage by rail, the rate to be paid for conveyance depending upon the particular class in which goods were placed. With the exception of Mr. Berry (who gave evidence on behalf of Cherries and one or two other fruits), not a single witness appeared to urge the claims of horticultural produce to favourable treatment, and the trade has suffered from that omission for nearly 30 years past!

It is very probable that a new railway classification will be compiled when the war is over, and there are many other difficult problems awaiting solution, in connection with which it is of vital importance that the interests of horticulture should be carefully watched. For instance, the Government is now appointing a Committee to inquire into the whole system of inland transport, and at least one leading article has appeared in the daily Press urging that the railway companies should not be too strongly represented on that Committee. It may safely be assumed that the railway companies are already prepared with their evidence and statistics, but it would appear that at the present moment there is no trade organisation whose duty it is to make similar preparations on behalf of horticulture in all its branches.

Again, for instance, it has been announced within the last few days that after September 1 next no vehicle is to carry on the public roads a load of more than 15 cwt. without a Government licence. Furthermore, there is considerable uneasiness in various trades with regard to such matters as the growing practice of the Government to require persons to take out licences to carry on their businesses; to the increasing powers of Allotment Holders' Associations and Co-operative Societies (who pay no income tax and who claim to be supplied with goods at prices little above wholesale cost); and to the growing tendency of Government Departments to enter the commercial arena, in the capacity of both buyers and sellers, at the possible expense of the ratepayer. Retail is are beginning to feel that they are officially looked upon as an unnecessary medium of distribution, and other important matters await solution in connection with the increasing depletion of horticultural labour and the rise in cost of production due to higher wages and ever growing prices of material. Matters of this kind are no longer left to be regulated by the law of supply and demand, but are controlled by Orders and Regulations which have the effect of Acts of Parliament, issued almost daily.

In these circumstances, it is fortunate that many of the Government Departments are abandoning their historic attitude of reserve, and are showing a welcome readiness to co-operate with recognised leaders of the trade by means of Advisory Committees. This rapprochement of public officials and trade leaders is of the highest importance to both parties. Commercial men are able to gain light as to the difficulty of various problems which Governments are from time to time called upon to face; on the other hand, officials, whose experience in trade matters is perforce sometimes more theoretical than practical, are enlightened as to the peculiar trade conditions, and are thus able to obtain reliable knowledge with regard to the inner working of the delicate machinery with which it becomes their duty to interfere.

Hitherto there has been almost complete lack of co-ordination between the various trade associations which watch the interests of the several branches of horticulture. The result has been considerable overlapping of effort and unnecessary expenditure of time and money, and frequently the Government has been somewhat at a loss to decide which of various trade associations is entitled to speak with authority as representative of the various interests. It is satisfactory, therefore (as was announced on p. 30 in the last issue), that a Chamber of Horticulture is now being inaugurated, which, if properly supported by the trade, will constitute a central body, able to speak and act with one voice on behalf of the various affiliated associations. It is announced that there is no intention of encroaching upon the work already so ably performed by the Royal Horticultural Society on behalf of the science of horticulture, nor is there any intention of interfering with the work of the various trade associations on behalf of their respective sections. These will enjoy a free hand as heretofore, and the Chamber of Horticulture will in effect perform on their behalf the same functions as are exercised by the Railway Clearing House on behalf of the various railway companies. The latter, of course, still manage their own internal economy, but when their interests are threatened, or when the adoption of some constructive policy becomes desirable, the Railway Clearing House enables them to speak and act with complete unity and co-ordination of effort.

It will, of course, be to the advantage of the affiliated associations to increase their membership and set their own houses in order, so that they may secure adequate representation on the Council of the Chamber, and it is satisfactory to learn that this point of view appears to be fully recognised by the trade. The Horticultural Trades' Association of Great Britain and Ireland, for instance, is drastically reorganising its constitution, and is taking steps to form representative Committees in various parts of the country, so that each member of the trade may have a voice in its affairs on the principle of "one man one vote."

Another strong body which has recently come into existence is the United Council of Seed Trade Associations, which devotes itself specially to the interests of the seed section of horticulture and agriculture, and which links up in that respect the Agricultural Seed Trade Association, the Scottish Seed Trade Association, the Irish Seed and Nursery Trades Association, the Liverpool and District Seed Trade Association, and the Irish Wholesale Ryegrass Machiners' Association, in addition to the seed section of the Horticultural Trades Association. Co-ordination, in fact, is in the air, just as agriculturists are already taking similar steps on their own behalf to act through a general Agricultural Council.

In various other respects, strong bodies of this nature may prove to be of incalculable benefit to the nation; for instance, in connection with problems involving reconstruction after the war, and in the development of the commerce of the Empire. It is safe to assume that the German nation already has its machinery prepared in this respect, and it is certainly encouraging to find that the commerce of the British Empire is at last abandoning its time-dishonoured policy of "laissez-faire," and is taking steps to organise itself. Evidently the lessons which have been burnt into the memory of the nation since the year 1914 are bearing fruit.

ROYAL VISIT TO ALLOTMENTS.—Their Majesties the KING and QUEEN paid their long-promised visit to the allotments in South-West London on the 20th inst., accompanied by Mr. ROWLAND E. PROTHERO, the President of the Board of Agriculture, and attended by Colonel CLIVE WIGRAM and Captain BRIAN GODFREY FAUSSETT. The allotments at Putney Lower Common were the first inspected. Here the allotment holders were present with their wives and children, and as their Majesties, who had been received by the civic authorities, passed along the central path, they were able to note the splendid rows of Potatos and Onions, the latter being a special feature. The royal visitors stopped here and there chatting with the allotment holders, who pointed with pride to their crops. Their Majesties next visited the Wimbledon Park Piggeries and Allotments. These allotments represent a great stretch of intensely cultivated ground, flanked by outbuildings wherein pigs and rabbits are fed, in the main, on waste produce from the allotments, which were also inspected. At the London and South Western Railway's power station their Majesties were received by the Chairman of the company, the chief of the power station, and the Chairman of the Allotments Committee, who conducted them to the allotments worked by the men employed at the power station. This land, which was until recently derelict, was covered with splendid crops. The owner of the first prize plot was congratulated by their Majesties, and QUEEN MARY accepted Carrots and Peas from a display of grand vegetables which he had grown. The next visit was made to the Ridgway Place Allotments, Wimbledon. These privately acquired plots are situated on a disused building site, and thanks to the energy of Mr. G. W. DAMPNEY, the Chairman of the Surrey Horticultural Sub-Committee, and Dr. ELLIOTT, the Secretary of the Wimbledon Home Produce Society, the whole of the hitherto derelict area has been turned into splendid allotments. The next visit was paid to Merton Park, where their Majesties were received by the Chairman of the Urban District Council, the Chairman and members of the newly-formed Horticultural Committee for Surrey, and Mr. E. W. JOHNSON, Master of the Merton Schools, who conducted their Majesties round the allotments cultivated by the boys of his school. These school allotments comprise half an acre, and are worked on a commercial system by means of five classes, each consisting of fourteen boys from the school, which is quite right. This good work is only typical of what is being done over the whole of Surrey, in which county there are over 200 similar school gardens. Their Majesties next visited Tooting and Battersea Rise on the north side of Clapham Common, and were received by the Mayor of Battersea, the venerable Town Clerk, and the Chairmen of the various Allotments Associations. These gentlemen escorted the KING and QUEEN through the plots. Their Majesties chatted with the men, their wives, and children, admired the splendid rows of Peas and Potatos, and asked many and varied questions. His Majesty especially noticed the Vegetable Marrows, pointing out their usefulness for jam making in this year of fruit scarcity. With this visit the greatest day the allotment movement has ever had came to an end.

RESIGNATION OF LORD LEE.—At the moment when the first fruits of the strenuous and successful campaign of increased food production are maturing, the Director General of the Food Production Department has found himself compelled for reasons of policy to resign his appointment. Those who know how strenuously and unremittingly the Department has laboured to perform its task, and who appreciate the fine qualities of leadership which Lord LEE has shown, will learn of his resignation with deep regret; nor will they be able to conceal their apprehension lest the great programme of cultivation with which his name is identified may suffer from the absence of his guiding hand and energetic personality. Horticulturists—as has been pointed out elsewhere in these columns—have special reasons for gratitude to Lord LEE, who, from the day of his assumption of office, has shown clear and practical recognition of the important part which intensive cultivation must play in any scheme devised with the object of making this country more self-supporting with respect to food supplies than it has been in the immediate past.

HONOUR FOR SIR DANIEL MORRIS.—At the graduation ceremony of the University of Wales, held at Cardiff on Friday, the 19th inst., the degree of Doctor of Laws, Honoris Causâ, was conferred on Sir DANIEL MORRIS, K.C.M.G., in recognition of his scientific services to tropical agriculture.

ESTABLISHMENT OF NATIONAL FORESTS IN THE UNITED STATES.—Under a law passed in 1911 President WILSON has established, by proclamation, 5,000 new forest reserves in the Eastern United States. One at White Mountain covers about 300,000 acres in Maine and New Hampshire; the second, Shenandoah, occupies 165,000 acres in Virginia and Western Virginia; and the third, Natural Bridge, also in Virginia, has an extent of 90,000 acres. Previously the only existing national reservations were the Pisgah and Alabama forests.

WART DISEASE OF POTATOS: TRIALS AT ORMSKIRK.—In view of the great importance of planting only immune varieties of Potatos in land infected with or threatened with wart disease, Potato growers are invited to visit the Ormskirk Potato Trials, which will be open to the public on August 1, 2 and 3. The trials include the testing of over 500 varieties for immunity from wart disease, and are being conducted in the fields of the Ormskirk Poor Law Institution, which is within a short distance of Ormskirk railway station. The grounds will be open each day at 11 a.m., and Mr. J. SNELL, Inspector of the Food Production Department of the Board of Agriculture, who is in charge of the trials, will be in attendance to give information to visitors.

FOOD PRODUCTION IN MESOPOTAMIA.—The Euphrates irrigation scheme, so intimately connected with the Hindeh barrage designed by Sir WM. WILLCOCKS, and finished before the war, was not utilised by the Turks, and the canalisation work was never completed. Now, however, as a result of digging out about a hundred disused canals on the Hillah branch of the Euphrates during the past winter months, no fewer than 500,000 acres of land have been brought under cultivation, and the harvest promises to be a large and valuable one.

ELECTRICITY AND PLANT GROWTH.—It is of interest to note that recent investigations by Messrs. JOHNSON AND STILES into the history of electrical experiments on plants prove that the first experiments on the influence of electricity on the growth of plants were made as far back as 1746 by Mr. MAIMBRAY. Most modern research in this direction has followed on the lines of the

FIG. 38.—RHODODENDRON ROYALE (SYNSTIGMA). FLOWERS CRIMSON. (See p. 38.)

experiments of permanent, and, according to Messrs. JOHNSON and STILES sufficient care has not been taken to measure the electrical discharge, nor has it been fully realised that the stimulating effect may depend not only upon the intensity and time of the discharge, but also upon the particular stage of growth reached by the plant or crop treated; moreover, the influence of the electrical discharge may appear long after its application.

POTASH FROM SUNFLOWERS.—Those who grow Sunflowers should bear in mind that the ash obtained from the plants after the seed has been harvested is, owing to its richness in potash, a manure of considerable value. Of the ash obtained from burning the Sunflower stems, leaves and heads, 62 per cent. consists of potash, and as an acre of Sunflowers produces from 2,500 to 4,000 lbs. of top, the total yield of potash is considerable. Allowing 3,000 lbs. of top there would be produced 160 lbs. of ashes per acre of crop, which should contain upwards of 50 lbs. of potash. After the seed crop has been gathered,

therefore, the tops of the plants should be collected and burnt, care being taken to choose a dry day. The ash should be stored in a dry place until required for use as manure for Potatos or other root crops in the following year. It should be spread over the ground before the Potato crop is planted at the rate of from ½ to 1 oz. to the square yard.

VEGETABLE EXHIBITIONS NOT TO BE TAXED.—The Board of Customs and Excise is our authority for stating that vegetable exhibitions (as opposed to flower shows) are exempt from the payment of entertainment tax, provided such exhibitions are not managed as a source of profit, nor converted into entertainments by means of bands or extraneous amusements.

ONION CULTIVATION IN THE BRITISH VIRGIN ISLANDS.—From a report on the Agricultural Department, British Virgin Islands, we gather that about a third of an acre was planted with Onions at Tortola Experimental Station, at the end of 1915. The weather conditions were not favourable at the time of seed sowing, but subsequently improved. Although no special cultivation was given, the crop of dry Onions amounted to 3,183 lbs., or at the rate of 9,564 lbs to the acre. The entire crop was purchased by the Tortola Onion Growers' Association for £12 15s., or at the rate of £38 5s. per acre.

SILAGE FROM SUNFLOWERS.—The value of the Giant Sunflower as a silage crop is discussed in the March number of *The Journal of Heredity* by F. B. LINFIELD, the Director of the Montana Agricultural Station. Trials were made of this plant in the higher valleys, where Beans and Maize were not well adapted owing to the uncertainty of their yield. In three successive years the yield of the Sunflower varied from 22-30 tons of green fodder per acre, being about 2½ times that of Maize, and more than twice as great as that of Lucerne, for the season. It had, moreover, the advantage of so shading the ground as to keep all weeds well under. Feeding experiments were made with it, both as a green crop and as silage. Cows were found to eat it as readily as Maize fodder, and control experiments showed that the milk flow was maintained as readily as with the latter crop; nor was there evidence of any taint in the milk. A portion of the Sunflower fodder was put into the silo and fed in the winter, both to cows and fattening steers, with satisfactory results. Unfortunately a chemical analysis of the green crop was prevented through the destruction by fire of the Department's laboratory. The author states that further experiments are in progress. Meanwhile it might be worth the attention of agriculturists in this country as a crop for silage. It matures in this climate better than Maize, and, consequently, would not be so liable to become sour in the silo. At the same time its relatively high oil content would probably render it valuable at a time when cake is so scarce.

A NEW STRAIN OF ASPARAGUS.—According to the United States Department of Agriculture a new and distinct strain of Asparagus has been raised by Mr. J. B. NORTON, an expert in the Bureau of Plant Industry. It is the result of ten years' work in cross-breeding and selection; its chief merits are uniformity of growth, increased productiveness, and a greater power of "resistance" as compared with older varieties.

RHODODENDRON ROYLEI.

THE name may not be approved by botanists, who sunk R. Roylei under R. cinnabarinum, but it stands firm with gardeners, who, quite reasonably, refuse to call the dusky beauty by the same name as the smaller-flowered orange or madder-coloured one. There are differences, quite bigs ones too, in the foliage of the two plants. The trouble is that other Rhododendrons of like character, bearing such names as blandfordiaeflorum, thibaudiense, pallidum, and intermedium have to be reckoned with. Still another is that illustrated in fig. 15, which Mr. Reuthe has had for years, and has obtained an Award of Merit for under the name of Roylei magnificum. It is a fine form, certainly the best Roylei I have ever seen, and I have seen many in Cornwall, Wales, Ireland, Leonardslee, and Kew. The flowers are of large size, very dark crimson in colour, with a sheen which in certain lights is almost silvery. Mr Reuthe probably knows the origin of his plant, I do not. Like the others mentioned, it is hardy enough to be quite happy out-of-doors in the neighbourhood of London, and it blooms in June and July, so that frost does not mar its beauty. I should say that Mr. H. J. Mangles used a good dark Roylei to cross with calophyllum when he bred the lovely hybrids H. J. Mangles and Rose Mangles, which, at Littleworth Cross, have for years been given a house to themselves, and when in flower are more like big-flowered Malayan Rhododendrons (Vireya) than Himalayan. Rose Mangles flowered in the Temperate House last year as I have never seen it anywhere else, and for weeks I was ready to declare this was the most lovely Rhododendron I had ever seen. I gave Mr. Reuthe a guinea for a little plant of his magnificum about five years ago, after seeing it at the Chelsea Exhibition, and it was not dear at that price. *H. Watson.*

HOME CORRESPONDENCE.

The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

AMERICAN BLIGHT (see pp. 13, 28). — In December, 1915, one of your correspondents asked if there was any foundation for a report that Nasturtiums were destructive of American Blight. There was no reply, but I tried growing them on spoilers with marked success, in 1916 and 1917 the aphis almost entirely disappearing. This year I trusted to self sown plants, and they have not come up as well as I expected, and there is a small amount of the blight. I do not think the method will be effective in the case of large standard trees, as the Nasturtiums do not grow more than 7 or 8 feet high. *Arthur D. Nix, Mount Charles, Truro.*

—— I have never found spraying of much use for the destruction of woolly aphis, as it is necessary to penetrate the protective covering of "wool." For the past three years I have been experimenting with creosote, applied with a stiff paint brush. Half a badly infested Apple tree was treated with creosote, the remainder with paraffin. The paraffin treatment was partially successful, the creosote wholly so. So successful was it that I advised the application of a mixture of clay and creosote to Vines here (whilst dormant), so infested with mealy bug that the Grapes were uneatable last season. This season there is scarcely a bug to be seen in the vinery, and the Vines are much stronger in growth. The advantages of "creosote and clay" are: (1) It is cheap; (2) ready for use; (3) has great penetrative powers; (4) dries quickly. The use of this specific is a great advantage over poisons where birds or animals are kept. *C. F. Bridgett, Red Roofs Gardens, Teddington.*

MANURE FOR VEGETABLES (see p. 28).—Mr. Brotherton states that soot and poultry manure are better than sulphate of ammonia for Onions. This is naturally the case, since the only matter of manurial value in soot is sulphate of ammonia, but the poultry manure is very valuable, being rich in other plant foods. It would seem that sulphate of ammonia and poultry manure would be the better combination, and the addition of wood ash or sulphate of potash would be a better balanced artificial still. I have seen it stated that Onions stimulated with sulphate of ammonia or nitrate of soda lose their keeping qualities unless potash in some form is also administered, and I am of the opinion that this is true. *D. King Page, 25, Thicket Road, Anerley.*

A GARDEN WAR MEMORIAL.—In a garden in the East Riding of Yorkshire I recently visited I noticed a stone some 9 inches by 6 inches let into the wall outside one of the greenhouses, with the following inscription: "John Thacker, aged 18 (worked in these gardens). Killed in France, March 21, 1916." Such a memorial is an appropriate appreciation of the sacrifices which are being made by brave men for their country. *T. A.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

JULY 2.—*Present:* Mr. E. A. Bowles (in the chair), Col. Rawson, Dr. Rendle, Messrs. W. Hales, Bennett-Poe, Odell, Allard, Fawcett, Fraser, Worsdell, and F. J. Chittenden (hon. sec.).

Poppy Roots invaded by Grubs.—Mr. Fraser showed roots of Papaver orientalis invaded by the larvae of a burrowing beetle, probably a species of Otiorrhynchus, which had caused the death of the plants. Eelworms were also present, but they were of a non parasitic nature.

Coloration of Leaves.—Col. Rawson showed leaves of Virginia Creeper brilliantly coloured at the edges where sunlight had passed other leaves and fallen upon them. He also showed a Poppy of the Mikado type which had appeared in his garden apparently from seed of the common white form of the opium Poppy. This change he attributed to the incidence of certain rays of light.

Caterpillar Attack on Aconite.—Mr. Odell showed the cocoons of the moth Plusia moneta, which attacks Aconite. The insect was apparently introduced about fifteen years ago, and has spread widely since.

Thalictrum Chelidonii.—Mr. Allard showed a plant of Thalictrum Chelidonii, a large-flowered species from Asia, not at all common in gardens.

Various Plants. Mr. Bowles showed plants of Lilium candidum from Salonika with more leathery leaves than is common, and more crateriform flowers. He also showed Contranthus angustifolius which he had collected at Modane, and a hybrid between it and C. ruber.

Insects on Mistletoe Flowers. — Dr Rendle brought a list of insects caught by Mr. Bowles on Mistletoe flowers this spring. The insects, as determined by Mr K. G. Blair, were as follows: Diptera: Simulium reptans, 2 ♂♂; Musca corvina, ♂; Scatophaga stercoraria, 2 ♂♂, 3 ♀♀; Limnophora septemnotata, 1 ♂, 4 ♀; Leptis nigripes, 2 ♂; Chloropisca notata, 4; Phora, sp. 2; Hymenoptera: Ichneumonidae, 1; Phytogota: Capsidae, 1.

JULY 16.—*Present:* Mr. E. A. Bowles, M.A. (in the chair), Dr. A. Voelcker, Messrs. J. Fraser, W. C. Worsdell, H. J. Elwes, Col. H. C. Rawson, W. E. Ledger, and F. J. Chittenden (hon. sec.).

Abundance of Poppies.—Dr. Voelcker drew attention to the remarkable abundance of the common field Poppy in Wheat fields this season, and especially upon a plot in the Woburn Experimental Farm where Wheat following Tares fed off with sheep was a poor plant, while Poppies were abundant; on the adjoining plot where the treatment was the same except that Mustard had been fed off instead of Tares, the Wheat was a good crop and Poppies practically absent.

Scalade attacked by Gall Weevil. Mr Fraser showed a specimen of Scalade stem with a chain of galls several inches long, produced by the gall weevil (Centorrhynchus sp.). These galls are usually found only at the ground level.

Doubling of Various Flowers, etc. Col Rawson exhibited further specimens of Poppy flowers showing colour and form changes which had arisen in his garden, and which he attributed

to exposure to certain light rays. He called attention to the change of stamens into petals in the doubling of the Poppy, and to the presence of inverted spurs in double Aquilegias and Tropæolums from his garden.

Excrescence on Cauliflower.—Mr. W. C. Worsdell showed a developing inflorescence of Cauliflower in which the group was composed not as is usual of a mass of hypertrophied flower stems, but of thousands of flower buds with a few leafy bracts among them.

Disappearance of the Bee Orchis.—Mr. H. J. Elwes remarked upon the scarcity of information regarding the life histories of British Orchids, and gave an instance of the remarkable appearance of flowering plants of Bee Orchis last year in a wood cleared four years before, whereas this season none is to be found.

Proliferation in Echeveria setosa.—Mr. W. E. Ledger showed a plant of Echeveria setosa from his garden in which the flowering axis in one case bore a rosette of leaves at its tip without flowers, while in another a flowering shoot sprang from just beneath the rosette.

Curled Mustard.—Mr. A. Ireland sent a plate of the Chinese Curled Mustard, which he said he had found to make an excellent salad, and very good food for rabbits. The plant he had found as a weed in waste places; it is easily raised from seed sown in April.

Tall Antirrhinum.—From Mrs. Wilson of Merstham, Surrey, came an account of an Antirrhinum which had attained the height of 6½ inches. This was apparently a further instance of the occurrence of a giant race of these plants such as has previously been brought before the Committee, and would doubtless breed true if self-fertilised.

Spadix Lesion in Tobacco.—Mr. E. M. Holmes sent a remarkable specimen of Aberdeen officinalis with fasciated and spirally twisted stem 6 ft. 2 in. inch in breadth. He also sent a specimen of the inflorescence of Aegopodium sylvaticum with numerous beaks, bracts among the flowers.

Cultivated Sparrow.—Some discussion took place regarding the Sparrow grown on the Continent for feeding sheep. It is sometimes distinguished by agriculturists from Spergula arvensis under the name of *S. maxima*, but is usually regarded as a form scarcely meriting a varietal name of that species.

TRIALS AT WISLEY.

The following awards have been made by the Royal Horticultural Society after trial at Wisley:—

AUTUMN SOWN LETTUCE.

AWARDS OF MERIT.

Brabazon White Winter, sent by Messrs. Barr and Sons.

Stanwood Park, sent by Messrs. Nutting and Sons.

HIGHLY COMMENDED.—Commodore Nutt, sent by Messrs. Sutton and Sons; Immense Hardy Green, sent by Messrs. E. Webb and Son; Tom Thumb, re-selected, sent by Messrs. J. Carter and Co., Barr and Sons, and Robert Sydenham, Ltd.; Tremont Winter, sent by Messrs. Barr and Sons; White Madeira, sent by Messrs. Barr and Sons; Wonderful, sent by Messrs. E. Webb and Son; Yates' Winter, sent by Messrs. Barr and Sons.

COMMENDED.—McHattie's Giant, sent by Messrs. Kent and Brydon; Schofield's Hardy Winter, sent by Messrs. Barr and Sons.

HERBACEOUS PÆONIES.

AWARDS OF MERIT.—*Duchesse de Nemours* No. 85, sent as alba sinensis, both by Messrs. T. S. Ware, Ltd.; Nos. 90, 111, *festiva maxima*, sent by Messrs. Ware and Messrs. Kelway and Son; Messrs. Kelway's plant was sent as Hon. Mrs. Portman; *Lady A. Duff*, sent by Messrs. Kelway and Son.

HIGHLY COMMENDED.—Dawn, sent by Messrs. Barr and Sons; L'Elégante, sent by Messrs. T. S. Ware, Ltd.; Marshal Oyama, sent by Messrs. R. H. Bath and Co.; Mme. Crousse, sent by Messrs. R. H. Bath and Co.; (129, 130) Mons. Chas. Lévêque (syn. Mlle. Léonie Calot), sent by Messrs. R. H. Bath and Messrs. T. S. Ware, Ltd.; The Marquis, sent by Messrs. Kelway and Son; Virginie, sent by Messrs. R. H. Bath, Ltd.

COMMENDED.—Pride of Langport and Rosea both sent by Messrs. Kelway and Son.

ROYAL SCOTTISH ARBORICULTURAL.

JULY 3.—A general meeting of this Society was held at 5, St. Andrew Square, Edinburgh on this date, the Duke of Buccleuch, K.T., President, in the chair.

The following resolution, which was moved by Mr. A. D. Richardson, and seconded by Mr. Robert Allan, was adopted by 45 votes to 3, and it was agreed to send it to the Cabinet Committee considering the question, to the Prime Minister, the Minister of Reconstruction, the Secretary for Scotland, the Development Commissioners, the Board of Agriculture, and the Scottish Members of Parliament:—"That this general meeting of the Royal Scottish Arboricultural Society welcomes the announcement that a Committee of the Cabinet has the question of forestry administration under consideration. The meeting desires to impress on Lord Curzon and Mr. Barnes the paramount necessity of placing the Central Control of Forest Policy under men conversant with the subject; of freeing the local administration in Scotland from the subservience to agricultural administration under which it has hitherto laboured; and of making immediate progress with the replanting of cleared areas and the planting of large additional areas, so that public opinion may be satisfied that steps are being taken to protect the country from the grave national danger of a timber famine in the future. The meeting respectfully requests the Government's representative, Mr. Master of Rosebery, to ensure that this Society should have an opportunity of considering and expressing its views on the subject of [illegible] before it comes [illegible]."

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

JULY 11.—The monthly meeting of the above Society was held at the R.H.S. Hall, on Monday, the 8th inst., Mr. Chas. H. Curtis presided. [illegible] were received. The receipts [illegible] £19 5s. 6d., expenditure for the month £7 3s. 10d. from these figures it will be seen that the sum of £21 1s. 8d. was passed for payment to the members of the deceased members [illegible] £1 1s. 8d., [illegible] £17 6s. 6d. and [illegible] £3.

TRADE NOTES.

NEW STOCK FOR ROSES.

As the importation of Manetti stock from Holland and France is now prohibited in America Rose growers in the United States have to decide which is the best home-raised Rose stock for their extensive use. At East Northport, New York, Mr. J. W. Kruckman has experimented with Rosa multiflora japonica and with so much success that he has sown 50 lbs. of seed obtained from Japan. There are said to be 350,000 to 400,000 seeds in the pound of seed, which, a hundred sample gives 200,000 seeds to the lb. Mr. Kruckman reads of his results with a good deal of what may prove to be a new American industry.

SALE OF A NURSERY.

WARD'S NURSERIES, Hanworth, Middlesex, and freehold estate, of about sixty acres, are to be sold by auction at The Mart, Tokenhouse Yard, E.C., on Wednesday, July 31, at 2 p.m. The estate, with the large building containing packing shed, offices, bulb store and seed shop, stabling for seven horses, a cart shed, a four-roomed cottage, and twenty-nine greenhouses, will be sold as one lot. The purchaser will have the option of taking stock and fittings at valuation, and if such option is exercised the goodwill of the business will be included in the sale.

CROPS AND STOCK ON THE HOME FARM.

MUSTARD.

Of all cattle crops grown on the farm Mustard is the most useful, in that it is more certain of success than any other plant grown for the purpose on any kind of soil or in any situation. It can be used as food for sheep in the place of other food, or it may be ploughed in as a green manure, so that it is equal to manure in preparation for cereal crops, especially Wheat. A crop of Mustard is especially valuable as a preparation for Wheat on a field that has been summer-fallowed with the object of cleaning it of Couch, Thistles, Docks, or Coltsfoot. The last named is especially troublesome in some districts, and difficult to eradicate by any other form of cultivation. Assuming such a field has been ploughed several times during the summer, cleaned, and sown to Wheat in October, Mustard is an excellent substitute for farmyard manure. Sow evenly about the second week in August 2 lbs. of Mustard seed per acre with a hand seed-barrow, and harrowing the ground afterwards. So quickly does the seed germinate, even if the surface has not a fine tilth, there need be no fears of failure. In ten weeks' time, given normal weather, the Mustard plant should be from 1 foot to 2 feet high. If other sheep food is scarce the Mustard can be fed off to sheep, or ploughed in, pressed, and sown with Wheat at will. Sometimes the Mustard attains a height of 3 feet before ploughing can be done. At this height it is difficult to bury effectively. A light roller drawn over the crop in front of the plough facilitates the burying of the plants. A more simple plan is to attach a weight by a piece of chain 2 feet long to a plough, allowing it to drag along the furrow, thus pulling in the tops of Mustard plant [illegible] other crops remain unburied.

CABBAGE.

Cabbages are now growing freely. The most expeditious way of planting large numbers of seedling Cabbages, especially if the plants are leggy, is to plough them in in every third ordinary 9-inch furrow, afterwards drawing a light roller over the surface to make the soil firm about the roots. Reject any plants showing the least signs of clubbing at the roots.

Those plants established will be accelerated in their growth by loosening the soil about them with a horse hoe or a "Planet" cultivator, cutting in weeds and admitting air to the roots. Established plants that require a fillip to growth should be given 1 cwt. of sulphate of ammonia per acre, sowing the fertiliser evenly over the plot.

When the soil is very dry, the best method of planting Cabbages is to water the sites before planting each seedling. When this is done, dibbling in the plants afterwards is an easy matter.

HIGH GRADE BASIC SLAG.

If it were necessary the present season has proved the value of a high grade sample of this fertiliser as compared with the results obtained from a low-grade quality.

Last December I applied 3 cwt. per acre of 40 per cent. basic slag on various plots of grass which have been in existence over 100 years, and on which this artificial had not been applied for at least six years. The result in the increased yield of grass, and especially of the finer types, commonly known as "herbage," was remarkable. The field produced an excellent crop of hay, which has no equal as food for dairy cows. In comparison with results in former years from basic slag of 30 per cent. grade there is a wide gain in the use of the higher grade samples.

Apart from its intrinsic value, the cost of transit and application is considerably less, and in these days of pressure of work under abnormal conditions the use of the higher grade fertiliser means a distinct saving.

The percentages of total phosphate included in terms of tribasic phosphate of lime vary from 12 to 42, while the price also varies from 6os. per ton to 100s. As this should be a valuable for grass on all types of soil, I strongly advise farmers to order early to ensure delivery by the end of October at the latest.

THE HARVEST OUTLOOK

Never have I seen the Wheat crop more promising than now; the difficulty is to find an inferior crop. The dry weather of spring and early summer suited the growth of this cereal where it was sown in good time, and the rains have come at an opportune moment to aid the swelling of the grain. The straw is tall and stiff and the ears well developed. My only fear is that with much wind and rains the crop may be "laid," and this militates against good quality corn and a rapid harvest, as there are certain to be many "grown" corns owing to the ears lodging on the soil, which quickly induces premature germination while in the ear.

Oats at one time promised to be a poor crop owing to drought, but where the seed was sown early in March, or earlier, and the land in good condition, growth of late has been surprisingly good, and the bulk of this crop promises almost an average yield; on newly ploughed grass land there are many excellent crops of Oats. On a 15 acre plot of White Hero Oats, following Wheat, I have promise of an abundant crop; the straw is tall, standing quite erect with large ears, betokening a heavy crop, and promising well for the future of this variety, which was raised by Messrs. Garton, Warrington.

Barley in many fields has suffered much from drought and late sowing. The straw is short and unpromising, while in other fields under better cultural conditions growth has been so vigorous that crops are already "laid." At one time, in South Hants, the harvest promised to be early, but the recent spell of cold weather has altered the outlook in that direction.

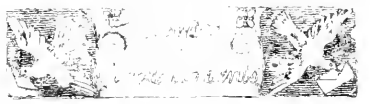
Malpensor

CONDITION OF THE CROPS.

Summarising the returns given in the monthly report of the Crop Reporters of the Board of Agriculture, and expressing an average crop by 100, the condition of the crops on July 1 indicated probable yields per acre which may be denoted by the following percentages:—Wheat, 105; Barley, 93; Oats, 95; Beans, 101; Peas, 99; Potatos, 100; Mangolds, 95; seeds hay, 99; meadow hay, 97; Hops, 70

Obituary.

MALCOLM TAYLOR MCINTYRE Mr. Malcolm Taylor McIntyre died at College Hills, Honolulu, Hawaii, on Wednesday, May 29 last. He was farm steward and manager, for the past eleven years, of the farm stock, Sugar Cane and Pineapple plantations at College Hills, the estate of the Hon. S. M. Damon, Moanalua, Honolulu. Mr. McIntyre was for many years gardener to Sir Charles Tennant "The Glen," Innerleithen, and while in the service of Sir Charles he was awarded the Nicl Prize for his exceptional abilities as a cultivator. Mr McIntyre was a highly skilled plantsman and fruit grower, and one of the few men who excel in all departments of gardening. While at "The Glen" he won many 1st prizes at exhibitions for splendidly grown Orchids. His son Donald was appointed gardener to the Hon. S. M. Damon at Moanalua, Honolulu, Hawaii, and a few years afterwards the father succeeded the son in the position. The pleasure grounds at Moanalua are extensive and very beautiful, and contain a large number of the finest flowering shrubs flourishing in the Hawaiian Islands, also large numbers of ornamental foliage plants and Tree Ferns. Mr. Damon is an ardent horticulturist. Orchids are, perhaps, his greatest favourites, and Mr. McIntyre was able, from his special knowledge of the culture and management of these plants, to aid Mr. Damon in forming a good collection. The climate of Honolulu is specially favourable to Orchids, and more particularly the Brazilian and South American kinds; Laelias and Cattleyas grow and flower profusely there, and Mr McIntyre had great success with the Torres Straits Dendrobiums, especially D. Phalaenopsis var. Schröderianum.



BLANKET WEED IN A LAKE: *J. E.* The waterweed which is choking up the lake is a species of Spirogyra; it is commonly known as the Blanket Weed. This and similar weeds may be destroyed with copper sulphate. Multiply the average length, width, and depth of the sheet of water; this will give, approximately, the content in cubic feet. Multiply the number of cubic feet by 6½, and the result will show the number of gallons. For every 100 000 gallons of water take 1 lb. of copper sulphate, break it finely, and place it in a bag of loose texture. Draw the bag through the water, forwards and backwards, in parallel lines 10 feet to 20 feet apart. The sulphate will dissolve in the water and kill the weeds. If proper proportions are used, and the work is done properly, the copper sulphate is not likely to harm fish.

CELERY LEAF BLIGHT: *D. S.* It is advisable to spray Celery plants now as a preventive against Leaf Blight. This disease is often confused with that caused by the leaf mining maggot of the Celery fly, but may be distinguished by the presence of innumerable minute black specks on the leaves and stems, and by the absence of the white spots with the maggots between the upper and lower skins of the leaf. Leaf Blight is caused by a fungus, and the black specks alluded to contain numbers of spores which spread the disease. The foliage suffers severely, and in bad attacks the whole plants are dwarfed and rendered useless. To protect the plants they should be sprayed with Burgundy mixture. This may be done at the same time the Potatos are being sprayed. If one or two further sprayings are given at intervals of about three weeks the plants should be able successfully to resist an attack.

COLOURED LATHYRUS FLOWERS AMONG CULINARY PEAS: *T. S.* The "rogues" among the Gradus culinary Peas appear to be specimens of Lathyrus tingitanus, a hardy annual species native of Tangier. It is a very old garden plant, though not commonly grown; how it came to be mixed with the culinary Pea we cannot explain, but it is just possible some plants of the species have been cultivated locally and the seeds distributed by birds or other agency.

DAMAGE TO DOUBLE PRIMULAS: *E. B.* We cannot say what has caused the damage, but it is obvious that something has eaten into, and in some cases through, the neck or "collar" of the plants, and decay has followed. It is probable that grubs of some kind have been imported with the leaf mould used in the potting compost; it is always a good plan to sterilise leaf mould before using it.

EFFECT OF CYANIDING ON FRUITS: *C.* Although cyaniding, if properly carried out, will kill insect pests in glass houses, it has no effect upon the fruits, nor are such fruits rendered poisonous. Hydrocyanic gas is generated as soon as the cyanide comes into contact with the sulphuric acid and water, therefore the "trapping" arrangements should be worked from the outside of the house by means of a cord or wire passed through the keyhole or similar small opening. As the gas is highly poisonous it is dangerous for anyone to remain in the house after the cyanide is placed in the sulphuric acid.

ESCALLONIA LANGLEYENSIS: *T. J. H.* The plant of Escallonia langleyensis being crowded with shoots, these should be thinned now by cutting away the weaker growths. This will allow light and air to enter the tree freely and assist in the thorough ripening of the wood. Next April cut the shoots back to within one or two eyes of the base, and adopt this system of pruning annually. Escallonias flower on the shoots of the current year, so there is no danger of the plants not flowering if the pruning is done in the spring.

FAILURE WITH POTATOS: *H. B.* The failure is due to over ripened "seed" tubers; such setts do not rot when planted, and unless the seed tuber decays the resulting crop is invariably very poor. Home-saved setts should be selected from a crop produced by Scotch or Irish seed, and it is a good plan to choose the setts from those plants which keep their foliage green for the longest period.

FRENCH HORTICULTURAL JOURNAL: *D. J. H.* A French publication suitable for your purpose is the *Revue Horticole*, this is issued bi-monthly, and published by M. Daniens, 26, Rue Jacob, Paris.

GARDENERS AND WAR SERVICE: *A. W.* Your best course will be to apply to the War Agricultural Executive Committee for a voucher; state your case as clearly and fully as possible, in writing, and show exactly what you are doing in the direction of food production, the area under cultivation, and the assistance you receive.

MILDEW ON GRAPES: *M. S.* The Grapes received give ample evidence of a bad attack of mildew. Dust the affected bunches and foliage with flowers of sulphur, and maintain a buoyant atmosphere in the vinery by the use of a little fire-heat and careful ventilation. As your vinery is near the river, and in consequence the Grapes very liable to attacks of mildew, there is the greater need of fire-heat, coupled with judicious ventilation, to dispel superfluous atmospheric moisture and prevent cold draughts.

NAMES OF PLANTS: *J. W.* 1, Lonicera Periclymenum var. belgica, known in gardens as the Dutch Honeysuckle; 2, Indigofera Gerardiana. *B. L.* Probably Hydrangea hortensis var Mariesii.—*J. J. Waters.* Allium Scorodoprasum, commonly known as Rocambole, or Sand Leek. The plant is grown for the use of its bulbs, and is cultivated in a somewhat similar manner to Garlic.

PLANTING FRUIT TREES: *W. S.* The general scheme appears to be good, but the cordon trees for the pergola should be planted not closer than 18 inches apart. Plums do not lend themselves to the cordon method of training as do Apples and Pears. A few bush Apples widely planted among the Gooseberries and Currants will add to the value of the plantation, especially if late varieties are chosen.

ROOKS AND WALNUTS: *T. E.* It is not an easy matter to prevent rooks from stealing Walnuts unless someone is always about with a gun. One of the mechanical bird scarers which produce a loud, intermittent noise and are worked by wind, would probably keep the birds away; they cost about 15s. or 20s. each.

SPOT AND MILDEW ON GRAPES: *A. B. C.* The Grapes are suffering from a bad attack of mildew and the disease known as "spot" (Gloeosporium ampelophagum). See also reply to *H. G.*, p. 20.

WHITE FLY ON TOMATOS: *A.* The White Fly or Aleyrodes vaporariorum, and the Tomato house may be cleared of the pest by fumigating with hydrocyanide. In a note by Mr. G. H. Head in the issue for March 16, 1918, p. 117, a method of destroying this pest by cyaniding was described in detail.

YELLOW LEAVES ON CUCUMBERS: *A. W.* Although the Cucumber leaves are not diseased they have a very unhealthy appearance. The yellowing is due, probably, to uncongenial conditions at the roots, such as cold and wet soil. Heavy soil, excess of moisture, and lack of drainage may have combined to prevent healthy root action, with a corresponding effect upon the foliage.

THE MULBERRY IN LONDON.

MULBERRY gardens were formed both at St. James's Park and Queen's (or Park) in 1609 by order of James I. Of the single remaining tree on each of these sites though in one case labelled as having been planted at the instigation of that monarch—is evidently of no great antiquity, and, judged by comparison, can hardly be considered as either the largest or oldest of those at present growing within the metropolitan area. With the exception of the trees at Charlton, those in Cassiobl and Ruskin Parks and the grand old specimen in front of Mid-may Conference Hall (see fig. 16), it is probable that many of the Mulberries which were planted at the command of that monarch are now in existence in London.

By careful comparison of size with that of existing specimens whose ages are known, and taking into consideration the general condition of the tree and the quality of the soil in which it is growing, it is quite possible to arrive at a fairly accurate estimate of the age. Tradition and a label attached point to one of the old, shattered trees at Charlton Park, Blackheath, the residence of Sir Spencer Maryon-Wilson, as the first Mulberry brought to England, and certainly when the above points of comparison are taken into account there would appear to be substantial grounds for the statement. The largest tree, which has suffered much from storms, having lost the upper part of the stem in consequence, is still of giant proportions, the trunk girthing 8 feet 7 inches at 3 feet from the ground level, the greatest height being 20 feet and the diameter of branch spread 24 feet. Though the trunk is old and shattered, the globose head of foliage is perfectly healthy, and fruit is produced in abundance; though the tree is reputed to be three centuries old, there is no reason why it should not survive for another hundred years at least. The Mildmay Mulberry, though smaller in girth of stem, is, however, the largest both in height and branch-spread, and is in a wonderfully healthy state of preservation, which is, no doubt, largely owing to the position it occupies, as also to soil conditions and immunity from accident or disease, for there is not a dead or dying branch to be seen, while the trunk is perfect in every respect. This tree is 35 feet in height, the stem 6 feet 4 inches in girth a yard above the ground level, while the diameter of branch-spread is probably unique for a Mulberry, being no less than 60 feet. There are good specimens of the Mulberry in Ruskin and Vauxhall Parks, the stem girths being respectively 6 feet 7 inches and 6 feet 5 inches. Two others of still larger size, but difficult to measure owing to their recumbent habit of growth, are growing in Clissold Park and Waterlow Park, the stem girths being approximately 7 feet.

In 1609 James I. passed his famous edict for introducing the culture of the silkworm into this country, and, judging from the expenses of his household, not only planted Mulberries largely himself, but supplied trees to others at the low price of two farthings each. It is well known that the rearing of silkworms and spinning of silk was an industry at several parts of London, notably about Spitalfields, around Arbor Square, by the Commercial Road, and at Maida Vale, at all of which places remains of Mulberry trees are still to be found growing. Even at the present time lessons on silk-spinning are given in the pretty little Arbor Square gardens by a retired naval officer to the numerous children who congregate during play hours in this "little-known East-End retreat. Two healthy specimens of the Mulberry may be seen in these gardens, and several of much larger size were uprooted when a building close at hand was erected. It is

FIG. 16.—MULBERRY TREE IN MILDMAY PARK, LONDON.

but a few years since a fine old tree was blown down in Bunhill Fields burial ground, and another giant tree of the same kind stood in the Quaker's burial ground in Wheeler Street, Spitalfields, until a few years ago. Old gardens in the Maida Vale district contain some large specimens of the Mulberry.—*A. D. Webster.*

NOTICES OF BOOKS.

THE GENUS VIGUIERA.*

THE genus Viguiera is hardly known in cultivation at present, yet the genus comprises some 150 species, and it is very closely allied to Helianthus, now so fully represented in gardens, large and small. Indeed, the few species of Viguiera on record as having been in cultivation are mostly under Helianthus. For example, V. linearis as H. linearis (*Botanical Register*, plate 523). But it would puzzle a trained botanist to decide to which genus some of the species belong, as the main differential characters are furnished by the pappus. As limited by Mr. Blake, Viguiera is restricted to America, ranging from California, Nevada, Arizona, New Mexico and Texas through Mexico, the West Indies, Brazil and Colombia to Argentina and Chili, chiefly in temperate and sub-tropical regions. Less than half a dozen species occur north of Mexico. On the contrary, the distribution of the 80, or there about, species of Helianthus is very different, some 65 inhabiting the United States and Canada, with a small number in North Mexico, and a small isolated group in the mountains of Ecuador and Peru. The genus Viguiera yields a substance of economic importance.

* *A Revision of the Genus Viguiera.* By S. F. Blake. A thesis presented in partial fulfilment of the requirements for the degree of Doctor of Philosophy in Harvard University. Contributions from the Gray Herbarium of Harvard University. New series, No. LIV.; pp. 20; with three plates. (Cambridge, Mass., U.S.A., June, 1918.)

THE FLORA OF FORMOSA.

DR. BUNZO HAYATA'S *Icones Plantarum Formosanarum* has reached its seventh volume. This volume deals with species of various families, from the Berberidaceæ down to the Solanaceæ, and the Gramineæ occupy more than half of the volume. These number nearly 200 species, belonging to 70 genera, of which 44 are represented by only one species each. There is an unexpectedly large development of the Bambuseæ, twenty-two species of this tribe being recorded, the genera represented being Arundinaria, Phyllostachys, Bambusa, Dendrocalamus and Schizostachyum. One new genus of grasses is described under the name of Pseudopiptatherum. The volume also contains a synopsis of the Rubi of the island, numbering 26 species, which are illustrated by figures of their leaves. The plates, of which there are forty-one, represent nothing specially striking from a horticultural standpoint. Dr. Hayata's present estimate of the vascular plants of Formosa is 2,759 species belonging to 1,173 genera and 161 families.—*W. B. H.*

ORCHID NOTES AND GLEANINGS.

CATTLEYA SYBIL ROSEBANK VARIETY.

A FLOWER of the fine variety of the favourite cross between *C. Dowiana aurea* and *C. Iris-dawsoni* (bicolor × Eldorado) has been sent by J. Ansaldo, Esq., Rosebank, Mumbles, with whom it has recently bloomed. In size it equals Cattleya Eldorado, the scent of which is also present. The lip, with its inch-long isthmus, discloses the fact that *C. bicolor*, the original species, as is commonly the case, is the dominating parent. The sepals and petals are cream colour, delicately tinged and veined with light mauve; the showy labellum has the front side lobes pale yellow veined inside with rose; the median isthmus being bright yellow and the expanded front lobe ruby red with a delicate violet shade.

REPORT ON THE CONDITION OF THE OUT-DOOR FRUIT CROPS.

[FROM OUR OWN CORRESPONDENTS.]

THE WORDS "AVERAGE," "OVER," OR "UNDER," AS THE CASE MAY BE, INDICATE THE AMOUNT OF THE CROP; AND "GOOD," "VERY GOOD," OR "BAD," DENOTE THE QUALITY.

FULLER COMMENTS WILL BE GIVEN IN THE FOLLOWING NUMBERS. SEE ALSO LEADING ARTICLE ON PAGE 45.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* EDITORS, 41, Wellington Street, Covent Garden, London. *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 62.19.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, August 1, 10 a.m. Bar. 30; temp. 68°. Weather—Sunshine.

Failure of the Fruit Crops.

The tabulated returns on the condition of the hardy fruit crops furnished by correspondents in different parts of Great Britain and Ireland, which we publish in the present issue, show that the outdoor fruit crops of 1918 are amongst the worst on record.

That the fruit yields this season were bad was already common knowledge, but we doubt if anyone expected such dismal failures as our figures show. The deficiency is especially serious in the case of the principal crops—Apples, Pears, Plums, and Cherries.

Concerning Apples, there are 234 returns, and of these no fewer than 206 of our correspondents report a crop under the average, whilst only 6 have a yield of more than the average. Pears are even worse, for of a total of 229 returns, 222 give under crops, with only 2 over and 5 an average yield. The Plum crop is also an exceptionally poor one, for whilst 21 report a crop of average quantity, no fewer than 201 correspondents record a yield below the normal. Cherries and Apricots are almost as unsatisfactory: of 219 returns in the table for Cherries, it will be seen that 150 show a deficiency; whilst of Apricots, out of a total of 150 returns there are 80 failures.

Peaches and Nectarines, which are not of such utilitarian value as the other fruits mentioned, show a return almost equally divided between under and average crops, so that with a balance of 15 over there is not such great cause for disappointment in respect to these. Small fruits, amongst which are included Currants, Raspberries, and Gooseberries, are more satisfactory, and those who study our tables carefully year after year will know that this section of the hardy fruit crops is the most reliable of all.

But even with these there is nothing exceptional to report, for of a total of 234 returns 45 under crops are given; whilst of Strawberries the deficiency is even greater, more than a third of the number of correspondents—84 out of 232—having an under crop of these fruits. The returns with respect to Nuts are almost equally balanced between good and bad, there being 54 returns of average yield and 61 below.

Most of our correspondents have contributed these reports for several years, and have been accustomed to make accurate observations over a number of seasons, so that their statements may be taken as an accurate summary of the conditions. The present scarcity and general high prices of all kinds of fruits have caused the public to realise, as never before, the importance of the home fruit crops. In normal times a deficiency causes nothing more serious than a rise in prices, but at the present time fruits are practically unobtainable by those who do not cultivate them, and, we fear, in many cases, even by those who do. As we may expect that imports will be restricted for some years, even though the war should cease soon, there is every reason to anticipate that home-grown fruits will be in high demand for the next season or two, and efforts should be made to increase the home yield. Certain kinds of fruits give speedy returns, whilst even Apples, Pears, and Plums may be expected to furnish moderate crops the following season if suitable trees are selected and planted early in the autumn, to become well established by the time winter arrives. The Raspberry is, perhaps, the most reliable of all our common fruits for giving satisfactory returns the year after planting; and as the canes may be purchased cheaply, special plantations should be made as a war measure, and every alternate plant cut down to a foot from the ground level to supply strong suckers to enable the plants to carry on the following season, leaving the others to furnish a crop. Cottagers and allotment holders would be well advised to utilise their home gardens for these and other small fruits. If Strawberry runners are suitably prepared they will give a return when one year old; and even better for the purpose are pot plants that have been forced, provided they are given care and attention subsequently. Such bush fruits as Gooseberries and Currants are very profitable in a short period from planting, and the fullest use should also be made of these. Of all fruits few are more remunerative than the Morello Cherry, which may be described as a perpetual bearer. Even in this untoward season Morello Cherry trees have given a fair crop of extra fine fruits.

Turning to the causes that are responsible for the failure, they appear to be the exhaustion of the trees last season through bounteous cropping and the unfavourable weather of April this spring, following a March of unusual warmth. The autumn of last season was not favourable to the ripening of the wood of the current season, and it is probable that with the undue strain of prolific crops the trees were unable to form flower buds of sufficient strength to develop fruits. Several correspondents earlier in the season pointed to the deficiency of Pear bloom, some recording a total absence of flowers. Apples flowered fairly well, but the blooms lacked substance, and were unable to withstand the trying weather when they were expanded. The failure of the Plum crop is a greater mystery, for there was promise of a bountiful crop early in the season. The trees blossomed earlier than usual, favoured by a March of exceptionally warm weather, but April followed with cold nights and hot sun by day. Added to these was a cold, drying wind from the north and north-east, and the blossoms dropped wholesale, with the result that the Plum crop is one of the most unsatisfactory of all. Some are inclined to attribute the failure partly to the absence of bees, but we do not think this question of insect pollination has such a bearing on a good or bad fruit year as many believe. The wind is a greater agency in the distribution of pollen than many are disposed to believe, and there are many self-fertile varieties amongst not only Plums, but others of our hardy fruits.

The prevalence of insect pests this season is noted by several correspondents, and we fear that this is due, in a large measure, to the absence of the necessary labour for spraying.

A NEW POMOLOGICAL WORK.—The Pomological Society of France has decided to publish, in monthly instalments, the valuable descriptive work of M. DE LA BASTIE, on Pears and Apples as a supplement to the Society's Journal. M. DE LA BASTIE was for many years President of the Pomological Society, and his collection of fruits at Belvey was well known to all who followed French Pomology. His valuable notes were given at his death to the Society, and will now become available for its members. The subscription for the Journal and the special supplement will be 12 francs. Those interested should write to the President of the Society, 9, Rue Constantine, Lyon, France.

CURE FOR THE POISONOUS EFFECTS OF THE POISON IVY.—Some people can handle Rhus Toxicodendron, the Poison Ivy, with impunity, but others suffer from severe skin irritation if touched by a leaf. To those who are not immune it will be of interest to learn, on the authority of *The Florists' Exchange*, that a cure may be effected by applying carbolic acid (95 per cent.) and iodine, mixed in equal parts, to the affected part, after outlining this area with oil. This cure is said to take effect in three days, but it is not recommended for use where the poisoned portion is very large or where there are numerous poisoned areas on the body. When the itching so characteristic of this poisoning is intolerable, relief may be obtained by the application of water just as hot as the patient can bear it. If very hot water can be borne the relief from pain will continue for at least four hours. Moreover, the hot water absorbs some of the poison, thus preventing the spread of the trouble and hastening the cure.

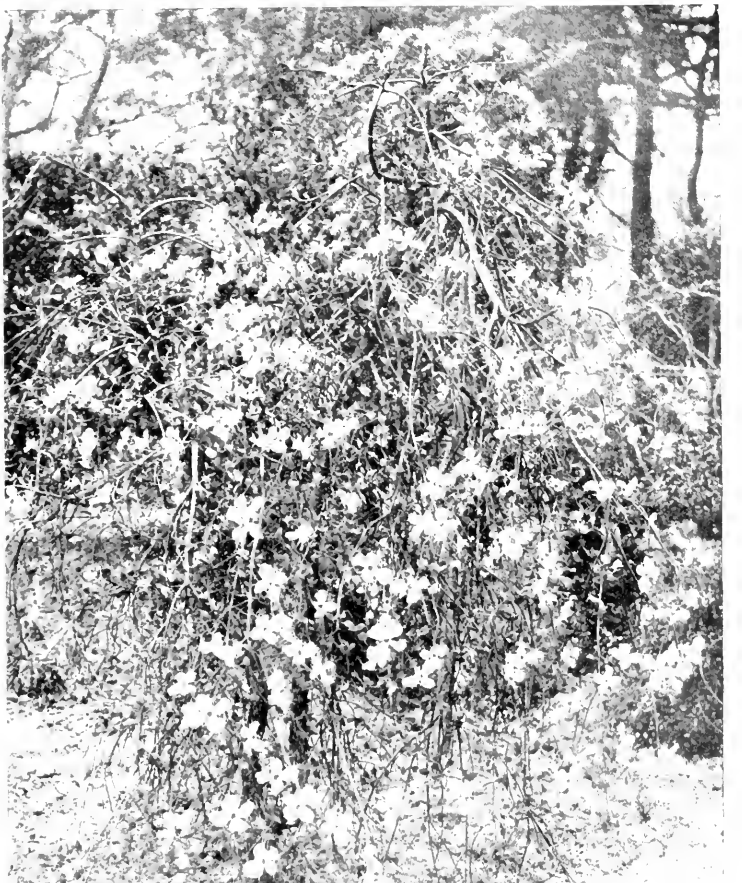
Certificates of Merit for Food Production.—Through the agency of the County and District Horticultural Committees the Horticultural Section of the Food Production Department is prepared to grant certificates to local Horticultural Societies and Allotment Holders' Associations, such certificates to be awarded for special skill in the cultivation of allotments and gardens, and for meritorious collections and single dishes of fruits and vegetables. Secretaries of local societies should apply to their district Horticultural Committees for these certificates.

New Director-General of Food Production.—The President of the Board of Agriculture and Fisheries has appointed Sir Charles W. Fielding, K.B.E., Director General of Food Production, in succession to Lord Lee of Fareham. Sir Charles Fielding has for years past taken an active part in the movement for the increased home production of food. He was a member of the Committee appointed by Lord Selborne to consider and report what steps should be taken by legislation or otherwise for the sole purpose of maintaining, and, if possible, increasing the present production of food in England and Wales, on the assumption that the war may be prolonged beyond the harvest of 1919. Sir Charles, who is an engineer by profession, has had charge, under the Ministry of Munitions, of the supplies of coal, the fixing for the moment of the price of explosives, and the supplies of the Army. He is now Chairman of the Materials and Machinery Committee of the Ministry.

Shading for Glasshouses. A first-rate whitewash which does not peel may be made by dissolving 2 lbs. of size in 7 gallons of water, and when all is dissolved adding to it 1 lb. of bichromate of potash, also dissolved in a pint of hot water. Stir the mixture well, and then add sufficient whiting to bring it up to the consistency of thick cream. Apply with a brush in the ordinary manner as quickly as possible. The mixture dries on in a very short time, and by the action of light becomes converted into a perfectly insoluble compound, a substance which does not wash off even with hot water, and at the same time does not give rise to moss growth, as whitewash made with size often does. It may be coloured to any desired shade by the use of a trace of any aniline dye. Another useful shading material is made as follows. Take one pound of flour, and keep just covered by the water while making. Strain through coarse cloth. Add 4 quarts of fine salt dissolved in warm water, 1 lb. of ricemeal boiled in water to a thin paste, ½ lb. of whiting, and ½ lb. of zinc dissolved in warm water. Mix all thoroughly and allow the mixture to stand covered for two or three days, stirring occasionally. Heat the whole before using.—*Queensland Agricultural Journal.*

Scarcity of Castor Oil. The fact that castor oil does not freeze under low temperatures has been turned to good account in the aeroplane industry, which had need of a lubricant that would not solidify in the low temperature of high altitudes. As the demand has increased with the great expansion of the aeroplane industry, the oil has become very scarce and dear for other purposes. Hitherto India has been the chief source of supply, and has exported about two million gallons of oil annually. In the Western United States 100,000 odd tons of acres have been placed under crops of Ricinus, for oil production, while in Jamaica and other West Indian islands the possibilities of castor oil production have been brought to the notice of cultivators. At present prices the crop may prove a paying one in districts where, under pre-war conditions, it would have been an economic failure. It must be remembered that where the oil is extracted locally the residue may be of value as a fertiliser.

Cornus florida pendula.—Although this beautiful small tree or shrub cannot on the whole be described as an unqualified success in all parts of this country, the illustration of the plant in fig. 17 shows that there are places where it thrives exceedingly well. In several Surrey and Sussex gardens, especially where the situation is somewhat elevated, the cultivation of Cornus florida and its varieties gives no difficulty. We know from the way it succeeds in the Eastern states of North America, even as far to the north as Boston, Mass., that the tree is very hardy, but there the division between winter and spring is scarcely defined. In many gardens in Britain this Cornus is excited into growth too early, and the crop of flowers is ruined by frosts that occur after. A position sheltered from the north and east is no doubt best suited for it, other trees may be fairly excluded from the sun. The late Mr. Chambers, of Haverstock Hill, had a specimen of this Cornus florida pendula which was about 30 feet above sea level, and he used to recommend for this Cornus cool, damp situation exposed to full sunshine. Cornus florida is a native of the Eastern United States from Massachusetts to the extreme south. It reaches even the mountains of Northern Mexico. According to Prof. Sargent, it is sometimes in this country 40 feet high. With us it rarely exceeds more than 15 feet in height. What is commonly termed the "flower" is really a coloured involucre of four bracts that surrounds the small and obscure true flowers—plainly seen in the illustration. The "flower" is 3 to 4 inches across, white in the typical form and in the pendulous variety illustrated, but bright rosy red in the var. rubra. When seen at their best, which is in late May, they are two more beautiful shrubs than these. Two other species with similarly showy involucres are grown in this country: C. Nuttallii, from the Pacific Coast, with bracts even larger than those of C. florida, and creamy white flowers; and C. Kousa, from Japan, with narrower bracts, flowering in July (both these seem to be of a hardier character than florida;



(Photograph by E. J. Wallis.

Fig. 17.—CORNUS FLORIDA PENDULA.

New Secretary of the Horticultural Club.—At the committee meeting of the Horticultural Club, held on Tuesday, July 30, Mr. G. F. Tinley, Managing Editor of *The Gardeners' Chronicle*, was appointed Hon. Sec. to the Club, in succession to the late Mr. B. Hooper Pearson, who had held the office since 1911.

ON INCREASED FOOD PRODUCTION.

WINTER GREENS.

Kales, Savoys, Coleworts, and other winter and spring greenstuffs should be planted now on ground rendered vacant by the removal of early Potatos and Peas and also where there is sufficient room between growing crops of Potatos, Peas and Beans. If rows of Peas have been grown 3 or 10 feet apart, and catch-crops of Turnips, Lettuce, and Early Potatos grown between them, these will be ideal positions for Winter Greens, as the partial shade provided by the Peas will protect the newly planted crops from hot sunshine. A space of 2 feet between each plant should be allowed, and 2 feet 6 inches between the rows. Plant firmly and deeply—put in the plants up to the seed-leaf—and leave a slight depression in the ground to secure full advantage from watering.

Clear away the surrounding crops as soon as they are finished, and hoe the ground thoroughly. As the plants gain size and strength they should be earthed up in the same manner as Potatos, and some of the taller-growing Kales must be staked and tied to prevent damage from wind storms. This precaution not only adds to their good appearance but increases the yield. If plenty of room is allowed the plants will make firm growth, which enables them to stand severe weather during the winter. Scotch Kales should be given the best and most sheltered positions, as they are taller growers than the other sorts. The Russian and Cottager's Kales and Purple sprouting Broccoli are very hardy, especially the Kales, and these may be planted in the less favourable places. Plant Savoys by themselves, as, by reason of their spreading habit of growth, they are not suitable for planting between other crops. Dwarf Green Curled and Early Ulm are excellent varieties for autumn use, and Large Green and Ormskirk for later supplies. Cartercome, a new variety, I have grown for two seasons, and it is excellent, the flavour being all that could be desired. Another good vegetable for winter use is Christmas Drumhead Cabbage. Hardy Green or Rosette Colewort are very hardy. They often prove most useful as a catch crop, and no amount of frost seems to damage them.

All the varieties and kinds of Winter Greens I have mentioned should be well earthed up before the approach of hard weather, as this protects the stems from frost and keeps them steady during rough weather. It is a mistake to plant too early, as this induces excessive growth, which may not stand severe weather. Strong, medium-sized plants will stand extremes of weather much better than large, overgrown specimens. *R. W. Thatcher, Carlton Park Gardens, Market Harborough.*

PEAS AND DRY WEATHER.

Early Pea crops have been of short duration on our dry Surrey soil, but this is not due entirely to the drought. There was a time in early June when the cold nights retarded growth. The night of June 25 was colder by 11 degrees than the night of January 25, consequently there was a severe check. We gathered pods of World's Record on June 21, a week later than last year. This variety ripens and comes to maturity faster than any other Pea I know. Little Marvel and Pioneer, sown in pots, grew well until the exceptionally cold nights came when they refused to move; these two varieties do well on light soils.

Reading Giant and Early Morn have been very good, and so has Imperial Dwarf, a fine, strong-growing Pea with large and well-filled pods. International has been splendid. Harvestman is another fine Pea. Alderman and Duke of Albany promise well, and have withstood the drought splendidly. Autocrat is also looking remarkably well. These three last are in rows about 120 feet long and about 6 yards apart, with Potatos partly shading their roots on either side, and on newly trenched ground.

The later-sown Peas germinated badly, but since the rain came they have improved, and now look extremely well. I have found this season that unsupported dwarf Peas were better in every way than those supported by sticks; I believe the haulm shaded the roots and enabled the plants to withstand the drought better than those which were staked. I have gathered good dishes of Michaelmas and Late Queen Peas on Lord Mayor's Day, but a genial season is needed to procure good Peas at that late date. *W. A Cook, Abbots Wood, Godalming.*

HOME CORRESPONDENCE.

The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Apples at Wisley.—It is interesting to know that Apples are not a failure everywhere this year. Trees in the collection on the high ground above the Laboratory in the gardens of the Royal Horticultural Society at Wisley are laden with fruit. The trees have been saved from the winter moth by grease banding and by spraying with arsenate of lead. At the time of my visit the ground was very hard, as the cultivator had not been at work for want of labour, and the bush trees were casting quantities of fruit, which really requires thinning. Irish Peach and Cornish Gilliflower are fruiting on the tips of the shoots as usual. The former is notable for its high colour at present, though that is scanty at maturity; and much the same may be said of Cellini. Fruits of Colonel Vaughan are almost green, though they develop a deep red colour in autumn. True to its character, Lane's Prince Albert squats right to the ground, though grown as a bush. Other varieties also fruiting heavily are Frogmore Prolific, Bramley's Seedling, Duchess's Favourite, Duchess of Oldenburg, King of the Pippins, Golden Spire, Ecklinville Seedling, Lady Sudeley, Dumelow and many others. Cox's Orange Pippin and King of Tompkins County are good, the latter having large fruits, evenly distributed over the tree. *J. F.*

Fruit for a Royal Banquet in 1607.—My sons, who are Freemen of the Merchant Taylors' Company, were the cause of my recently acquiring a bulky volume entitled *Memorials of the Guild of Merchant Taylors, etc.* In it are the accounts in detail of the cost of a banquet given by the Company to King James I. and Prince Henry, in the year 1607. The items occupy about 19 pages, and comprise everything in connection with the feast: fish, eggs, fuel, linen, beer, butter, bread, wine, grocery, fruit, etc. It struck me that some of the readers of the *Gardeners' Chronicle* who are of an antiquarian turn of mind might be interested in the names and prices of the fruit that was then placed upon the table. They are as follow:—For 3 syves of Cherries and 20 lbs. more at 5d., £1 15s. 6d. For Strawberies for the King's cookes, 2s. For 3 gallons of Gooseberies, 3s. For a gallon and half of Raspices, 5s. For certen seedes for the cookes, 1s 10d. For 2 hamper of Quodlings, 12s. For a hamper of Pyppyns, 6s. For Goosecheries, Peaches, and Cheries, wth. portage, 7s. For greene fruite, Peares, Apples, and Damsyns, £1 4s. 6d. For fower score greate Lemans at 8d., £2 13s. 4d. For fower score midle Lemans at 4d., £1 6s. 8d. For 150 grete Orenges at 4d. the peece, £2 8s. For 250 midle Orenges at 1d. the peece, £1. For 60 lbs. of Potatoes at 10d. the pounde, £2 10s. For 136 Quinces at 4d. the peece, £2 3s. For 40 largess Quinces to Mr. Wallis at 6d., £1. For flyfty large Quinces to him at 6d., £1 5s. For 10 dozen of Artechoks at 5s. the dozen, £2 10s. For 6 gallons of Gooseberies at 16d. the gallon, 8s. For 3 quarts of Redd Currens, 3s. For Parsly 6s., Lettis 5s., and Purslane, 2s., 13s. For Spynnage 3s., smale sallett 2s. 6d., 5s. 6d. For corne sallett 2s., Tarragon and Rockett 12d., 3s. For flowers of all sorts 6s., Rosemary and Bayes, 5s., 11s. For Burredge and Burnet 12d., Carrets and Turneps 3s., 4s. For sweetherbes of all sorts 3s., Onyons and herbs 12d., 4s. For Sorrell and Fennell 18d., for Reddishes 6d., 2s. For hartechoke suckers, 1s. Further on there are lists of other fruits, fresh and candied, such as Plums of Arabia, Venis Dat Plums, Pruons of Genoa, greene Dates, dried Pedrogots, Plums of Marcelis, Peares of Roun, Pruons Brembe, Apples of Damasco, Frayses of Genoa, Madere Citrons, Suckett Peares, Canded Cioues, Canded Eringas, Canded Gilliflowers, Vagasses of Genoa, Dry Plumes, Pruons of Brunello, etc., etc. The feast, with its incidental expenditure, appears to have cost £1,061 5s. 1d.—a considerable sum considering the value of money over three centuries ago. *C. H. P.*

American Blight.—If his short list of varieties of Apples that are liable to attacks of woolly aphis is complete, then Mr. Brotherston must be more fortunate than most of us, for I am sure the list could be greatly extended by a general canvass. The variety which, in my experience, suffers most, is Cox's Orange Pippin, and I have seen American blight on many other sorts. A week or two ago I saw a young standard John Downie Crab literally smothered with the pest. The woolly aphides were even festooned around this season's shoots. This points to a decided contradiction of the widely-spread impression that the blight is purely a wound parasite, and I am sure many other instances of attacks on young growth could be cited. The Crab is growing in a shrubbery a goodly distance from any fruit trees, so the conclusion I drew was that the aphis came with the tree when it was purchased three years ago. In its out-of-the-way position the insects increased unnoticed, and in all probability many other Crabs are infected. That valuable work, *The Book of Garden Pests*, mentions American blight as one of the insect enemies of the Pear; no particular varieties are named, and it is probable that, as with Apples, it is indifferent to such trifles. *A. C. Bartlett.*

Fuel for Glasshouses.—The leading article in your issue for July 6 was most timely and to the point, and will afford valuable assistance to horticulturists both in private establishments and public gardens. Valuable collections of plants, often the result of many decades of untiring effort, should be saved from destruction. It is possible to reduce the number of these in nearly every instance and devote the room, as you state, to food production. No glass structure of any kind whatever should be allowed to remain empty. Two crops, e.g., Potatos and Tomatos, can often be grown in the same season in houses that are but moderately heated. The statement that a smaller amount of firing will in the end be beneficial to fruit trees in houses, with, as a matter of course, less forcing, is to the point. At Gunnersbury House Gardens we have practically ceased the early forcing of either vines, Figs, or stone fruits of any kind. In consequence of the rest the vines have greatly improved in vigour, and our pot fruit trees never cropped better, on the whole, than this year. It is most timely advice to have the hot-water installations overhauled and the furnaces, etc., put into proper order. This attention in itself will result in a saving of fuel. In times long past I had the management of the stokehole, and was expected to keep up the required temperatures with wet, sappy roots, slack coal, and cinders: anthracite coal and ordinary coal were only provided in the coldest of weather. Waste results in not keeping the fires well damped down and checked on warm days. By a careful use of rough wood a considerable saving of other fuel may be effected. I have used timber, and none too dry either, in conjunction with the refuse from the cinder heap when flues were still in use in old-fashioned greenhouses, and we grew good specimen plants. There is not any saving whatever, but the reverse, in attempting to make one boiler do the work of two. Two medium-sized boilers are infinitely better in one stokehole than one large one, and it is always best to have boilers set in duplicate. If I run short of fuel during this coming winter I have a supply of Elm logs blown from our trees during the severe storm early in 1916. When the weather is not fit for outside work it will be possible to prepare some of this timber for the stokehole during the late autumn. *Jas. Hudson, Gunnersbury House Gardens, Acton.*

The Week's Work.

THE KITCHEN GARDEN.

By F. Jordan, Gardener to Lieut.-Col. Spender Clay, M.P., Ford Manor, Lingfield, Surrey

Potatos.—A long spell of wet, close weather at this time of the year is invariably conducive to the spread of the late blight disease. Last year in some gardens whole breadths of Potatos were diseased as early as the middle of July up to the present I have found no disease in our comparatively large, open quarters, but increased warmth will be favourable to the spread of the disease during the next few days. Let the weather be what it may, the more delicate early varieties are almost certain to be affected soon. If the foliage is only slightly diseased and but few of the uppermost tubers affected, then all may be lifted and stored with advantage. When a diseased crop is lifted and stored early, many tubers slightly affected escape notice, and unless the crop is most carefully examined, many decaying tubers will be found after the heap has been stored for some time. Potatos that are still growing vigorously should be left undisturbed for some time longer, as the only cause for anxiety now is the unsettled condition of the weather. All diseased foliage should at once be collected and burnt.

Ridge Cucumbers. The hot, sunny weather of June favoured a strong, early growth of out-of-doors Cucumbers, which, under various systems of culture, are especially productive. It is very unwise to leave a few fruits to attain a large size, as these are of little value and greatly impair the fruit-bearing habit of the plants. Keep the plants well supplied with water, and give them an occasional application of liquid manure.

Vegetable Marrows.—Marrow plants are producing fine crops this year, the season being warm. Marrows rooting in a mass of rich manure are growing too rapidly, and are by no means so productive as those put out on well-manured open ground or on slightly raised beds with only a limited quantity of manure. Stopping the growths in the case of buxom plants will not increase their productiveness much; they are likely to be more fruitful when the growths are allowed to ramble thinly and not trained. Large fruits are not favoured for the table, but later in the season they will be of considerable value for jam-making.

French Beans.—From a small sowing of French Beans made in a cold pit at this date last year we could pick a good dish almost every day until severe frosts occurred in the autumn. Lights should be placed over the frames when heavy rains fall in October, but they should be tilted to permit of a free circulation of air in the frame. Few other plants are more easily damaged by slight frosts or cold east winds than the French Bean. Sow a few seeds in pots towards the end of the present month, and grow the plants in cool conditions, to be brought forward under glass in pits and cleared in readiness for them.

FRUITS UNDER GLASS.

By W. J. Guise, Gardener to Mrs. Dempster, Keele Hall, Newcastle, Staffordshire

The Vinery.—No fruit improves so much by hanging as the Grape, and to keep the bunches in a fresh, plump condition the house should be freely ventilated day and night. The essential point is a cool and fairly dry atmosphere, with a continuous current of air under the bunches. This treatment not only improves the fruit, but is also necessary for the ripening of the wood, which should be brown and hard, with plump buds, before the autumn. It is advisable to maintain a little warmth in the water-pipes during cold, wet weather to prevent condensation of moisture on the berries. Examine the bunches and remove defective berries forthwith. Outside borders with soil of a retentive nature would be much better covered with galvanised iron sheets or some other suitable material to ward off heavy rains.

Muscat Vinery.—Muscat of Alexandria Grapes are colouring, and from now onwards very careful attention to details is necessary if the bunches are to finish well. Some growers entirely dispense with fire-heat at the ripening period with excellent results, but in cooler districts, or during a spell of cold, wet weather, it is advisable to employ a little artificial warmth. A few bunches of Muscats need a warm, drying temperature to finish well. If a little air is admitted by the top ventilators through the night, there will be no danger of the berries scalding. Sulphatarea should be continually kept in use, as Mus at Grapes need plenty of light and air, and the removal of many superfluous growths at one time would give a check to the Vine. Should red spider be detected take steps to exterminate the pest by spraying the rafters with clear soapy water to which a little sulphide has been added.

PLANTS UNDER GLASS.

By E. Hobbiss, Gardener to Lady Wantage, Lockinge Park, Berkshire.

Perpetual Carnations.—Young plants of Perpetual-flowering Carnations should be staked, when they need supporting, with green Bamboos. Do not crowd the young growths, and arrange the plants so that plenty of light reaches them in every part; overcrowding is one of the chief causes of "rust." Some of the younger plants will soon be well rooted and may be given a little stimulant. For the first week or two weaken soot water with about two parts of water, and this fertiliser will impart a good colour to the foliage. If the plants are under glass of the sort, store be thrown wide open at all times, and excess of heat to be avoided. Lightly fumigate the house occasionally to keep the plants free from aphis. The foliage should also be sprayed with copper sulphate about once a fortnight as a preventive of rust disease.

Coleus.—To obtain fine colour in the leaves of Coleus expose the plants fully to the sun. The house must however be carefully ventilated, or the leaves may become scorched. When the pots are full of roots do not allow them to suffer for want of moisture. Before being used in the conservatory or dwelling the plants should be gradually inured to cooler conditions, as a check caused by a sudden lowering of the temperature may cause them to lose some of their lower leaves.

Violets.—These plants should be attended to once a week for the purpose of removing runners. Keep the hoe at work between the plants, and, to promote healthy growth, give them an occasional dusting with well-seasoned soot. If there is the least evidence of red spider on the foliage an effort should be made to destroy the pest before the end of the season.

THE ORCHID HOUSES.

By J. Collier, Gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate.

Cattleya and Allied Genera.—Cattleyas, Laelias, and the numerous hybrids of these Orchids that have recently passed their flowering stage, should be kept slightly on the dry side until new top growth and new roots are produced. Also any necessary repotting must be done. For small pots. The pseudo-bulbs of many of the plants will shrivel after root disturbance, and such plants should be watched with extra care. It is best to simply spray over overhead two or three times each day, and keep their surroundings moist by frequently syringing between the pots. It is not a good practice to saturate newly potted plants with a view to inducing the pseudo-bulbs to retain their plumpness during the time the soil is wet the old roots will gradually decay, neither will the young roots thrive in a saturated material. Such Cattleyas as C. Dowiana and its variety aurea, C. Warscewiczii (syn. gigas) and its variety Sanderiana, and the hybrid Hardiana, are maturing their flowering growths and should be grown in the warmer end of the Cattleya house near the roof glass. Keep them just moist. When the flowers are over, and roots are active in the bases of the new pseudo-bulbs, the plants may be repotted. When the pseudo-bulbs are fully developed the plants should be rested, and may be suspended from the roof rafters in the coolest part of the Cattleya house. Plants that are not to be potted should be encouraged to accelerate their growth by placing them nearer the light, or where they will be exposed to the sun's rays and heat. Endeavour to prevent them from making soft new growths, and induce them to take a full rest, as many autumn flowering Cattleyas start up to make second growth immediately the first growth has reached maturity. This is frequently a cause of the plants failing to flower, or remaining soft and sappy when growth is completed.

Cattleya labiata.—The Cattleya makes its growth during summer, and flowers in autumn; already the flower buds are formed. It is only safe at this season to expose the plants elevated near the roof glass on condition that they may receive plenty of sunheat to enable them to consolidate their growths. As soon as flowers are matured, and the flowers are commencing to push through the sheaths, reduce the water supply at the roots considerably, as these plants are impatient of an over-supply of moisture at the roots at this particular season, this being often the cause of decay in the new pseudo-bulbs. A Cattleya should be kept under close observation; insect pests to which they are subject most frequently make their appearance as the new growths develop, and soon cause injury and permanent disfigurement. Small scale insects should be removed as soon as they can be detected, as minute white specks on the leaves and shoots. Thrips should be destroyed by regular syringings and vaporisings.

THE HARDY FRUIT GARDEN.

By Jas. Hudson, Head Gardener at Gunnersbury House, Acton, W.

Late-Fruiting Raspberries and Currants.—Early in August I make it a practice to examine the stock of autumn fruiting Raspberries and thin out all plants that are not showing for fruiting. When this is done a few upright stakes are fixed over the rows and Bamboo rods are tied to these horizontally. This makes a sufficiently secure support to which to tie the fruiting shoots. After this a slender piece of cane is fixed to the shoot near its apex, and it is then tied by an upward pull to the cross Bamboo. Trained in this way the weight of the fruit later does not cause the shoot to arch over. By this system all the light possible reaches the plants and it is an easy matter to see when the fruits are ripe for picking. Late Raspberries will be most useful this autumn, both for dessert and culinary use, as well as for preserving. Netting will, as a matter of course, be placed over the plants, as birds are particularly fond of the fruits. Keep the surface soil free by hoeing, and remove all late suckers. If late varieties of Red Currants are grown, the fruits are very useful in combination with late Raspberries. Both the late Red and White Currants should find a place on the dessert table this coming autumn. When bushes of these fine Currants are grown on north walls and well attended to a crop may be depended on well into the shooting season. Late Gooseberries are also most useful in the autumn for dessert. The berries keep well better perhaps, if the wall has a coping.

Late Cherries on Walls.—Where late Bigarreaus, such as Emperor Francis and Bigarreau Napoleon, succeed the fruits are most invaluable, and another good late fruiter is Géante d'Hedelfingen. These fruits do best on east walls. The Morello Cherry when thoroughly ripened is not to be despised for dessert purposes. Keep the trees securely netted and watch the fruit to see that none is decaying. Late attacks of black fly may prove troublesome but as the pest usually finds a lodgment on the ends of the shoots they may in most cases be easily removed. If this is not deemed expedient then resort to dipping the ends of the shoots in a strong insecticide.

SOCIETIES.

ROYAL HORTICULTURAL.

JULY 30.—There was no novelty of outstanding merit on this occasion; indeed, novelties and plants of special interest were few. The Floral Committee made no awards to new plants, but granted ten medals, including a Gold one to Messrs. ALEX. DICKSON AND SONS for a glorious exhibit of Roses. The Fruit and Vegetable Committee awarded two medals, and the Orchid Committee granted one First-class Certificate and two medals.

The Society's exhibition of Dry Bulbs was held on this date, and the competitors appeared to be the only enthusiastic people about, as there was a holiday-time air abroad and the day was close and sultry.

Floral Committee.

Present: Messrs. H. B. May (in the chair), E. A. Bowles, W. J. Bean, Sydney Morris, John Green, G. Reuthe, John Heal, W. A. Howe, J. F. McLeod, W. H. Page, J. T. Bennett-Poe, H. Cowley, W. B. Cranfield, J. W. Moorman, W. P. Thomson, E. F. Hazelton, Chas. Dixon, Chas. E. Pearson, Jas. Hudson, E. H. Jenkins, and George Paul.

INTERESTING PLANTS.

Messrs. BAKERS exhibited Gentiana lagodechiana, which is very like G. Freyniana, but appears to have whiter dots on the lobes of the flower, and also a more expanded bloom. Gaultheria nummularioides, a neat and pretty plant, was shown by Mr. G. REUTHE, who also exhibited Digitalis canariensis, Berberidopsis corallina, and flowering sprays of Phillyrea buxifolia and Feijoa Sellowiana. J. CHURCHER, Esq., Alverstoke, staged a little group of very elegant Gladioli, all hybrids from G. primulinus: the varieties Alice Tiplady, orange-apricot; Firefly, deep scarlet; Otranto, soft yellow; and Altair, rich salmon-pink, were especially charming. Messrs. ALEX DICKSON AND SONS' display of Roses thoroughly merited the Gold Medal awarded; the varieties "K of K," Col Oswald Fitzgerald, Mrs E. V. Haworth, Sunstar, Red letter Day, and Elizabeth Cullen, were all largely shown and effectively staged. In Mr JAMES DOUGLAS' group of Carnations the varieties Sweet Anne Page, Solfaterre, Edenside and Orange King were of outstanding merit.

GROUPS.

The following medals were awarded: *Gold* to Messrs. ALEX DICKSON AND SONS for Roses. *Silver-gilt Banksian* to Mr. L. R. RUSSELL for stove plants. *Silver Flora* to Mr. G. REUTHE for rare and interesting shrubs; to Mr. G. W. MILLER for hardy flowers. *Silver Banksian* to Messrs. J. CHEAL AND SONS for Astilbes and flowering shrubs; to Mr. JAMES DOUGLAS for border Carnations; to Messrs. H. B. MAY AND SONS for Ferns; to Rev. J. H. PEMBERTON for Roses. *Bronze Flora* to Messrs. WM. PAUL AND SON for Roses. *Bronze Banksian* to J. CHURCHER, Esq., for Gladioli.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Sir Harry J. Veitch, Messrs. Jas. O'Brien (hon. secretary), W. Bolton, R. A. Rolfe, J. Wilson Potter, Pantia Ralli, Chas. H. Curtis, J. Charlesworth, E. R. Ashton, Walter Cobb, C. J. Lucas, R. Brooman-White, Frederick J. Hanbury and S. W. Flory.

AWARDS.

FIRST CLASS CERTIFICATE.

Laelio-Cattleya Britannia majestica (L.-C. Cunhaiana alba × C. Warscewiczii From H. Bygrave) from Messrs. CHARLESWORTH AND CO., Haywards Heath.—A grand hybrid, and probably the best white-petalled Laelio-Cattleya yet raised. The plant bore a spike of four very large and handsome flowers with snow white sepals and petals. The base of the lip is white with purple lines inside; the disc chrome-yellow, the broad front lobe rich Tyrian purple with a clearly defined white margin.

PRELIMINARY COMMENDATION

Odontoglossum Marne (ardentissimum Orchid-hurst var. × Colossus), from Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells.—A superb seedling of model shape flowering for the first time. The flower, broad in all its parts, and especially in the upper sepal and lip, had a white ground, the inner two-thirds densely blotched with deep violet, the markings of the lip matching those of the sepals and petals.

GROUPS.

Messrs CHARLESWORTH AND CO. were awarded a Silver Flora Medal for an effective group in the centre of which were varieties of the white-petalled Cattleya Hesta; with these were arranged other white petalled Cattleyas and Laelio-Cattleyas, Odontoglossums, Odontiodas and Miltonia Charlesworthii.

Messrs. STUART LOW AND CO., Jarvisbrook, Sussex, were awarded a Silver Flora Medal for a group of Cattleya Warscewiczii of a very fine type, the well-grown plants bearing spikes of from five to seven blooms each; Cattleya Dowiana, other Cattleyas, and a choice selection of Odontoglossums, were staged with them. The rare species Angraecum Scottianum and Oncidium candidum were also noted.

Dr. MIGUEL LACROZE, Brundr, Roehampton, sent Odontoglossum Cordoba (Doris × eximium), a charming pure white flower with an occasional violet spot on the sepals, the lip bearing a ray of the same colour; also Cattleya Hesta Brundr, of good shape, the clear white flowers having a marbling of purple on the front lobe.

Messrs. J. AND A. MCBEAN, Cooksbridge, staged a small group in which were Miltonia vexillaria Queen Alexandra, one of the largest white forms and of broad proportions; the white Dendrobium Dearei, Cattleya Dowiana, and a fine form of Odontoglossum crispum with occasional spots on the sepals.

Fruit and Vegetable Committee.

Present: Messrs. Joseph Cheal (in the chair), Owen Thomas, Edwin Beckett, A. Bullock, W. H. Divers, E. A. Bunyard, Geo. P. Berry, H. S. Rivers, and J. C. Allgrove.

A fairly extensive collection of vegetables and fruits was exhibited by R. L. MOND, Esq. (gr. Mr. C. Ball), Combe Bank, Sevenoaks. The vegetables were of good average quality and represented a large number of kinds and varieties, and the fruits consisted of half a dozen Melons, black and white Grapes, Cherries, Apples, Black and Red Currants, seven dishes of Gooseberries, Raspberries, Nectarines and Peaches. The exhibit was not well staged, owing, no doubt, to lack of time and labour, therefore the various items did not show to the best advantage. (Silver Knightian Medal.)

Messrs. DOBBIE AND CO. staged tubers of about a score of varieties of Potatos; the specimens were excellent, and well displayed in baskets. Exhibition Red Kidney, the result of a cross between Myatt's Ashleaf and Snowdrop, a very handsome Potato, was the most attractive variety, but Edzell Blue, Climax (pink), Witch Hill, Epicure and Midlothian Early were also well represented. (Silver-gilt Banksian Medal.)

Dry Bulb Show.

The Society's exhibition of dry, home-grown bulbs has now become an annual event. It is invariably interesting and provides ample opportunity for demonstrating how well bulbs, notably of Daffodils and Tulips, can be grown in the British Isles. On this occasion eight classes were provided, but there was no entry in either of the two open to amateurs nor in the open one for a collection of various kinds of bulbs. Although this exhibition was not so extensive as earlier ones, and was restricted to Daffodils and Tulips, the quality of the bulbs was splendid throughout.

The best collection of twenty varieties of home-grown Daffodils, twenty single bulbs of each, was staged by THE DONARD NURSERY CO.: the bulbs were clean, weighty, and of remarkably large size; indeed, the specimens of King Alfred were exceptionally large, while those of Outpost, Magog, Golden Spur, Lucifer, and Gloria Mundi were correspondingly fine; 2nd, Messrs. J. R. PEARSON AND SONS; 3rd, Messrs. R. H. BATH, LTD.

THE DONARD NURSERY CO. gained the 1st Prize for fifteen varieties of home-grown Daffodils, ten large "family or cluster" bulbs of each; here again the specimens were exceptionally good in size and weight, showing that Irish soil and climate, plus Irish skill in cultivation, can produce bulbs which the very best Dutch growers would find difficult to match and very hard to beat.

In the class for twenty single bulbs of ten varieties of home-grown Daffodils, competitors had to include examples of Emperor, Empress, Golden Spur, Sir Watkin, Barrii conspicuus, and ornatus; Mr. J. MALLENDER was awarded 1st Prize for fine setts of Victoria, Sir Watkin, and Weardale Perfection.

Mr. GEO. MONRO, Junr., was placed 1st for a collection of twenty bulbs, each of twenty varieties, of home-grown Early Tulips; this collection consisted of very clean, even-sized bulbs, solid and weighty, staged on cocoa-nut fibre refuse in low wicker baskets. Notably good were the examples of Keizerskroom, Cottage Maid, Yellow Prince, Jacoba van Beiren, Vuurbaak, and Pink Beauty; 2nd, Messrs. R. H. BATH, LTD.

Mr. GEO. MONRO, Junr., was also 1st Prize-winner in the class for twenty bulbs, each of twenty varieties, of home-grown May-flowering Tulips, and here again the quality and presentation of the bulbs left nothing to be desired; Prof. Rauwenhoff, Europe, La Tulipe Noire, Mr. Farncombe Sanders, Pride of Haarlem, Mrs. Moon and Calliope were unusually good; 2nd, THE DONARD NURSERY CO., with large but not such shapely bulbs, and every specimen looked as though it had been rubbed with an oiled rag, as each presented a very shiny appearance; 3rd, Messrs. J. R. PEARSON AND SONS, with large specimens; equal 4th, Mr. J. MALLENDER and Messrs. R. H. BATH, LTD.

MIDLAND CARNATION AND PICOTEE.

JULY 26 AND 27.—This Society's twenty-eighth annual exhibition, held at the Edgbaston Botanical Gardens, was larger and better than the one held a year ago, there being upwards of 200 entries, against about 100 in 1917. The schedule of prizes has been rearranged, and a handsome twenty-guinea Silver Challenge Cup given by the President, W. Walters Butler, Esq., and a Gold Medal given by W. A. Nevill, Esq., have been added to the list of special awards. The all-round quality of the flowers was high, and the vase of Rosy Morn which gained for Mr. T. M. Tranter the gold medal offered for the best vase in the show was very fine, the stout-petalled blooms being unusually large, of excellent form and colour, and, when sold, they realised 22s. 6d. for the benefit of the Red Cross fund. Altogether about £20 was raised by the sale of flowers and plants for this deserving Fund.

FLOWERS IN VASES (OPEN).

The coveted prize in the first ten classes was the new Silver Challenge Cup offered to the exhibitor gaining the highest number of points. After a very close contest a local amateur, Mr. T. M. TRANTER, managed to beat the well-known and highly successful Midland growers, Messrs. A. R. BROWN, LTD., by one point only. Mr. TRANTER won 1st prizes in classes for (1) a Rose or Pink Self, with Rosy Morn, previously referred to; (2) White, with bold, heavy specimens of Bookham White; (3) Scarlet, Red, or Cherry Self, with General French; (4) Yellow-ground Fancy, edged and marked type, like Lord Steyne and Linkman, with Lord Steyne; (5) White-ground Fancy, with Fair Ellen; and (6) White-ground Picotee, with Clementine. Messrs. A. R. BROWN, LTD., were awarded 1st prizes for (1) Buff, Yellow, Orange, or Terracotta, with exquisitely shaped flowers of Madame Apollonia; (2) Yellow-ground Fancy, suffused type, like Hercules, with John Holyoake; and Yellow-ground Picotee, with W. L. Hodgkinson, shown in good style. Mr. JAMES SMITH, Darvel, showed the best Maroon, Purple, or Heliotrope Self.

THE INVISIBLE CARD CLASS.

Lieut.-Colonel PERCY SMITH provided prizes for a new class called "the invisible card class." The flowers were shown in vases supported by invisible paper cards or collars. Formal dressing was considered bad staging, and splitting of the calyx a disqualification. Messrs. A. R. BROWN, LTD., Mr. T. M. TRANTER, and Mr. JAMES SMITH were placed in the order named, and included in Messrs. BROWN'S exhibit were

splendid flowers of Mrs. W. G. Gottwaltz, Brilliancy, Mrs. George Marshall, and Pasquin.

FIRST DIVISION.

Of the seven classes in this division Mr. R. G. RUDD, King's Heath, carried off five 1st prizes. In the first class, which was for nine vases, dissimilar, he had uncommonly good specimens of Exquisite, Centurion, Bob Acres, Lord Kitchener, Pasquin, and Sweetheart. His other successes included 1st prizes in the classes for Self Carnations, in which he showed lovely flowers of Bookham White, Tubal, and Mrs. Percy Smith; Yellow-ground Fancies, with Centurion, Linkman, and Sam Weller; White-ground Fancies, with The Bride, Lord Kitchener, and Kent Faulkner; also a single vase of Fancy Carnations other than white or yellow-ground. His blooms of Joseph Reeves were much admired. Messrs. A. R. BROWN, LTD., had the best three vases of Yellow-ground Picotees, and showed W. L. Hodgkinson, Dago, and Mrs. W. G. Gottwaltz. In the class for White-ground Picotees Messrs. A. R. BROWN, LTD., were placed 2nd to Mr. C. H. HERBERT, whose flowers of Silas Baldiston, Ganymede, and Fair Maiden were very choice.

FLOWERS ON STANDS.

Twelve Self Carnations.—1st, Mr. R. G. RUDD, with first rate blooms of Purity, Wyatt Peach Blossom (Premier), Bob Acres, Border Yellow, and Farthest North; 2nd, Mr. C. H. HERBERT, who had Fujiyama, Lilian, Farthest North, and W. H. Purton in fresh condition; 3rd, Messrs. A. R. BROWN, LTD.

Twelve Fancy Carnations.—Mr. RUDD was again to the fore with shapely flowers of Lord Steyne, Osprey, John Ridd, Bombardier, and Linkman. Mr. C. H. HERBERT'S 2nd prize stand contained the Premier bloom—Liberté.

Twelve Yellow-ground Picotees.—1st, Mr. C. H. HERBERT, whose best flowers were Exquisite, Romance (Premier), Gertrude, and F. W. Goodfellow. The same exhibitor excelled in a class for twelve Bizarre or Flake Carnations, showing Spendthrift (Premier), Gordon Lewis (Premier), Master Fred, Cleopatra, and Sportsman. Messrs. A. R. BROWN, LTD., who were placed 2nd in the last named class, took the lead in a class for twelve White-ground Picotees, in which Paula (Premier), Helen, Barnard, Nellian, and Fortrose were of outstanding merit.

AMATEURS' FLOWERS IN VASES.

Mr. JAMES SMITH, Darvel, was awarded 1st prizes in classes for (1) six vases dissimilar; two each of Selfs, Fancies, and Yellow ground Picotees; (2) vase of Selfs; (3) vase of Yellow ground Fancies; (4) vase of White-ground Fancies; (5) vase of Yellow ground Picotees; (6) two vases of Fancies; and (7) two vases of Yellow-ground Picotees. Mr. S. HYSLOP, Langholm, showed the best vase of White-ground Picotees; and Mr. E. KENWRIGHT staged the winning pair of Selfs.

AMATEURS' FLOWERS ON STANDS.

In a class for six Self Carnations, Professor BURNSTALL, King's Norton, won 1st prize. His best blooms were Sunbeam, Fiery Cross, and Bookham White; 2nd, Mr. S. HYSLOP, who showed very good blooms of General French, Solfaterre, and Gordon Douglas.

Six Fancy Carnations.—1st, Mr. JAMES SMITH, who had Lieutenant Shackleton, J. J. Keen, and Pasquin in beautifully fresh condition; 2nd, Mr. E. KENWRIGHT. The last named exhibitor excelled in a class for six Yellow ground Picotees, his blooms of F. W. Goodfellow, J. J. Keen, and Constance being very clean and pure.

Mr. J. J. KEEN, Southampton, won 1st prizes in classes for (1) six White ground Picotees, and (2) six Bizarre or Flake Carnations.

The most successful exhibitors in the division reserved for amateurs who do not grow more than 300 plants were Mr. J. T. SIMISTER, Denstone; Mr. LAYLAND, Bordesley Green; Mr. A. J. HILL, Handsworth; and Mr. J. H. CAMM, Smethwick.

PREMIER FLOWERS (DRESSED).

Bizarre Carnation.—Spendthrift, exhibited by Mr. C. H. HERBERT.

Flake Carnation.—Gordon Lewis, exhibited by Mr. C. H. HERBERT.

Heavy-edged White-ground Picotee.—Ganymede, exhibited by Mr. C. H. HERBERT.

Light or Wire-edged White-ground Picotee.—Paula, exhibited by Messrs. A. R. BROWN, LTD.

Heavy-edged Yellow-ground Picotee.—Romance, exhibited by Mr. C. H. HERBERT.

Light-edged Yellow-ground Picotee.—W. L. Hodgkinson, exhibited by Messrs. A. R. BROWN, LTD.

Fancy Carnation.—Liberté, exhibited by Messrs. A. R. BROWN, LTD.

Self Carnation.—Peach Blossom, exhibited by Mr. R. G. RUDD.

PREMIER FLOWERS IN VASES.

Self Carnation.—Rosy Morn, exhibited by Mr. T. M. TRANTER.

Fancy Carnation.—Brilliancy, exhibited by Messrs. A. R. BROWN, LTD.

Yellow-ground Picotee.—W. L. Hodgkinson, exhibited by Messrs. A. R. BROWN, LTD.

White-ground Picotee.—Silas Oshaldiston, exhibited by Mr. C. H. HERBERT.

White-ground Fancy Carnation.—Lord Kitchener, exhibited by Mr. R. G. RUDD.

FIRST-CLASS CERTIFICATES.

To Crimson Bizarre Spendthrift, exhibited by Mr. C. H. HERBERT; to White-ground Picotee Charity, exhibited by Mr. J. J. KEEN; to Yellow-ground Picotee Mrs. G. W. Gottwaltz, exhibited by Messrs. A. R. BROWN, LTD.; to Yellow-ground Picotee W. L. Hodgkinson, exhibited by Messrs. A. R. BROWN, LTD.

SPECIAL PRIZES.

The Gold Medal offered to the exhibitor gaining the greatest number of points in the first division was awarded to Mr. C. H. HERBERT, and the Gold Medal in the second division was won by Mr. JAMES SMITH. The Writers Butler Silver Medal, offered to the most successful exhibitor in the third division, was won by Mr. J. T. SIMISTER.

HONORARY EXHIBITS.

Silver Medal to Mrs. THOMPSON, for Cacti; to Mr. J. SCANDY, for Sweet Peas; and to Mr. H. J. JANNER, for Violas.

TRADE NOTES.

CHAMBER OF HORTICULTURE.

THE question has been raised as to why Trade Federations and Associations were not officially invited to the preliminary consultative meeting of the Chamber of Horticulture, held on the 17th ult. at Donnington House, Norfolk Street, Strand. The explanation is given by the Hon. Secretary, Mr. H. Morgan Veitch, in the following letter:—

"The recent meeting was merely convened for the purpose of discussing in a preliminary way whether the scheme, if launched, would be assured of the necessary support and success. For this purpose those of us who for some years past have been hoping to see a Chamber of Horticulture formed, invited a few friends to attend and give us the benefit of their views, but no Federations and Associations were invited officially, as it was felt that this would be premature until we had something definite to put before them.

"Now that the scheme is assured of success steps are being taken to draft the form of constitution for approval, and this will be submitted at a full meeting to which those interested in any branch of horticulture (including Trade Federations and Associations) will be publicly invited. It is proposed to hold this meeting in the autumn, as the month of August is too busy a season for many to attend. The date and place of the meeting will be announced in due course.

"I venture to think that the trade already recognises that there are many questions affecting horticulture as a whole which can usefully be dealt with through a united body representing all branches, and that there are many instances in which an injury to one branch of horticulture must inevitably act indirectly to the detriment of other branches.

"The functions of the Chamber of Horticulture would, in fact, be very similar to those already performed by the Railway Clearing House on behalf of the various railway companies; these, of course, manage their own internal affairs, but when any danger threatens railway interests as a whole, or when any constructive reform is desirable, which would prove of universal benefit, then the various companies sit and act as one body through the medium of the Railway Clearing House. *H. Morgan Veitch, Hon. Secretary.*"

MR. DAVID KING.

THE visitors to the Royal Horticultural Society's exhibition on July 30 included Mr. David King, of Osborne Nurseries, Murrayfield, Edinburgh, who came especially to see the home-grown bulbs, and, incidentally, to make enquiries concerning plants suitable for forcing to produce cut flowers early in the coming season. Mr. King received a hearty welcome from many brother Scots and many southerners who have made his acquaintance at horticultural gatherings in Edinburgh.

RESEARCH IN PLANT BREEDING IN SCOTLAND.

A CONFERENCE on the subject of the establishment of a research station in plant breeding in Scotland was held in Edinburgh on the 26th ult., presided over by the Secretary for Scotland, Mr. Munro, M.P., who was accompanied by Sir Robert Wright and Dr. Greig of the Board of Agriculture for Scotland. Representatives of the Highland and Agricultural Society, the Scottish Chamber of Agriculture, the Scottish Seed Trade Association, and the National Farmers' Union of Scotland were present. The conference was addressed by the Secretary for Scotland, who emphasised the importance of the proposal, and stated that the Government would grant pound for pound of every sum subscribed for the promotion of the object for which they were met. On the motion of Dr. Douglas, of Auchlochan, seconded by Mr. H. W. B. Crawford, chairman of directors of the Scottish Chamber of Agriculture, a resolution commending the project was unanimously approved. Mr. W. Cuthbertson, of Messrs. Dobbie and Co., supported the proposal. A further motion in favour of the appointment of a committee to confer with the Board of Agriculture was moved by Mr. Gardner, Hillingdon, the committee to consist of representatives from a number of associations, including the Scottish Seed Trade Association, and agreed to.

It was seconded by Mr. D. Bell, the president of the Scottish Seed Trade Association, who said that he was so convinced of the national benefit to be derived from the scheme that he would give £1,000 towards its establishment. At a previous meeting the Highland and Agricultural Society voted a sum of £2,000 towards the fund. The promoters hope to obtain a minimum sum of £20,000.

MR. E. J. BAYLEY.

FORMERLY with Messrs. Dickson and Robinson, and Messrs. J. Veitch and Sons, Mr. E. J. Bayley has now commenced business on his own account as a seed, plant, and bulb merchant at Shrewsbury, with shop and offices at 4 and 5, Corn Exchange Buildings, and grounds at Bayston Hill.

CROPS AND STOCK ON THE HOME FARM.

THE PLOUGHING OF GRASS LAND.

MUCH correspondence is going on in the daily Press as to the wisdom of ploughing more grass land. No doubt in some parts, where skilled labour is scarce, it is not wise to add to the existing arable land for fear of neglect of the proper cultivation of that already in hand. I have no doubt whatever that where moderate pasture-land exists and it is not needed for stock much better results can be had from the land under the plough, especially when we see the excellent crops of Oats, Wheat and Potatos growing this year on recently ploughed-up pasture.

Where, however, grass land is simply ploughed up and sown without any special cultural preparation or manurial aid good results cannot be expected, especially if the field under cross cropviously produced but moderate crops. Too many persons treat the land in quite an inconsiderate manner, and then complain of the principle of ploughing-up if success does not follow their puny efforts. There is an old adage in

connection with the land. If you put nothing in, what can you expect to get out of it?"

SHEEP FOR STOCK.

Those who keep sheep with the double object of producing mutton and aiding corn production will be commencing their flocks for the coming season by drafting out ewes useless for breeding, and adding to the flock their young ewes—last year's lambs—or by the addition of new stock from other flocks.

The best kind of sheep to keep is entirely a matter of circumstance. No breed equals the Hampshire Downs where close folding for cereal crops to follow is the main aim in keeping sheep. No other breed produces lambs of such size and quality in so short a time. The South down breed may give mutton of higher quality, but is not so suitable for close folding, especially where the land is heavy. In the latter case a suitable cross is provided by Hampshire Down ewes mated with Southdown, Oxford, Suffolk, or Leicester rams. Where there is a large area of grass land and only a small area of arable land, the Cheviot breed is useful, as it succeeds better on grass than the Hampshire Down breed; these sheep can also be placed on arable land for eating off roots preparatory to a cereal crop.

If Hampshire Downs or any other pure breed is favoured I strongly advise the registration of pure-bred animals, as these always command a higher price than cross-breds of any kind. Where lambs are required in January, and that is considered a good time for the Hampshire Down breed, mating should begin in early August. One ram to fifty ewes is sufficient.

LATE TURNIPS.

No time should be lost in sowing the latest Turnips for sheep food in March and April. Hardy Green Round is one of the best varieties. The roots bury themselves well under the surface soil, and are not nearly so liable to damage by frost as those which stand out of the ground. Rape added in small quantity provides useful and appreciated food. One and a half pound of Turnip and half a pound of Rape per acre will be ample. I prefer to drill the seed, especially where Charlock grows freely, as the opportunity is then provided for running the horse hoe through the ground quite early, and thus getting rid of much Charlock, but where broadcast sowing is practised no such opportunity is afforded, and the Charlock quite smothers the Turnips and seriously affects their progress. It is wise to add 3 cwt. of superphosphate per acre at the time of drilling.

HARVESTING WHEAT.

Given a week's sunshine the cutting of this cereal should be general in the South. To obtain Wheat of extra "strength," bright red in colour and full of gluten, cutting should take place when the corn is three-quarters ripe; indeed, the straw may still have a green hue. When Wheat is allowed to become thoroughly ripe before being cut the corn is very liable to "brit," i.e., shake out by handling. In this way much corn is lost during carting.

SURFACE CULTIVATION.

When the weather is dry, hoeing among roots, especially Mangolds, is of great benefit to the crop, admitting air to the roots as well as removing weeds, which rob the soil of plant food and smother the growth of the crop. The early-sown Mangolds will now be too large in the leaf to permit the use of the horse hoe among them. Late sown plots can be so hoed, and where the plants are not growing luxuriantly 1 cwt. of sulphate of ammonia per acre will accelerate growth.

UTILITY POULTRY.

Rhode Island Red is one of the best breeds, the hens laying large brown eggs freely during the autumn and winter, and there is no denying the fact that brown eggs have a fascination that white eggs do not possess. The chickens grow sturdily, and make fairly good table birds. The feathers are dark red and legs yellow. The Plymouth Rock also lays brown eggs, and especially good are the "barred" type, which are good foragers and fine table fowls, a little coarse perhaps, but useful where weight is desirable. White and Buff Orpingtons also lay brown eggs. The latter are especially good in winter, while the former give eggs in July, when many other breeds are resting. Both these breeds give good table fowls, are hardy, and easily reared. Hens of the Buff type make good mothers, and that is a trait most useful to the poultry keeper.

Layers of tinted eggs are White and Silver Wyandottes, both of which lay rather small eggs. The most prolific layers are the White Leghorns; the male birds should be pure white in feather, with a bold, arching tail, a huge, richly-coloured comb, pure white ear lobes, deep orange-coloured legs, and a bold, upstanding carriage. Hens of a good strain of Black Minorca lay the largest eggs. Both of the last-named breeds are of little value for table purposes. A strong point in their favour as egg producers is that they are non-sitters. *E. Molyneux.*

BLANKET WEED IN PONDS: *R. H.* When the Blanket Weed is a great nuisance in a pond or lake it may be destroyed either by spraying with a copper sulphate solution, or by dragging copper sulphate through the water in parallel lines, as advised on p. 40, in answer to *J. E.* In some cases spraying may be a more convenient method than dragging, especially when the pond or lake is narrow and the weed is abundant at the surface of the water. The spraying mixture should be made by dissolving copper sulphate at the rate of 1½ oz. in 2 gallons of water; so far as we are aware spraying with this solution will do no harm to the fish.

CROPS DAMAGED BY HAIL: *E. H. M.* As the fruit trees have been defoliated so severely it will not be desirable to impose a further check by summer pruning; in all probability new growth will start at the ends of the shoots, and the new leaves will assist the trees, but if the leafless shoots were summer pruned the basal buds would endeavour to push into growth. The Dwarf Beans are not likely to recover, but if the damaged portions of the Runner Beans are cut away and the remainder tied up to the supports, sufficient branches should form and give a late crop of Beans. Do not prune the Roses, as every leaf is valuable. Cauliflowers are useless if the hail has cut out the centres; obtain strong young plants and make a new plantation at once. The late Potatos, having been so badly injured, can hardly be a success, but they should not be lifted so long as there is a green leaf and shoot above ground.

GRAPES WITH SPLIT BERRIES: *G.* The Black Grapes (Lady Downe's Seedling) and the small bunch of white ones, probably Foster's Seedling, with split or cracked berries, suggest that the roots of the Vines are subject to an excess of moisture. The position of the vinery and outside borders is such as to aggravate the trouble, but much may be done to prevent cracking in the future by covering the outside border with corrugated iron or old frame lights during very wet weather, and during very cold or snowy periods in winter. Allow an extension of lateral growth, especially towards the top of the rods in the case of Lady Downe's Seedling and any other varieties that have hitherto shown a tendency to produce cracked berries. Vine mildew is not present, but a mould has formed where the split berries are in contact with each other, and decay has commenced. The long bunch of Grapes represents the popular Muscat of Alexandria variety; this needs more warmth than the other varieties to enable it to perfect its fruits. A few of the berries show evidence of a light attack of "spot" (Gloeosporium ampelophagum). See reply to *H. G.*, p. 20.

HUMOGEN: *J. A.* Humogen is a proprietary preparation, said to contain the nitrifying bacteria so essential in the soil. Experiments have been carried out with it on various crops, and whereas in some cases the results have been good, in other instances they have been negative. With regard to the failure of the Apple crop, this is due to the unseasonable weather prevailing at the time the trees were in bloom.

LECTURES TO ALLOTMENT HOLDERS: *G. P.* Our advice is that you arrange your own syllabus, and depend upon your practical knowledge and experience when lecturing. Commencing with soil management and manures, proceed with various garden crops, dealing with these in groups, such as roots, pod-bearers, greenstuffs and salads, Onions, Leeks and Shallots, Tomatos, Marrows and Cucumbers; seed sowing, transplanting, insect pests, and diseases, will provide ample scope for separate lectures. Arrange the syllabus so that the subjects are dealt with so far as possible at suitable times, and having settled the main subjects and dates, set out under each heading the most important points. For instance, Potatos will be a subject for one evening, and under this heading you might put Selection of Setts, Change of Seed, Varieties, Sprouting, Planting, Manures, Earthing up, Spraying, Lifting, Storing. Follow on this suggestion with the subject put down for each evening, and you will have a complete syllabus for your series of lectures. The set of printed lectures on "Vegetable Cultivation," published by the Royal Horticultural Society, may be helpful and suggestive.

NAMES OF PLANTS: *A. S.* Artemisia tanacetifolia. — *B. S.* Euphorbia Lathyris (Caper Spurge).—*H. S. B.* 1, Lathyrus grandiflorus; 2, Lychnis chalcedonica; 3, Sedum spectabile.—*E. W.* 1, Platycodon grandiflorum; 2, Browallia demissa; 3, Solanum decurrens.—*F. D. L.* (a) Rosa sp., probably sinica; (b) Crinum Powellii; (c) Spiraea Bumalda var. Anthony Waterer.—*W. J. H.* Lysimachia vulgaris.—*S. W. J.* 1, Ficus Parcellii; 2, Phyllanthus glaucescens; 3, Helxine Soleirolii.—*J. M.* We do not recognise the variety of Rose; send to a nursery grower who can compare the variety with those in his collection.

ONION FLY: *H. S.* Pamphlets dealing with the life history of the Onion Fly and the means for preventing attacks of this pest, may be obtained on application to the Board of Agriculture, Whitehall Place, Westminster.

POINTS FOR VEGETABLES AND FRUITS: *A.* The Royal Horticultural Society's *Code of Rules for Judging* will be helpful to you in estimating the point values of vegetables and fruits staged at an exhibition. According to this *Code* the maximum points allowed for the kinds you mention are as follows:—Round and Kidney Potatos, 8; Broad and Longpod Beans, 6; Runner and Dwarf Beans, 7; Cabbage, 6; Celery, 8; Marrows, 6; Cucumbers, 7; Peas, 8; Lettuce, 6; Parsnips, 6; Beet, 6; Carrots, 8; Onions, 8; Currants, 3; Raspberries, 5; Gooseberries, 4; Strawberries, 6. Loganberries are not listed in the edition quoted from, but these should be pointed in the same way as Raspberries.

POTASH FROM FLOWER STEMS: *M. L.* The store of potash may be increased by burning the old stems of perennial Sunflowers and Jerusalem Artichokes, as well as those of Giant Sunflowers. The ash should be gathered when dry, and stored in a dry shed.

WEED IN POND: *J. E.* The plant you send is Potamogeton pectinatus. As a strong specific would probably be necessary to kill this weed it would not be safe to use copper sulphate in the presence of trout, and we can only suggest that you should cut the growth as close to the bottom of the pond as possible and drag it out before it seeds.

NOTES FROM KEW.—VIII.*

BEING in my fortieth year at Kew I have seen a considerable number of giant blooms and go. The great Amorphophallus Titanum arrived at Kew as a tiny seedling in the same month and year as I did. Sir Joseph Hooker was careful to impress us with particulars of its wonderful proportions, and after ten years exactly, June, 1889, we had it in flower. It stood over the great Water Lily tank, and those who saw it in its prime experienced delight tempered with disgust, for its fœtid odour was in proportion to its great size. The tuber, before it flowered, weighed 57lbs., but the enormous inflorescence reduced it considerably. A peduncle as thick as a blacksmith's arm, a great club-like spadix 5 feet long, and a spathe a yard deep and 4 feet across were all developed in sixteen days, so that we could almost see them grow. A swarm of bluebottle flies buzzed round the flower, which lasted only forty-eight hours, when the odour ceased. A second plant flowered about ten years later, but there is no plant at Kew now.

Another giant with a powerful and disagreeable odour, which flowered first in Messrs. Henderson's nursery at Maida Vale under Mr. James O'Brien's care, also flowered some time later at Kew. When figuring it in the *Botanical Magazine* in 1881 (t. 6,567), Sir Joseph Hooker stated that in many respects it was one of the most gigantic of Orchids. "I know of none with so stout a rhizome, so large a leaf, or such massive inflorescence." It was named by Reichenbach in compliment to Dr. Beccari, to whom Kew was indebted for the first living plant of the titanic Amorphophallus. I doubt if there is a plant of Bulbophyllum Beccarii anywhere in cultivation now. Other giant Orchids which flowered at Kew in my time included the plant of Grammatophyllum speciosum which Mr. Sander obtained at great expense from Malacca for the Chicago Exhibition, but gave to Kew instead, where it flowered in 1902. It is alive still, but much reduced in size, owing to an overdose of manure, which nearly killed it. The late Mr. James H. Veitch saw a specimen of this Orchid in the Botanic Gardens, Penang, which measured 42 feet in circumference, and bore 30 spikes, each 7 feet high, on which there were thousands of big yellow and brown flowers. Lissochilus Mahonii from Uganda, named after John Mahon, one of Kew's best men, who died of sleeping sickness contracted in Uganda, flowered at Kew in 1905, its spike, 8 feet high, bearing about three dozen flowers, in shape not unlike those of Disa grandiflora and twice as large, with pink, wing-like petals and a large, green, yellow and purple lip. It died soon after flowering. Eulophiella Peetersiana had ceased to be exciting when it flowered at Kew in March, 1908.

Giant Palms, Cycads, and Pandanads have made their *début* at Kew. There was great rejoicing over the double Cocoa nut, two noble plants having been raised, and, when old enough, planted in the Palm House, where cold winters proved fatal to them. There never was a worse home for tropical plants than the Kew Palm House. It is an engineer's structure, very fine and imposing, but about as well fitted for the cultivation of tender plants as King's Cross Station. Only the strong and long suffering among the plants from the tropics can stand its winter conditions. The severe winter of 1916-17 was fatal to our large double Cocoa-nut and many other ultra tropical plants, including the common Cocoa nut, some Pandanads and a good example of Para Rubber (Hevea brasiliensis). The structure is all right; it is the internal arrangements of the Palm House that are all wrong.

The next largest tropical house is No. 4 and in it many big things have grown to perfection. Anderstia nobilis is quite happy there, and another big legume, Baikiæa insignis, is in prime condition, and flowering freely at the present time. This West African tree is even more wonderful than the Anderstia. Mr. Willis has tried to show what its flowers are like in the photograph reproduced in fig. 18, but the picture falls a long way short of the real thing; yet, no shorter than the description in the *Flora of Tropical Africa*. The flowers are so delicate in texture and so fugacious that only a clever, patient artist with some imagination could represent them in a picture, and it would have to be in colour. The leaf has two pairs of leathery leaflets which may be 10in. by 4in., and the flowers are in pairs or threes on the end of the short branches. In bud they are finger-shaped, with a dark-brown, velvet-like covering. They open quickly and the five petals spread out Cattleya-like, four of them 6in. by 3in., pure white, and as delicate in texture as Poppy petals. The fifth is narrower, infolded, clear sulphur yellow, and may be called a yellow lip. The only flower at all like this is that of the climbing Camoensia maxima, also from West Africa, where it is said to adorn the loftiest trees with its splendid bunches of milk-white, golden-edged flowers. This flowered at Kew in 1896, and although it appears to be happy enough, it has not flowered since.

These are not plants for Covent Garden, nor yet for the villa greenhouse. They are among the wonders of the tropics, and are grown and shown at Kew and other botanical gardens for the same reason as the elephant, giraffe, polar bear, python, chimpanzee, and such like wonders of the animal kingdom, are shown at the Zoo.

Another giant, also in flower now in No. 4 house, is Amomum hemisphæricum (figs. 19 and 20), a native of Java. It has been at Kew since 1895, and for the last fifteen years or so has spread itself over a bed in No. 4, by means of its thick, Ginger-like rhizomes. The noble, leafy, frond-like stems are from 10 to 14 feet high, and the largest leaves over 2 feet long by 7 inches wide, dark green above, brown-red beneath. The flower-scape and head are drum-stick like, the scape being 4 or 5 feet long, and the head 5 inches across. The figure in the *Bot. Mag.*, t. 7,592, represents a young flower-head, partly developed, other heads having the outer bracts reflexed, showing a rich scarlet colour and suggesting the Waratah (Telopea). I have never seen A. imperialis alive; the figure of it in *Bot. Mag.*, t. 5,192 (1832), where it is called Alpinia magnifica, was made from a plant flowered in the garden of Lord Milton, Wentworth, who obtained it from Mauritius. Allowing something for artistic licence, that figure is not unlike the Kew plant under notice, the only marked difference between them being in the length and width of the bracts. I wonder if some one has blundered, and whether the two are really the same species. A. Granum paradisi, the seeds of which are known in commerce as Melegnetta Pepper or Grains of Paradise, is a very different plant, as also are all other species of Amomum that I have seen. Be the name what it may, the plant now grown at Kew as Amomum hemisphæricum is a magnificent member of the great Ginger family.

Lilium sulphureum is, in a way, certainly as grown at Kew, the giant of the genus. It has always grown well in a greenhouse, formerly in the Himalayan House, and in recent years in the conservatory (No. 1) where it is in flower now. From one bulb, probably the size of a man's head, there spring three stems, each over 10 feet high and as thick as my thumb, bearing altogether twenty magnificent blooms, each 8 inches long and about 6 inches across, pale sulphur yellow, tinged outside with purple, and delightfully fragrant. This is the only one of the Burmese Lilies that behaves well under cultivation. L. primulinum, L. Bakerianum and L. Lowii were always "miffy," and they left us years ago. None of them will thrive out-of-doors. *W. W.*

ORCHID NOTES AND GLEANINGS.

CATTLEYA WARSCEWICZII ROCHELLENSIS.

INTRODUCED and first flowered by Messrs. Siebrecht and Wadley of New York, and described in the *Gardeners' Chronicle* of November 10, 1917, it is highly satisfactory to see by a flower sent by Samuel Gratrix, Esq., West Point, Whalley Range, Manchester (gr. Mr. J Howes), that a vigorous specimen of this valuable albino is still in cultivation. The specimen sent is 8 inches across and of fine shape, pure white, with a suspicion of blush tint in the front part of the lip, around the clear yellow disc. There are several varieties of white forms of Cattleya Warscewiczii, culminating in the pure white C. Warscewiczii alba var. Firmin Lambeau, with which M. Firmin Lambeau, of Brussels, secured a First-class Certificate and Gold Medal at the Royal Horticultural Society, July 16, 1912, and for which Messrs. Armstrong and Brown of Tunbridge Wells, paid 210 guineas at the dispersal of the late Mr. J. Gurney Fowler's collection in 1916.

LAELIO-CATTLEYA IVERNIA VAR. MURIEL WILSON.

A LARGE and gorgeously coloured flower of this remarkable variety of the cross between Laelia tenebrosa and Laelio-Cattleya callistoglossa (L. purpurata × C. Warscewiczii) is sent by Samuel Gratrix, Esq., West Point, Whalley Range, Manchester. In many of the varieties of L. C. Ivernia the narrowing influence of L. tenebrosa is against floral perfection, but in this variety the best features of L. C. callistoglossa are retained and amplified by Cattleya Warscewiczii, which has given the intensely dark ruby-red lip, shading to maroon in the centre and to dark violet towards the margin, as well as the yellow patches on each side of the tube. The petals are 5 inches in width and gracefully arranged, both sepals and petals being bright rosy mauve, with strong white bases to the midribs.

CATASETUM DARWINIANUM WITH MALE AND FEMALE FLOWERS.

THE illustration (see fig. 21), prepared from a photograph taken by Mr. C. P. Ratfill, of a plant which flowered at Kew some time ago, well represents the character of both sexes of this very interesting species and the wonderful arrangement of the flowers to secure fertilisation by insect aid. The setae, upon which the slightest touch by the exploring insect frees and ejects the pollinia to be borne by it on its visit to the female flowers, are invitingly displayed on each side of the cavity in the labellum, leading to the nectary which attracts the insect, as seen in the central flower of the upper three male blooms. The two female flowers are totally different in shape, their labellums being fleshy, helmet-shaped, usually reversed, and green tinged with brown. The uniformity in the colouring and arrangement of the female flowers in species bearing totally different male flowers is very remarkable, so far as they have been tested by the proportion of species which have produced flowers of both sexes in cultivation. The flowers are sometimes borne on separate spikes, but occasionally both are on the same inflorescence, as in the example now illustrated.

(Photograph by E. J. Wallis.

FIG. 53.—BATEMAN INSIGNIS: FLOWERS WHITE AND YELLOW.
(SEE p. 55.)

Species of Catasetum are most interesting, and it is to be hoped that they and others equally interesting Orchids, will not be allowed to drop out of cultivation. Grown in pans or baskets for suspending in an intermediate house and subjected to a drying off process in the resting season, similar to that given to deciduous Dendrobiums, and a rather lower temperature during that period, they are not difficult to cultivate successfully.

STRAWBERRIES.

PREPARING RUNNERS FOR PLANTING.

Now that all the fruits have been gathered, runners are very numerous in Strawberry plantations. If no new plants are needed all runners should be cut back close to the old crowns, but where young stock is desired a sufficiency of runners must be secured at once, either to pot up for forcing or for new plantations. Great attention is usually given to Strawberries intended for forcing, but for new plantations they are often lifted and planted without any preparation. This is a great mistake, as with proper care a new plantation will always yield a quantity of fruit the year after planting, but plants carelessly treated seldom bear a crop until the second year.

The best plan is to layer each runner into a 3 inch pot; place a few leaves or a little rough material at the bottom of each pot, then fill to the rim with loam to which a little manure has been added, and make the soil very firm. Pot rooted runners, but if the roots are only beginning to show, secure the runner with a peg close to the neck of the plant'let.

In dry, bright weather water must be supplied daily; when the runners have been layered ten days or so, and the roots have taken a substantial hold of the new soil, sever them from the old plants, and stand the pots on a hard base. The foliage will droop a little for a day or two, but in a week or ten days the plants will be ready for potting or planting, which should be done before the pots are filled with roots.

Another plan is to cut fibrous turf into pieces about 4 inches square; turn them grass side downwards, and peg the runners down to them. The roots soon penetrate the turf and confine themselves to it. Plants so treated invariably grow well, and this plan is far superior to that of allowing the runners to root into the ordinary soil of the beds. Many of the roots in the latter case will be broken in the lifting, some will have no soil attached to them, and all will receive a check. After planting it is necessary to pay due attention to watering to encourage growth, because Strawberries which have not made much good progress before cold weather sets in cannot give a full crop the following season. *James A. Paice, Aldenham Vicarage Gardens, Watford.*

PLANTING RUNNERS IN SMALL GARDENS.

THE scarcity of fruit this season will suggest the planting of Strawberries in small gardens, as Strawberries give quicker returns than any other kind of fruit: they may, indeed, be grown successfully as an annual crop, and in that sense will escape the restrictions placed on perennial crops in allotments. Now is the time to plant in order to secure a crop next year; a plentiful supply of farmyard or stable manure should be dug into the ground, allowing time for the soil to settle down afterwards, as it is especially necessary to make the ground very firm around the young plants when they are planted. Pinch off new runners as soon as they appear, and encourage growth as much as possible. Suitable distances for the first year are one foot between the rows and 9 inches between the plants: after the first crop has been gathered alternate rows and alternate plants

should be removed, thus leaving the rows 2 feet apart and the plants 18 inches apart in the rows.

For regular cropping and good flavour no strawberry surpasses Vicomtesse Hericart de Thury (syn. Garibaldi) where the soil is favourable; if the soil is light Royal Sovereign is a better variety, and generally proves to be a heavy cropper, but in bad seasons it often suffers from late frosts when the Vicomtesse escapes injury by reason of its abundant foliage and compact habit. *W. H. Divers, Westdean, Hook, near Surbiton.*

LARGE FRUITS.

I am induced to write a few words respecting what may be called abnormally big fruits of Strawberries. Early in the present season a dish of an unnamed variety of fruits was exhibited by Mr. Prince, from the Hatfield Gardens. These fruits were remarkably well grown, and had travelled well, but instead of providing "three dates" these would have provided three. The Hatfield Gardens have a reputation for big Strawberries: some of the finest fruits I ever saw were shown by the late Mr. Norman many years ago; these were forced specimens of Sir Charles Napier and President. In my earlier years I remember Sir Harry, a big, ugly fruit at its best, and I am led to ask, do we need such big Strawberries? Personally I think not, for a medium sized fruit is almost always chosen by the connoisseur. *James Hudson.*

CULTURAL NOTES

TREATMENT OF VEGETABLES IN DRY WEATHER.

The value of mulching plants in hot, dry weather has been emphasised this season. Our Peas were mulched with long, strawy litter as soon as they were staked; the litter was placed as high up the stakes as possible to keep the hot sun from the haulm, and when water was given to the roots it was allowed to soak through the litter. Thrips soon became troublesome, but spraying with a solution of nicotine by means of a Knapsack sprayer on two or three occasions weekly kept them in check. If the crops are stunted in growth they should be given a light dusting of sulphate of ammonia and watered immediately afterwards. The method of growing Peas in trenches, especially on light soils, has much to recommend it, and if the trenches are made wide enough, and the Peas sown in double rows, they will succeed better than when sown broadcast along the trenches, and are more easily thinned. This method permits of the application of a mulch of short manure, and allows air to reach the plants freely; for late Peas, where mildew is prevalent, this method of planting is a great advantage, and results in a saving of seed.

In dry weather Broad Beans are greatly benefited by a mulch after the soil has been drawn up to the trench, and the same is true of Runner Beans. The practice of raising Onions in boxes indoors, and transplanting them in the open, has again proved successful, seeing that the Onion maggot has been very prevalent on plants raised from seed sown out-of-doors in the spring. Mulching the plants with horse manure, dusting them with soot, and watering them in the evenings, have kept them growing freely, but watering without mulching is detrimental to them. The present showery weather, with sudden bursts of sunshine, will soon cause mildew to appear on the plants; as a preventive damp them, and afterwards dust the growth with equal parts of lime and sulphur. Celery has been much troubled with the leaf-mining maggot (Tenbritis oneopordinis); frequently dusting the foliage with soot when the leaves are damp, and repeating the treatment when the soot is washed off, will prevent the pest spreading, or the plants may be sprayed with a solution of nicotine, preferably made from Auto shreds. If Celery is stunted in growth through the dry weather, give a light application of nitrate of soda and wash the fertiliser in, when the plants will grow readily and be less susceptible to attacks of the maggot. *J. B. Wedds, Eaglehill Gardens, Reading.*

TREES AND SHRUBS.

DABOECIA POLIFOLIA.

Hardy shrubs that flower from July onwards include several members of the Heath family. The Connemara Heath, Daboecia polifolia, is a delightful plant during the whole of its flowering period, which extends from early in June to November. It is a free-growing little shrub usually reaching a height of 12 inches, and sometimes more. The flowers, which are borne in short terminal racemes, are egg-shaped, and

(Photograph by E. J. Wallis.

Fig. 79.—AMORPHUM HEMISPHAERICUM: SHOWING PART OF RHIZOME, BASE OF STEM, AND INFLORESCENCE, THE STEM OF WHICH IS 5 FEET LONG.

(See p. 58.)

individually larger than those of any of its generally grown allies. In colour the typical form is of a pleasing shade of rosy-purple, but there are other well-marked varieties. The variety alba shows a decided contrast to the type; atropurpurea is remarkable for its deep, rich colour, whilst bicolor (or versicolor) is a distinct and singular variety. The latter bears both white and purple blossoms on the same plant, and even on the same spike, while some flowers are partly white and partly purple. As implied by its popular name this Daboecia is found in Ireland, but it also occurs over a considerable tract of country in Western Europe. It is sometimes known as Boretta cantabrica. A fairly cool yet light, moist soil suits it best. Like most of its allies, it resents the presence of lime in the soil. *W. T.*

FOREIGN CORRESPONDENCE.

OLD GARDENING BOOKS.

In co-operation with the Library of the Department of Agriculture, which is trying to build up its horticultural collection as far as possible, I have attempted to compile a list of gardening and pomological works published prior to 1800, and have actually located many of the books themselves in some four or five libraries of this country which are rather rich in gardening literature. However, the great proportion of the 16th and 17th century works are as yet unknown and unknown to me. Under these circumstances the publication in *The Gardeners' Chronicle* of notes like those of Mr. E. A. Bunyard on Cotton's *Planter's Manual*, and Mr. C. H. Payne on "Old French Gardening Books," to mention only two of the most recent ones which have delighted me, is of great value and importance.

Mr. Bunyard's identification of Cotton's *Planter's Manual* was new to me, as my attention had never been directed to Cotton, but his further identification of *Instructions pour les arbres fruitiers*, credited in the Catalogue de la Bibliotheque de la Societe Nationale d'Horticulture (1900), also in M. Gibault's admirable paper in the Journal of that society for November, 1905, to Rene Triquet, as being actually by François Vautier, was one I had long suspected, upon finding an entry of the same title in Sagner's Bibliotheca Botanica under "Vautier, N." (sic).

Sagner's I have often wondered if the "one of the Abbey of Saint Vincent in Fraunce," from whom Miscall's book was said to have been translated, might not have been Davy Brossard, but never having seen a copy of *L'art et maniere de semer pépins et de faire pepinières*, I was unable to prove the fact which Mr. Payne has now shown in your columns. Many of Mr. Payne's identifications are, of course, fairly well known, as Evelyn's *French Gardener*, and London and Wise's *Retir'd Gardiner*, but others, like Bishop Fleetwood's appropriation of Vallemont, and the translation published at Dublin in 1758 of De Combles, *Traité de la culture des pêches*, as well as the English version of Venette, of which the identity was fairly well concealed, I had never seen attributed to the actual authors, though it was possible to identify them, partly through sheer lucky guessing, and partly through the courtesy of interlibrary loans, which enabled me to compare books from libraries separated by many hundreds of miles. *Marjorie F. Warner, Bibliographical Assistant, Bureau of Plant Industry, U.S. Department of Agriculture.*

PLANT NOTES.

SEDUM HIRSUTUM BOETICUM.

At a casual glance this Sedum resembles some of the forms of S. album, but the habit is dwarfer, compact, and the flowering stems only 5 inches high. The white flowers are of the largest size for the last-named species, and produced in terminal cymes. A closer inspection reveals other differences, for the fleshy, oblong leaves of the short, barren shoots are densely covered with glandular hairs, which would fit it to live under very dry conditions of soil or climate. The leaves on the flowering shoots are much less hairy, being only thinly pubescent. The plant is a native of South Europe, but neither the type nor variety seem recorded as having been introduced to cultivation before. It has been flowering for some time past in the Alpine house of the Royal Horticultural Society at Wisley. Judging from its appearance it would be most suitable for wall gardening in this country, as it should be kept dry at the roots during winter. *J. F.*

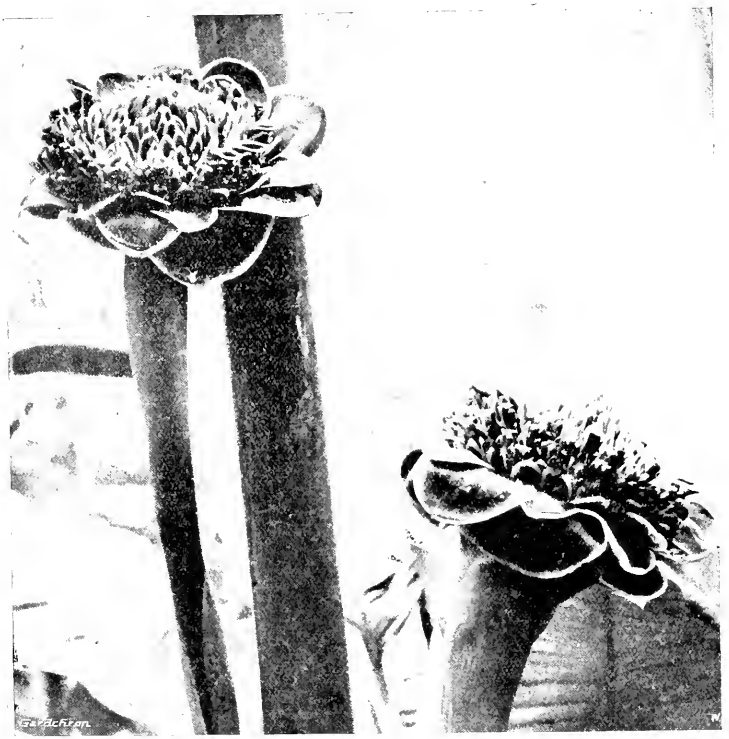
HARDY FLOWER BORDER.

PLATYCODONS.

PLATYCODONS, or Balloon Flowers, though appreciated where seen, are not common in gardens. This is not due to their lack of beauty or interest, as they are attractive plants in every respect. Their glaucous-looking leaves and loose spikes of flower are of considerable value in a garden, while the varnished, balloon-shaped buds, which open to a good size, give them an appearance sure to attract the observer. Their comparative absence from gardens is mainly due to the circumstance that they are often lost in winter, owing sometimes to their dislike to the alternations of wet and cold, and sometimes to attacks of slugs and snails. The fleshy roots are easily damaged, and it is no uncommon thing to see good plants going off in a season they are rare. The forms of these are P. g. plenum, with double purple blooms, and P. g. album plenum, with white flowers.

One of the most delightful of the Balloon Flowers is P. g. Mariesii, sometimes accorded specific rank as P. Mariesii. It is dwarfer, and has comparatively large flowers, of a deep, glossy, purple-blue. A still dwarfer variety, called minimum, is also, I believe, in cultivation, but I have not met with it. In order to avoid the risk of loss in winter, in cold districts Platycodons should be grown in dryish soil, and in some parts, as well as where slugs are destructive, it is well to cover the crowns in winter with a few dry ashes.

Platycodons are generally raised from seeds, which are produced freely, and germinate readily if sown in pots under glass in spring. *S. Arnott.*



(Photograph by E. J. Wallis.

FIG. 20.—ANOMATUM HEMISPHAERICUM: FLOWER-HEADS 5 INCHES ACROSS, BRACTS BRIGHT SCARLET. (SEE p. 55.)

The Platycodons in commerce are generally recognised simply as varieties of Platycodon grandiflorum, sometimes called Campanula grandiflora. This species is a native of China and Japan, and has generally purple, bell-shaped flowers in a wild state. The author of *The Garden of Japan* tells of seeing "On the mountains the magnificent purple Campanula, Platycodon grandiflorum, with pale lilac and double varieties in the gardens. I shall never forget the effect of thousands of these beautiful flowers carpeting the hillside of Bandai-san."

This form is in cultivation, and is a good plant, which grows from 2 to 4 feet high. It is synonymous with P. chinense. The white variety, P. g. album, is a charming plant also, and the lilac one mentioned in the above work is occasionally seen in British gardens. The double varieties are also in commerce, though

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

CELERY.—The earthing-up of Celery is best done in three stages at intervals of a fortnight, and when the plants are quite dry. Early plants should now be ready for the first earthing, after decayed leaves and side shoots have been removed. In small gardens each plant should be tied up lightly with a piece of raffia. Make the soil as fine as possible and place it firmly and carefully round each plant with the hands. If watering is necessary, a good watering of diluted liquid manure should be given a day or two before earthing-up. Care must be taken not to earth-up so as to prevent young leaves from growing freely. As a further precaution against slugs and Celery Fly, frequent light dustings of soot should be given in the early mornings when the plants are moist with dew. Continue to remove and burn leaves attacked by the Celery Fly, which is very prevalent this year.

PARSLEY.—There is a daily demand for this herb, and only those who have failed at any time to maintain a supply can fully appreciate the advantage of having an abundance at all times. Luckily, Parsley transplants readily, and this transplanting is the remedy for many causes of failure. At the present time failures may be made good by carefully thinning out the seedlings, and planting the thinnings 6 inches apart in the form of an edging to a sheltered border. Those who have frames to spare during the winter will do well to devote one or more to Parsley. In anticipation of this a bed or beds of the right size should be planted so that the frames may be put over them before severe frosts are experienced. A very little shelter will frequently save Parsley.

SPINACH.—A good sized plot of ground should now be sown with Round or Prickly Spinach for the winter supply. As this prefers light, warm soil in the winter a south border or other sheltered position should be chosen. On heavy, cold soils a good dressing of leaf-soil, burnt refuse, or other light material should be forked in previous to sowing. Sow thinly in rows 15 inches apart, and subsequently thin the plants to 4 inches apart.

TURNIPS.—Owing to the showery weather experienced, Turnips sown in July have made rapid progress. Where seedlings have fared badly another sowing should be made at once. This is a crop that cannot well be dispensed with, and every effort should be made to secure as good crops as possible. Only in the southern counties does it pay to sow later than the middle of August, as so much depends on the weather of the autumn months. If more roots are needed and late sowings are unavoidable, preference should be given to Early Snowball and Early Milan varieties, which grow quickly into useful size, but the best winter Turnips are Chirk Castle and Orange Jelly. Veitch's Red Globe raised in July has not infrequently kept good through the following winter.

CARROTS.—Make a sowing of Shorthorn varieties in cold frames which have been cleared of other vegetables, as the crop will be found most useful for winter and early spring use. Sow thinly in rows 9 inches apart and make the soil rather firm.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

SEASONABLE MANURIAL STIMULANTS FOR APPLES, PEARS, AND PLUMS.—About this time last year, when heavy crops of fruits were developing, I applied blood manure as a top-dressing with most marked results. The foliage became darker green and the fruits benefited. This year I could not obtain similar manure, but have secured a good brand of Peruvian guano, which I hope soon to use as a surface-dressing, lightly hoeing it in at once. A moderate amount will be applied, even where there is no crop, if I think that the trees stand in need of it. It will, in any case, assist in finishing up the growths and plumping-up the fruit buds for another season. This manure will induce increased vigour whilst the leaves are still capable of performing their functions.

EARLY APPLES AND PEARS.—The earliest varieties will now be ripening. It is a common mistake to allow both early Apples and Pears to remain too long upon the trees. Fruits so left never keep well nor ripen in the best condition. Where there is a good crop of any given variety of either dessert or culinary Apples, it pays well to thin the fruits when they are a fairly good size. Lord Grosvenor Apple, planted on warm or early soils, may

have its fruits thinned twice with distinct benefit to the specimens left to develop fully. As an early dessert Apple Worcester Pearmain may be treated in like manner; early-gathered fruits will not, of course, be of the best quality as regards colour, but the largest and best-coloured may, in this instance, be gathered first. When these early fruits are gathered they should be used as quickly as possible, but if they have to be kept for some time they should be placed in a cool store and in the dark, otherwise early shrivelling may take place. Rev. W. Wilks is one of the very best of early Apples; it is already colouring with us and is, as a consequence, being discovered by the birds. This is an Apple that it pays well to net in good time, and it is also one that may with distinct advantage be thinned early. In every case, if an Apple tree is bearing a good crop, it will pay to spend a little time in watering it during dry periods.

Cleaning the Fruit Room.—If this work has not been done already it must be no longer delayed. I like to use a paraffin and soft soap emulsion as a cleansing medium after the fruit room has been fumigated with sulphur. I am afraid there will be no difficulty this year in finding room for storing the crops. Do not attempt any painting, but the walls and ceilings may be distempered if necessary. Never store fruits on either hay or straw. Open lattice work makes good shelving. The floor may be strewn with clean sand to provide ideal conditions for all late-keeping varieties—of which every fruit will be needed in the coming winter.

FRUITS UNDER GLASS.

By W. J. Gyrse, Gardener to Mrs. Dearsley, Keele Hall, Newcastle, Staffordshire.

The Orchard House.—When the fruits have been gathered from them the trees in pots should be plunged outside and plunged up to the rims in ashes, or other light material, where they will set and ripen their buds of fruiting wood, as the case may be, in time for next year's forcing. Any unnecessary or overcrowded growths should be shortened or removed so that the fruiting wood may have full exposure to light and air. Peaches and Nectarines in pots will soon require attention; old soil may be removed from the roots and fresh compost provided, or, if needful, larger pots may be used. It is advisable to carry out this work while the leaves still remain, as then the trees quickly make new roots, which help the buds considerably. When the trees are potted they should be placed in the house, watered and syringed to prevent the foliage from flagging, and kept close for a few days. More air may then be admitted, and in a few weeks, when they are thoroughly established, the trees should be placed outside for the remainder of the season. Strong, rich, fibrous loam, old mortar rubble, burnt refuse, bone meal, and a little soot, will form a suitable compost without the addition of manure. Apple and Pear trees in pots may now be placed outside with advantage, but care must be taken to support the fruits by means of nets or ties, or they may be broken off during removal. An erection of poles and garden netting must be provided to protect the fruits from birds. Should the trees in the orchard house be unduly crowded, late Plums in pots—such as Coe's Golden Drop, the Imperatrices, Rivers' Late, and Jefferson, may be placed outside if they are sufficiently forward in a sunny position, where, from having full exposure to light and air, the fruit will finish better than under glass. All trees in pots will need liberal supplies of water, and should Pears suffer from neglect in this respect the fruits will be hard and gritty. It is advisable to give weak stimulants to trees that have been exhausted by bearing heavy crops. At the close of each hot day the syringe or garden-engine should be brought into use to cleanse and refresh the foliage.

Established Trees in Successional Houses.—The latest varieties of Plums established in borders, with fruits once thinned and swelling, require no artificial heat. They thrive best in a free circulation of air from early morning onwards, and the top ventilator should be open a little at night. In a house at Keele we have standard, half-standard and fan-trained trees which invariably give excellent crops of first-rate fruit under cool treatment. Syringing may be continued up to the time the Plums begin to colour, provided the water is free from lime. Atmospheric moisture after this stage can be produced by damping the paths, walls, and stems. Keep young shoots pinched, and tie in lateral growths required for extension. Old-established trees will need large supplies of water, and if the mulchings or top-dressings are washed out give liquid manure twice a week.

PLANTS UNDER GLASS.

By E. Harriss, Gardener to Lady Wantage, Lockinge Park, Berkshire.

Roman Hyacinths.—There seems to be an opportunity this year of obtaining some early-flowering bulbs of Roman Hyacinths, but it will be wise to order them early, as the supply will be very limited. The bulbs should be potted as soon as obtained. Provide a fairly substantial compost, or the flowers will be weak and of little decorative value. When potted, select them all in and cover the pots with ashes out of doors, and allow them to remain covered until growth commences; they should then be placed in a cold frame until required for forcing.

Early Narcissi.—It was said about to a considerable extent all bulbs required to produce flowers for cutting are planted in boxes or pots. Provide for the bottom of the boxes with rough potsherds, for this is all the drainage needed. The rest of the bulbs may be potted in 6-inch or 7-inch pots or planted in fibre in ornamental bowls or vases, and treated as advised for Roman Hyacinths.

Gloxinias.—As the old plants pass out of flower place them on a shelf in a dry, airy house and withhold water. Water must be given sparingly. Plants raised from seeds sown in the spring are now commencing flowering, and it is necessary to support them with a neat stake as the flowers open. With the best advice flowering pots may be allowed a cool cold frame atmosphere.

Mignonette.—A batch of this sweet-scented annual are welcome at any time, and by careful management they may be had nearly all the year round. A sowing may be made now for producing flowers in the spring. Use 3-inch pots and sow a few seeds in each, in a compost of loam, leaf-soil, sand, and finely crushed lime rubble. Water them in and plunge the pots in ashes in a cold frame. Shade them till the seedlings are well through the soil, then gradually bring them into full light and afford ample ventilation. Reduce the seedlings to three or four in each pot when they are large enough to handle, and at this stage they may be taken indoors and placed on a shelf in a cool house. The plants will need the support of stakes at an early stage. Allow them plenty of fresh air at all times, but avoid cold draughts. When they are well rooted pot them on into 3-inch pots.

THE ORCHID HOUSES.

By J. Collier, Gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate.

Laelia.—Such dwarf growing Laelias as L. longipetala and L. pumila, with its many varieties, are now commencing to grow afresh after a short season of rest, and as new roots are produced from the bases of the young shoots any necessary repotting should be attended to. These Orchids require liberal supplies of water during their season of growth, therefore the compost must be sweet and porous. Shallow pans, without side holes, form the most suitable receptacles, and these should be filled to one-third of their depth with clean crocks; press the compost moderately firm around the roots and leave sufficient space for a surfacing of living heads of Sphagnum moss. These Laelias grow well when suspended from the rafters of the cool house, and exposed to a reasonable amount of light and air at all times. Water should be applied sparingly to newly potted plants until they have become re-established, after which they should be given a plentiful supply until they have passed their flowering stage, but they should be kept moderately dry throughout their resting season.

Dendrobium.—Many of the species and hybrids of the deciduous Dendrobiums will now be completing their growth, and soon after the terminal leaf appears the plants should be allowed cooler, drier conditions, where they may have more sunlight and air. It is not always advisable to remove Dendrobiums from their growing quarters immediately they appear to have finished their growths; it is better, where practicable, to select a position on one side of the house, where more light and air can be admitted. Gradually expose the plants to morning sunlight for a longer and longer time, and draw up the blinds a little earlier in the afternoon. These Dendrobiums should not be allowed to become quite dry at the roots, therefore water should be supplied whenever the compost appears dry. Any sudden check at this stage will cause the buds to start into premature growth. After a week or two of this treatment the plants may be removed to a house where considerably less shade and a drier and more airy atmosphere can be provided. The new pseudo-bulbs may be loosely tied to neat stakes, or be allowed to assume their natural dependent habit. D. Wardianum flowers more freely and its flowers are seen to better advantage when the pseudo-bulbs are not rigidly tied up. Specimens still in vigorous growth should be afforded plenty of heat and moisture, and be treated according to their stage of development. Several other species of Dendrobium, including D. Phalaenopsis, D. superbiens, D. bigibbium, D. Goldiei, and others of this class are growing freely and require plenty of heat, sunlight and moisture. When affording water to these latter species the compost should be made thoroughly moist throughout, and allowed to become dry between each application.

THE FLOWER GARDEN.

By R. P. Brotherston, Gardener to the Earl of Haddington, Tyninghame, East Lothian.

Climbers.—These plants are often seen in a tangled, unmanageable state at this season, due to a considerable extent, to inattention during their earlier stages of growth, and to the lack of a due removal of superfluous shoots. But, even so, at this season an extra amount of labour is required to regulate shoots and keep them in that condition of trimness which is so essential to the pleasure of an ordered garden. There is far too little drastic pruning of climbers in spring, when, were old, overcrowded plants cut down to the ground, much trouble would be avoided, and the beauty of the plants themselves would certainly be greater.

Pelargonium.—Cuttings should be secured as soon as possible without lessening the amount of bloom in the beds or borders. As a rule the shoots for cuttings should be taken from parts of the plants where their removal will be unnoticed, and where it will benefit the plants by giving more space to those left. It saves a great amount of labour if each shoot is severed just below a leaf. The rest of the work needed to form cuttings should be proceeded with at once, and the finished cuttings laid out to dry in a shaded place for two days at least in order that the wounds may be healed before insertion. It is true that Pelargonium cuttings succeed better in small receptacles than in large ones, and better in pots than in boxes. But much depends on management, and if the boxes are stood on trellises to allow for perfect drainage during rain, the advantage where large numbers are grown is on the side of the boxes. Avoid overcrowding, especially where large-leaved varieties such as Paul Crampel are grown, but Madame Crousse need not have so much room. The Ivy-leaved section need not be propagated so early as the Zonal section, nor need the cuttings be dried to the same extent. Watering requires great care, as soils differ so much, but the less water is used until spring the better for the plants.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, AUGUST 13—
Royal Hort. Soc. Comm. meet.

WEDNESDAY, AUGUST 14—
Roy. Botanic Soc. of London annual meeting.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 62.4°.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, August 8, 10 a.m., Bar. 30, temp. 66.5°. Weather—Sunny.

Ormskirk Potato Trials, 918.

Potato wart disease continues its march of invasion into our fields and gardens, sometimes slowly, sometimes more rapidly, but all the time surely gaining ground. No means of evicting it when once it has found a footing are known. A chance discovery led to the belief that some Potatos, even when placed in the midst of the enemy, come unscathed through the ordeal, and give crops entirely free from the disease. The Board of Agriculture arranged to grow varieties on infested ground in order to test their power of resisting attacks. A badly infested piece of ground at Ormskirk, in Lancashire, in the midst of an important Potato-growing centre, was selected for the trials, and they were placed in the capable hands of Mr. John Snell, who has had charge of them ever since. The Ormskirk Potato Society, the Board of Agriculture, and Mr. Snell are all to be congratulated on the result. The work has led to the division of the existing varieties of Potato into immune and non-immune sorts. It has stimulated the raising of new varieties, each in its turn to be brought to the test, for it is doubtful whether in the course of ten or twelve years non-immune varieties will be able to be grown at all, and no one can therefore be sure that a new variety, unless immune, however good it may be in other directions, will be worth putting on the market. Immune varieties have proved, so far, completely and continuously immune, but there is room for others, for no really good cropping early variety commonly grown has resisted attack, and Arran Chief, King Edward, and all the Up-to-Date group fall victims. This year no fewer than 301 stocks are on trial at Ormskirk, and over 200 names are included. In order to make the results of the trials more widely known, the Food Production Department, under whom the trials are being conducted, this year arranged for a series of demonstrations to different groups of people interested in this important crop, and the whole of the past week has been occupied by them. It is too early to speak with certainty upon the immunity or otherwise of the new varieties. This will be better seen when the crop is lifted; but several have succumbed while others are apparently free. None of the varieties similar in growth and flower to Up-to-Date withstand attack, but all those like Abundance remain free, and we shall await the publication of the complete results with interest. Mr. Laurence Weaver, the Controller of Supplies in the Food Production Department, has several times expressed the hope that a branch of the Institute of Botany, which is foreshadowed, will be established at Ormskirk to carry on the work so well begun, and to extend it especially in the direction of eliminating names which are merely synonyms. Some light is thrown upon this difficult question by the present trials, but the differences which occur in the growth of the same variety from different sources make the recognition of synonyms no easy matter, and it is further complicated by the raising of new seedlings closely related in all characters to existing ones, but perhaps more vigorous with the strength of youth. The conditions under which the trials are carried out do not enable the full cropping capabilities of the different varieties to be ascertained, nor do they give any indication of the value of different varieties for different soils and climates; but for these purposes the trials are not designed; this is not their intention. Their first purpose is to test resistance to wart disease, and this test is the test to carry out well. Their next is to help in the determination of constant characters by which varieties can be recognised. This also they do, but it is doubtful whether it can be done by study in any one place of a plant changing in appearance so much according to source, season, and soil conditions. Careful study, accurate recording, and comparison of records from several sources will be needed before final judgment upon synonymy, and the facts which lead to the belief that names are synonymous, are established. But the accumulation of such observations will render easier the determination of what may be called basal characters.

The Manure Heap.

Further investigations* by Dr. E. J. Russell, in collaboration with Mr. E. H. Richards, mark an advance in our knowledge of the extent and conditions of loss of the fertilising ingredients of the manure heap. The authors find that the losses are at a minimum when storage takes place under anaerobic conditions, that is to say, when air is denied access to the manure. If manure be exposed to the air, the loss of dry matter is greater, and the more vigorous decomposition is attended by a higher rise of temperature than that which takes place when air is excluded. Proceeding to apply their results to the practical problem of storage of farmyard manure, Dr. Russell and Mr. Richards point out that the main sources of value of stored manure lie in the total nitrogen and in the ammonia which it contains. Therefore, the objects to aim at in a manure heap are the conservation of as much dry matter and as much ammonia as possible.

Tests carried out under varying conditions show that these objects are achieved by storage under anaerobic conditions at a temperature of about 80° F. In these conditions there is a considerable formation of ammonia and no loss of nitrogen, although a certain amount of dry matter is lost.

Unfortunately, these satisfactory results cannot be secured by storage in heaps. No matter how carefully the heaps may be constructed, there is always a loss of nitrogen and never an accumulation of ammonia. Therefore, the ideal method of storage would be the water-tight closed tank, to which access of air could be prevented. Needless to say, this method is not always practicable, and when it is not, the next best method must be practised. If the manure can be kept undisturbed under the beasts, there is less loss than if it is removed regularly and placed in heaps.

When it must be removed daily, there is nothing for it but to make the heap in the manner best adapted to keep down loss, that is to say, thoroughly compacted; and no less important is it to store the heap under cover. If left exposed to weather, the loss of dry matter is increased by 8 per cent., that of ammonia by anything from 10 per cent. to 33 per cent., and also a considerable loss of total nitrogen. Field experiments confirm the conclusion that manure stored under shelter is more valuable than that stored in the open, and show that even a slight shelter is beneficial.

Further experiments are being carried out with the view of determining how the knowledge obtained in the course of these investigations may be best turned to practical account—particularly by testing the value of a modification of the Belgian liquid tank, built under the animals, to receive the fluid part of the excreta.

Decrease of production and difficulty of supply make the problem of conserving the value of manure an increasingly important one, and it is to be hoped that these investigations will lead to a solution of the problem.

* *Journ. of Agric. Soc.*, VIII., Part 4, Dec., 1917.

HORTICULTURAL SCHOLARSHIPS FOR WOMEN.—The Food Production Department is offering ten scholarships, tenable at the Horticultural College, Swanley, Kent, for a course of commercial horticulture, of 38 weeks' duration, which will commence about September 19. The scholarships will cover cost of maintenance and tuition, and preference will be given to candidates over 21 years of age who are suitable for the positions of forewomen, instructresses, etc.

Only women who have had considerable experience in gardening and will undertake the work of food production for the duration of the war are eligible. Full information and forms of application can be procured from the Food Production Department, 72, Victoria Street, Westminster, but no applications will be considered which are received later than August 20.

War Items.—Lieutenant Robert Croux, proprietor of the Croux Nurseries, in the Val d'Aulnay, near Paris, has just been killed in the Champagne district.

—— M. Leon Barbier, Junr., of Messrs. Barbier and Co., Orleans, is now acting as interpreter with the American Army in France.

Appearance of Potato Disease.—The recent wet weather, as was expected, has resulted in numerous outbreaks of Potato disease "blight", and should warmer weather be experienced it is feared that very serious damage may be done. The Food Production Department has received reports of a large number of cases from Wales, where the disease seems to be much more prevalent than in any part of England. The English areas so far reported is more or less badly affected are Devon, Cornwall, Somerset, the Isle of Wight, Essex and Lancashire. Only one or two slight cases have been observed in Lancashire, where, as a rule, the disease does not appear at all until later in the season. Once the disease breaks out there is no absolute cure, although its spread may be checked by spraying with Burgundy or Bordeaux mixture.

Habits and Diseases of the Honey Bee.—The Board of Agriculture has appointed a Committee to study the life-habits of the hive bee with the object of improving the conditions under which bee-keeping is carried on in England and Wales, and to investigate the epidemic diseases of the bee, more especially the disease or group of diseases which pass under the name of "Isle of Wight" disease. The Committee consists of the Master of Christ's College, Cambridge University (Dr. A. E. Shipley, F.R.S.), Professor Punnett, F.R.S. (Professor of Genetics, Cambridge University), Dr. G. S. Graham Smith, M.D., Professor G. C. Bourne, F.R.S., D.Sc. (Professor of Zoology and Comparative Anatomy, Oxford University), Professor W. Somerville (Professor of Rural Economy, Oxford University), Mr. T. W. Cowan (Chairman of the British Bee-Keepers' Association), Mr. G. W. Bellamore, Mr. J. C. Bee Mason, and Mr. A. G. L. Rogers (Head of the Horticulture Branch, Board of Agriculture and Fisheries), with Mr. R. H. Adie as secretary. It is proposed to undertake the study of healthy bees at Cambridge and the investigations on "Isle of Wight" disease at Oxford. The Committee would be glad to receive specimens of bees suspected of suffering from "Isle of Wight" disease for examination and experiment. Communications on this subject should be addressed to Mr. A. G. L. Rogers, 4 Whitehall Place, London, S.W. 1.

Sydney Botanic Gardens.—Mr. Maiden's Report on the Botanic Gardens, Government Domains and Centennial Park, Sydney, N.S.W. for 1916 has only now reached this country. It is of unusual interest, because it records, though briefly, the celebration of the centenary of the Botanic Gardens on June 15, 1916. On this occasion the Director gave a short historical address, and speeches were delivered by his Excellency the Governor and other high officials. The Governor also declared three Vistas to be named: The Captain Cook Vista, the Sir Joseph Banks Vista, and the Governor Phillip Vista. A further ceremony was the laying of the foundation-stone of a Museum of Botany and Horticulture. As a consequence of the war the Report appears in a greatly abbreviated form, though the home activities of the establishment suffered little delay. A collection of Australian Orchids has been established in the open air. Rocks and snags have been used to accommodate tree-loving Orchids, as well as those found growing in rock-clefts. Shade has been provided by a Tea-tree (Leptospermum). A list of about 75 species included in the experiment is given, and very many of these are of the genus Dendrobium. The provision of seats seems to be on a more liberal scale than here at home. For example, one hundred new seats have been added in the "Government Domain," making a total of about 550, each being of sufficient length for four persons. Experiments with the outdoor cultivation of Palms have given some surprising results. Upwards of forty species have proved hardy in Sydney, many of which were previously supposed to require artificial heat.

Simple Methods of Keeping Fruits and Vegetables in a Fresh Condition.—Several simple and very interesting methods of keeping fruits and vegetables in a fresh state for considerable periods are discussed in a recent issue of the *Wealth of India*. It is stated that ripe (not over-ripe) and unblemished fruits may be kept for a month or so if immersed for a moment in water almost at boiling point, and packed into dry tins as soon as the moisture has dried off. The tins must be perfectly clean, and provided with close-fitting lids. Another method is that of packing sound fruits in powdered cork in boxes; the fruits must not touch each other, and there must be at least one inch of cork dust around each, with 2 inches at the bottom, sides, and top of the box. Sawdust has not proved a satisfactory substitute for powdered cork, but very fine sand, thoroughly washed and dried, and used in the same way as recommended for cork dust, has been found to be a good preservative for many vegetables and for all but very soft fruits. The method

(Photograph by C. P. Raffill.

Fig. 21.—Catasetum darwinianum. Three upper flowers male, two lower flowers female, the pouch occupying the anterior position in one and the posterior position in the other. (See p. 76.)

which appears to be especially suitable for preserving Apples and Pears consists in coating sound specimens with a warm mixture made by melting 1 lb. of resin, 1 oz. tallow, and 1 oz. beeswax together, but not allowing the mixture to boil. After having been rubbed over with whiting or precipitated chalk, a small pointed stick is inserted to serve as a handle, and each fruit is then dipped in the hot mixture. After dipping, the fruits are held in the air for a moment to allow the coating of solution to solidify. The handle is not removed, and all that remains to be done is to place the treated fruits on shelves or in boxes. When required for use the coating is cracked and peeled off. A point to be remembered is that when the fruits are exposed to the air, no matter which preserving method has been adopted, they must be used at once, as decay sets in rapidly.

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables in *Gardeners' Chronicle* for August 3, p. 42.)

SCOTLAND, N.

CAITHNESS.—Owing to an extraordinary storm on June 17 what promised to be splendid crops of fruits and vegetables were spoiled. The crops of every fruit promised to be far above the average of former years, and the month of May being very warm they were far advanced, hence the damage was more severe than it would otherwise have been. *W. F. Mackenzie, Thurso Castle Gardens, Thurso.*

BANFF.—Cherries and Plums promised well until the first day of May, when we had 10 degrees of frost, which wrought much damage, as the trees were in full bloom. *George Edwards, Ballindalloch.*

SCOTLAND, E.

ABERDEENSHIRE.—The fruit crops in these gardens are a good average. The continuous drought in the early part of the season prevented the earlier varieties of Strawberries from swelling sufficiently. *John W. Kinnear, Haddo House Gardens, Aberdeen.*

BERWICK.—The fruit crops in this district are a partial failure, probably owing to long-continued drought. The blossom in the early part of the season was extraordinarily good, but cold winds interfered with the setting of the fruit. Some varieties of Apples have set well, but Bramley's Seedling is very poor. *Peter Smith, Duns Castle Gardens, Duns.*

CLACKMANNAN.—The fruit crops in many parts of Scotland are very small. Gooseberries, in some districts, gave a fair crop, but Black and Red Currants were very poor. Plums, Apples and Pears are very scarce; Cherries, Raspberries and Strawberries yielded a fair average crop. It is believed that the east winds of April and May caused the failure, not late frost, as is so often the case. *Alexr. Kirk, Paton Street, Alloa.*

EAST LOTHIAN.—Apricots and Peaches have set full crops, but Plums, which blossomed quite as profusely, failed in a number of cases to set any fruit. Plums Monarch, Jefferson, Washington, Kirke's and Victoria are the only varieties bearing a crop. Only on young Pear trees are there any fruits, and Apple trees are only sparsely fruited. The Strawberry crop was spoiled by the drought, but other small fruits did not suffer. There is a larger crop of Figs than usual. *R. P. Brotherston, Tyninghame Gardens, Prestonkirk.*

FIFESHIRE.—This season we have the poorest crops of the larger kinds of fruits we have had for years past. Gooseberries, Raspberries and Red Currants bore abundant crops, and Black Currants yielded an average crop of good fruit. *William Henderson, Balbirnie Gardens, Markinch.*

—— I have seldom seen better prospects for good fruit crops while the trees were in bloom, but late frosts and cold east winds damaged the blossom. *D. McLean, Raith Gardens, Kirkcaldy.*

FORFARSHIRE.—The Apple crop in this district is most disappointing. During the early part of April there was a considerable quantity of blossom, but it did not develop, owing to several chilly nights about the end of the month. All kinds of bush fruits were small owing to lack of moisture. *Andrew McAndie, Ruthven Gardens, Meigle.*

KINCARDINESHIRE.—There was an exceptionally good show of flowers on most fruits this season, but owing to the long spell of dry weather the setting of fruit has been disappointing, especially in the case of Strawberries. Plums are, however, very promising, and Raspberries yielded well. *William Thomson, Urie House Gardens, Stonehaven.*

LINLITHGOWSHIRE.—The fruit crop is the poorest that has been experienced for many years. Cherries and Pears are almost complete failures, and the same could be said of Strawberries. Apples are slightly better, but still below an average crop. *John Highgate, Hopetoun Gardens, South Queensferry.*

MIDLOTHIAN.—The long-continued drought has had a bad effect on the fruit crops. Pears are few; there are fair crops of Apples on some trees, while the majority are bare. Strawberries were very small, but small fruits, on the whole, have been plentiful. *J. C. Scott, Oxenfoord Castle Gardens, Ford, Midlothian.*

—— All fruit trees showed more than a usual quantity of blossom, but during the flowering period a constant cold north-east wind prevailed, the result being the worst fruit crop experienced for many years. The soil is light and sandy, on gravel subsoil. *James Whytock, Dalkeith Gardens, Dalkeith.*

SCOTLAND, W.

ARGYLLSHIRE.—The fruit crops in this locality are much lighter than usual, chiefly owing to the abnormally wet autumn last year, which prevented the wood from being thoroughly matured. Again, when the trees were in blossom a cold east wind prevailed, with frost, causing the blooms to set badly. The Apple and Pear crops are very light; Plum trees on walls, protected with nets, are carrying a fair crop, but standard trees are almost fruitless. Small fruits (with the exception of Black Currants) were comparatively good, both in size and quality. Strawberries, which flowered nearly a month earlier than usual, suffered from the cold winds and late drought, and were not so large as usual. Raspberries were a bountiful crop. The soil is of a shallow, light nature, and if not heavily mulched the crops soon suffer from drought. *George Haig, Barcaldine Gardens, Ledaig.*

AYRSHIRE.—The fruit crops are most disappointing this season, especially Pears, Plums, and Strawberries. Ten degrees of frost on the mornings of April 14, 15, 16, and 17, did serious damage to Pears and Plums, which were in full blossom. Furthermore, cold nights, with a long spell of very dry weather and scorching sunshine during the day, right through the months of May and June, had a disastrous effect on all kinds of fruits in the open, especially Strawberries, the berries of which ceased to swell shortly after they were set. *D. Buchanan, Bargany Gardens, Dailly.*

—— The fruit crops, other than Red Currants and Raspberries, are all much under the average. The trees bloomed too soon, and caterpillars have been very destructive on Apple trees. No spraying was possible, owing to shortage of labour. *William Priest, Eglinton Gardens, Kilwinning.*

BUTESHIRE.—Most fruit trees bore a superabundance of blossom, but we had a period of east and north-east winds from the end of March until the beginning of June, sometimes reaching gale force, which had a serious effect on the crops. Apples on walls are almost a failure, and there are practically no Pears. Bush trees growing in the open flowered later, and the fruit set freely. All garden pests have been very prevalent, and have necessitated much labour and expense in spraying, otherwise the crops would have failed completely. Drought has not troubled us much, a period of three weeks in April being the longest spell of dry weather we had. *John J. Davidson, Ardencraig, Rothesay.*

DUMFRIES.—Black Currants and Strawberries were a little under the average this year, but Red Currants, Gooseberries, and Raspberries did well. Apple trees are bearing a very small crop, but of good quality. Pear trees are yielding a poor crop of low quality. Cherries are also under the average; when in flower the trees looked well, but the fruit set badly. We experienced low night temperatures for a considerable time, which caused the fruits to drop. The soil is light, sandy loam, with a gravel subsoil. *James McDonald, Drycholm Gardens, Lockerbie.*

STIRLING.—Apples, Pears, and Plums are poor crops. The weather was wet and stormy during the flowering period, though there were practically no late frosts. Small fruits were good. Strawberries promised well, but failed to swell satisfactorily on account of lack of rain. *J. D. Cunningham, Duntreath Castle Gardens, Blanefield.*

(*To be continued.*)

ON INCREASED FOOD PRODUCTION.

SPRING CABBAGES.

OF all Cabbages the spring batch is the most important. I have in these pages emphasised the importance of making at least two sowings. The first sowing should be made on July 30, on a finely prepared bed in an open part of the garden, which should not have been manured just previous to sowing. Another sowing should be made about August 10, on some sheltered spot, and the seedlings transplanted as soon as they are ready. For this sowing I recommend Sutton's April, Flower of Spring, and Wheeler's Imperial. The seeds should be sown in drills, thinly. Should the weather be dry, water the drills before sowing; subsequently keep the plants watered and protected from vermin.

As soon as the plants are ready they should be planted on a piece of rich ground, such as the site from which the main batch of Onions has been removed. On heavy soils it will be necessary to dig the ground, and give a top-dressing of soot. If the old Onion bed is not available and rich ground cannot be used, add 4 lb. superphosphate and 2½ lb. of kainit per square rod, and immediately after planting is done distribute 1½ lb. of nitrate of soda over each rod of ground. On light and rich soils it will suffice to work the surface with a Canterbury hoe before planting. Allow from 15 inches to 2 feet between the plants, according to the variety. Some growers place the plants 1 foot apart in the rows and cut out alternate plants before the Cabbages are large enough to spoil each other.

The seedlings, previously transplanted, should, if the weather be dry, be well watered the day previous to planting, so that each plant may be lifted with all its roots preserved and plenty of soil attached to them. Smaller plants may be left in the beds or dibbled in 4 inches apart to remain for the winter and be planted out in spring. After a severe winter there are often many vacancies, and these plants are useful for filling them. Frequent stirring of the soil is beneficial, as it admits air and keeps down weeds; it should be continued during the winter whenever the condition of the soil allows. Rich and stimulating food applied to Cabbages during winter may prove harmful, but after severe frosts are past the crop should be encouraged by applications of soot, nitrate of soda, liquid

manure, guano, and other stimulants, and by frequent hoeing. *Jas. A. Pave, Aldenham Vicarage Gardens, Watford.*

FLAGEOLET AND HARICOT BEANS

All growers of good vegetables will thank your correspondent, Dr. H. E. Durham, for his thorough and interesting article on this subject, and I hope that the Garden Committee at Wisley will take note of his remarks as to the lack of information in the Society's Report on Beans in 1910. There is one point, however, on which I should be glad of further information. I was under the impression, gained at many Exhibitions, that the term "Flageolet" was applied to a particular sort of Bean, of which no more than one or two varieties, having small pale green, kidney-shaped seeds, which are usually eaten after having been dried; but he uses the term as to such they were "Flageolets" only when eaten fresh, and he refers to "Haricots" when ripe and dry. Which is correct? I notice that he found the white-seeded Beans should be sown on the surface or very lightly covered. The majority of such Beans in our cold climate come on so late that they (probably) would not after become really ripe. Can he tell me which of the different varieties he would recommend as the hardiest, earliest and best cropper, and where I can get it? Prolong and Six Finger Mangetouts? Neither the Dutch Runner Beans nor those of the Japanese varieties which I have sown here seem, so far, likely to be of much value. *H. J. Elwes, Colesborne Park, near Cheltenham.*

HOME CORRESPONDENCE.

(The Editor do not hold themselves responsible for the opinions expressed by correspondents.)

MAGNOLIA GRANDIFLORA AS A STANDARD TREE.—While in Devonshire recently I visited amongst other places, the comparatively mild region of Salcombe and Kingsbridge, where tender plants and shrubs, which are dwarf in most other parts of England, are of astonishing size and vigour. On July 31 I spent a few hours at Bovey Tracey in the south-east of Devon, a sunny, but undistinguished garden part of the I suppose not to be a native road per se. I was amazed to see a large number of standard trees of Magnolia grandiflora, some 30 feet from the ground with expanded flowers and many buds. At Nice, early in November, I have seen the ground under a scattering with the bright red seeds of Magnolia grandiflora, but I have never seen ripe seeds on a standard tree in England. At Falmouth, a tree growing against a wall of a house was still covered with somewhat rain- and wind-dashed blossoms in February. The specimen at Bovey, however, may almost be expected to ripen its seeds this autumn. Perhaps some of your readers may have seen standard trees of Magnolia grandiflora in flower elsewhere; if so, it would be interesting to hear of them. The tree itself does not seem to be tender, but is generally supposed to require a south wall or fence. *Inquirer, Gardener.*

GOOD PRICES FOR HARDY FRUIT.—At the beginning of August I had the opportunity of reading a few recent issues of "Market Report" with respect to prices, and I found that Early Rivers' Plums were selling for "best Kent pack" as much as 15s. per half-bushel. This, I should think, will be almost a record price. It is without doubt a paying Plum to grow for market purposes, as it comes into use when early summer fruits are becoming scarce. As a rule trees of this variety have never failed to give a crop in this locality, but this year hardly a fruit is to be seen. Eckinville Apples are, however, a good crop, and the fruits keep well. Fruits of this Apple have been realising as much as 16s., whilst Beauty of Bath has sold at 20s. to 24s. per half-bushel. *James Hudson, Gunnersbury House Gardens, Acton, W.*

SOCIETIES.

SOUTHAMPTON HORTICULTURAL.

JULY 25 AND 26.—The Summer Show of the above Society, held on the Royal Pier, proved very interesting, but the attractiveness of the exhibits was much impaired by the lack of light in the Pavilion. Vegetables were the principal feature, and included two very fine collections shown by Messrs. SUTTON AND SONS and Messrs. TOOGOOD AND SONS, the first-named firm occupying 125 square feet, and the latter 40 square feet.

In the competitive classes for seven dishes of Potatoes there were four entries. In the premier class (prize, Gold Medal) Mrs. Wm. Wyatt, Esq., Mr. G. Edwards, Savernake Park, gained the first place, Mr. Owen Cattle, Ilfracombe, being second, and Mr. E. F. Hart, of Hoddesdon, Herts, third. Mr. Edwards secured second place in the Amateurs' and Cottagers' Classes, Mr. Cattle and Mr. Hart being third and fourth respectively. Messrs. H. Bryson and S. G. White, both of Eastleigh, and F. M. Vokes of Snodling, Ilfracombe, were successful exhibitors. Fruits were not plentiful, and the competition was confined to two exhibitors, Mr. Myers and T. A. Cotton, Esq., of Mr. Cattle's. The Medal Pears were shown by Mr. Myers.

Flowers in classes provided a good display, considering these are Lady Isobel flowers. Table decorations were not so good as usual, but two shown by Mrs. CLARK, of Basset, were the best of the three staged. Baskets, vases and buttonholes were numerous and effective. Cut flowers were staged by the nurserymen. Bonsai Carnations, shown by Messrs. A. E. Brown, Ltd., King's Acre, and Mr. J. J. Kirk, The Avenue, Southampton, both staged fine collections, the first-named firm securing the premier position. Messrs. Brown also secured the President's Cup. Mr. E. F. Hart was the most successful exhibitor of Perpetual Carnations. Special Prizes were awarded for collections of cut flowers, the efforts of the seven exhibitors in point of colour and shortness of stem. Mr. E. S. Ward, of Lyndhurst, was first.

Miscellaneous exhibits were included in Mr. J. J. Kirk's Group of Sweet Peas, a Silver-gilt Medal; Messrs. E. Lennard, Ltd., a Silver Medal for a spelt display; Messrs. Barr and Sons, and Mr. Wells, Silver Medals for collections of plants.

Most of the classes were well filled, and the Challenge Cup for Roses, the Rose Cup, and the Gold Medal of Southampton were awarded.

TRADE NOTES.

POTATO SPRAYING: PROPRIETARY MIXTURES.

THE Food Production Department states that Potato spraying is much more general this year in England and Wales than ever before, although the recent bad weather, commencing as it did with the date for the first spraying on a large part of the area, probably prevented many persons from doing the summer's desirable safeguard to the crop. The increased popularity of spraying, especially amongst small growers, has led to many enquiries reaching the Food Production Department as to the value of other proprietary mixtures similar to Burgundy mixture. The Department therefore wish it to be clearly understood that they are not in a position to recommend to the use of the growers any particular form or make of these mixtures. No doubt all are quite reliable, on the other hand reports as to serious damage to crops by the use of chemical preparations, on behalf of which the Department are unable to accept responsibility, have been reported to the Department. The only mixtures recommended officially are Burgundy mixture and Bordeaux mixture.

HORTICULTURAL SUNDRIESMEN AND CO-OPERATION.

A LITTLE while ago the question of admitting horticultural sundriesmen to membership of the British Florists' Federation was raised, and the committee decided that the rules of the Federation did not exclude sundriesmen; moreover, they agreed that if sufficient sundriesmen joined the Federation these should have their own sub-committee. As a consequence of these decisions invitations to meet at the Federation's offices, 55, Wellington Street, Covent Garden, were sent to the trade. The meeting, which took place on July 31, was a fairly representative one. Mr. F. S. Mansfield (Osman and Co., Ltd.) was voted to the chair, and Mr. Chas. H. Curtis (sec., B.F.F.) explained that the meeting had been called for the purpose of providing members of the horticultural sundries trade with an opportunity of discussing together the best means of co-operating for mutual interest and protection. He pointed out that their presence at the meeting placed them under an obligation to join the B.F.F. Quite fairly he suggested possible lines of action, such as the formation of a separate society affiliated with, or under the organisation of, joining the B.F.F. or other body and having their own sub-committee to deal with their special problems. The necessity for combination in every section of the horticultural trade was so obvious that there was no need to labour the point, but, as sundriesmen had not yet come in, he had called the meeting, as stated.

There was a general agreement that combination was essential, and though the question of "trading who were and who were not "horticultural sundriesmen" was raised, the general feeling was in favour of inclusiveness rather than exclusiveness. The next points were the best means of bringing the combination desired, and the strong representation and support in dealing with Government Departments, railways, etc. The formation of a separate society was considered inadvisable, and finally, after a free discussion, it was agreed "That this meeting of horticultural sundriesmen resolves to join the British Florists' Federation and have their own sub-committee." The principal speakers were Messrs. Jones, J. Pinche, J. Lambert, Wood, Jas. J. Weathers, F. S. Mansfield, Willis P. Bunyard and Biggs Keeling, and Hannibal. Letters expressing sympathy with the movement were read from various firms. A further meeting will be held early in September.

FLOWER-GROWERS AND FOOD PRODUCTION.

MR. C. H. CURTIS, secretary, British Florists' Federation, writes: "I feel sure your readers will be glad to know that returns from members of the British Florists' Federation prove conclusively that the principal growers of flowers for market are doing their best to food production during the war. Quite naturally, these growers desire to keep their flower-growing businesses in being, but the following figures show they have made great reductions in horticulture, both under glass and out of doors, and have directed their energies chiefly towards meeting the needs of the time. The 101 growers from whom returns have been received have holdings amounting in the aggregate to 1,646 acres 3 roods, of which area 1,296 acres 3 roods 17 rods is arable land, and 274 acres 2 roods 36 rods is under glass. In June, 1914, these growers had 1,235 acres 2 roods 25 rods of land, and 150 acres 1 rood 10 rods of glass under flowers, whereas in June, 1915, the areas under flowers were 825 acres 1 rood 14 rods and 97 acres 1 rood 34 rods respectively. In many cases flowers, notably bulbs, are inter-cropped and over-cropped with food crops. Further, where 82 acres 1 rood 1 rods of glass formerly were under flowers almost the whole of the area is devoted to food stuffs, the raising of cabbage seedlings, or vegetable and crops during spring, summer and autumn consequently the glass area devoted to food production this summer is really 111 acres 3 roods 12 rods. Of the arable land, the area under flowers has been reduced by about 730 acres, and the total area of land under food crops during the present year is approximately 2,799 acres, as against 2,015 acres in 1914. In short, while many of the best growers of flowers have always been large food producers in summer and autumn, they have found a further 730 acres under food production. Only those who know what plentiful supply such growers obtain by intensive cultivation can estimate how great an addition to the nation's food supply has been thus made. These few figures have been obtained for the use of an

: the Committees assisting the Food Production Department, and they furnish a good answer to those who are too ready to condemn flower-growers and flower production without good reason.

CROPS AND STOCK ON THE HOME FARM.

Methods of Farming.

In farming, as in many other industries, changes in methods or in the system of management occur with the changing needs of the nation. In no two counties are precisely the same methods of farming followed. Many counties may have much in common, but the details may be quite different.

In most of the southern counties corn and sheep are the important subjects, and especially is this so in hilly districts where the soil is thin, with a chalk subsoil; but in one county milk and cheese may be the principal products provided grass and water are plentiful; in other counties beef and Potatos may be largely grown. On some farms hay is an important crop, especially where the grass is rich and the situation near populous centres, and in the same counties vegetables may be grown extensively.

Where cereal crops and sheep are the chief aim a system of close-folding of sheep is usually adopted, for the benefit of corn crops to follow. For this method no breed is superior to the Hampshire Down, as the sheep thrive well when closely folded, and the lambs come quickly to maturity. There is no disguising the fact that this method of farming is becoming expensive owing to the increase in wages and in the prices of foodstuffs and material. Another serious set-back at present is the small demand for store lambs, owing to the lack of concentrated food-stuffs such as Linseed cake, which has no equal for fattening. Owing to adverse weather the prospect of satisfactory root-crops is not good. All these items are unfavourable to remunerative returns at a time when store lambs should be leaving the flocks for preparation for the butcher.

Satisfactory crops of Clover, Grass, Sainfoin, Rape and Cabbage are none too plentiful. The high price of Vetch seeds for autumn sowing will militate against a bountiful food supply in May and June next year; at one time Vetch seeds could be bought at 5s. a bushel, but this season the price will be nearer 40s. per bushel. The uncertainty of obtaining a desirable fixed price for Corn during the next few years, to compensate the risk of production; the scarcity of skilled labour, the high price of horses, the difficulty of obtaining feeding stuffs at a reasonable price, the scarcity of certain artificial manures, and the uncertainty of tenure consequent on the sale of so many estates, all have a tendency to depress the farmer and lead him to adopt changes in management.

The difficulty of successfully cultivating Turnips and Swedes, owing to the scarcity of labour and the high price of fertilisers, will set farmers wondering whether the close folding of sheep is still desirable. The management of sheep under this method is an expensive item. On a 350 ewe flock it is quite an easy matter to spend £2,000 annually, and with casualties occurring in an unfavourable season £100 can quickly be lost, and that without neglect or carelessness.

If large numbers of farmers were to dispense with sheep a mutton shortage might ensue. I do not suggest such a drastic change, but suggest a change of the type of sheep. Where an ample acreage of hilly land exists the Scotch, Welsh or Exmoor breeds could be kept; they need less attention than others, and succeed mainly on grass. An alternative scheme would be to improve the existing grass production and rear more cattle of approved breeds for the production of milk and beef. This method would reduce working expenses and add to the food supply of the nation. Even in a small way this suggestion can be carried into effect. Where milch cows are kept the method of buying a number of weaning calves, preferably of a good type of Shorthorn breed, is desirable. No phase of farming pays better than this when it is managed on good lines. Low-priced animals of mod rate quality never pay so well as those of a higher standard of quality; £50 is not an uncommon price for a newly calved heifer of the Shorthorn breed, especially towards the autumn, when preparations are made for a winter supply of milk.

As a hint to intending cattle-keepers, I may observe that pure-bred Guernsey cattle are in demand, especially pedigree strains. This is a highly desirable breed for butter production, and for general utility it is superior to the Jersey breed. Guernseys may not produce such rich cream as the Jerseys, but they give more, are hardy, and when their milking days are over they command higher prices from the butcher. An increase of cattle would reduce the labour in haymaking on pastures, which entail more labour than do rotation crops of Clover, Italian Rye Grass, Lucerne, and Sainfoin. These suggestions are made with a view to economy of labour without reducing the milk and beef supplies.

By reducing the labour entailed by close-folding a flock of sheep a largely increased acreage of cereals can be grown. In the place of sheep a judicious application of artificial manures would be needed to produce continuous Corn crops in the place of root crops.

Quite recently I inspected a hill farm in Wiltshire, of 2,500 acres, successfully managed on the lines suggested. From the success there achieved I am forced to the conclusion that a thorough knowledge of the soil and its requirements and a ready adaptation to changed conditions will yield good results.

Barley can be grown in the same field successfully four times in succession. This hint may be useful to those who need this cereal in small quantities on a limited acreage. It may occur to some that Wheat, which is the main cereal, cannot be grown thoroughly well without sheep, but the increase in cattle during the winter months will provide more animal manure, which, with the aid of Green Mustard ploughed in simplifies Wheat culture. Summer fallowing, followed with farmyard manure at the rate of 20 tons per acre, is the certain forerunner of a good Wheat crop, assuming the weather conditions are favourable, so the small farmer need not despair of a Wheat crop even without the aid of sheep.

Rape, grown 2 feet high, is a valuable green manure for Wheat if carefully ploughed in during September and the land is made firm by the aid of a presser, especially where the soil is light in character. I would also suggest an increase in the acreage of Potatos, which are a paying crop. *E. Molyneux.*

Obituary.

Captain A. E. Keeble.—His friends—and he had many among amateurs of horticulture—will learn with grief of the death, from wounds, on August 6, of Captain A. E. Keeble. Captain Keeble volunteered soon after the outbreak of war. He received a commission, and, after a period spent in this country, during which he acted as instructor in machine gunnery, he proceeded to the Front. Captain Keeble was 46 years of age, and unmarried.

Mr. T. A. Dorrien-Smith—We regret to announce that Mr Thomas Algernon Dorrien-Smith, whose fame in connection with the flower growing industry in the Scilly Isles is world-wide, died on August 6, at the Abbey, Tresco, Isles of Scilly, in his 75rd year. He was a keen lover of Daffodils, as well as an extensive cultivator of these flowers for the London and other markets, and for many years he was a member of the Royal Horticultural Society's Narcissus and Tulip Committee. Mr. T. A. Dorrien Smith was Lord Proprietor of the Isles of Scilly, and in that connection worked continuously for the betterment of his tenants. He not only maintained but added to the wonderful collections of sub-tropical plants made by his predecessors at Tresco, where, in a favouring climate, so many of these subjects luxuriate. Descriptions and illustrations of these famous gardens appeared in *Gard. Chron.*, Aug. 17, 1872, p. 1102; Nov. 22, 1879, pp. 657, 659, 661; and March 12, 1898, pp. 152, 153.

ANSWERS TO CORRESPONDENTS.

Books on Gardening: *M. H. H. Garden Work*, by W. Good (published by Blackie and Son), will meet your needs, but if you wish for a more comprehensive work we recommend *Thomson's Gardeners' Assistant*, in six volumes. You can obtain this from our publishing department, price £2 16s., post free.

Carnations: *H. G., Canterbury.* The stem of the Carnation plant you sent contained the mycelium of a fungus at the ground level, but it is not possible to name it. Spray with a weak solution of potassium sulphide.

Fruits Failing to Ripen on Fig Tree: *M. I. J.* Unless artificial heat is used to accelerate growth during the early part of the season the ripening of a second crop of fruits is hardly probable. If the instructions given from time to time in "The Week's Work" on the cultivation of Figs under glass are followed, there will be no difficulty in obtaining the best results your conveniences for growing Figs will permit.

Fuel for Glasshouses: *E. L. and G. M.* For full particulars apply to the Board of Trade (Coal Mines Dept.), Holborn Viaduct Hotel, E.C. 4.

Names of Plants: *H. C.* 1, Cassinia fulvida; 2, Griselinia littoralis; 3, Cupressus Lawsoniana; 4, Quercus rubra; 5, Juniperus virginiana; 4, Quercus rubra; 5, Juniperus virginiasiocarpa in gardens); 7, Veronica carnosula. —*J. B.* Lilium Martagon.—*J. W.* Lilium pomponium. — 1, *C., Carlisle.* Rondeletia gratissima, syn. Rogiera gratissima.

Peas: *W. H. M. and W. T.* There is no fungus present on the part of the plants submitted, but possibly the roots (which were not included) may have been attacked.

Pear Tree Slug Worm: *J. H.* The offensive slug-like creatures which are destroying the leaves of the Pear tree are the grubs of the Pear Tree Sawfly (Selandria atra). The pest is quite common in some districts, and attacks Cherry leaves as well as the foliage of Pears. The slug-like appearance continues for about six weeks, when an alteration takes place, the dark-green, slimy coat being thrown off, leaving a small, buff-coloured caterpillar. The sawfly lays its eggs just below the upper surface of the Pear or Cherry leaves at the end of May or during June, therefore the appearance of the slug-worms should be watched for in early summer, especially where there has been a previous attack. Two or three applications of quicklime, at intervals of a day or two, will kill the slug-worms. A suitable solution for syringing infested trees is made by mixing 2 lbs. of soft soap and 1 peck of lime with 30 gallons of water. The slime-free caterpillars descend and enter the ground, spin a cocoon, and remain therein all the winter, and from these cocoons the sawfly emerges in the following early summer; to prevent or greatly reduce subsequent attacks the surface soil beneath infested trees should be removed during the winter and burned or deeply buried. If the soil is removed to the depth of 4 inches, and a similar amount of rich soil is put in its place, a double benefit will be bestowed upon the trees.

Shrivelled Nectarines: *K. C. H.* The shrivelled appearance of the Nectarine fruits may be due to an insufficiency of water at the roots of the tree, or to over-cropping. Disease was not apparent on either of the fruits received.

Trimming the Leaves of Leeks: *H. M. S.* Two advantages are obtained by shortening the leaves of Leeks just prior to planting. There is less flagging, and, as it is usual to place Leeks in holes or in deep trenches, if the leaves were allowed to remain their full length many would touch the ground and be drawn into the soil by worms, and they would also be liable to attack by slugs.

LIFE AND LETTERS OF SIR JOSEPH D. HOOKER.*

It has rarely [illegible] and never to [illegible] me so much pleasure [illegible] as Mr. Leonard Huxley's *Life and Letters of Sir J. D. Hooker*, and I cannot think of any biography except, perhaps, that of Charles Darwin which taken in conjunction with such a remarkable book of travels as *Hooker's Himalayan Journal* may do so much to foster, encourage and guide any young man with a love of natural history. The author, who has been fortunate in having had at his disposal a great number of letters both from and to Sir Joseph Hooker, most carefully chosen and arranged by Lady Hooker, says of Hooker in his preface that "the busier he was, the longer and fuller his letters were likely to be, and he was always busy. How busy and how hard working, no one who did not know him intimately can conceive nor they read this book. The first thing that strikes one in that part of it which describes Hooker's early life, is the immense help and encouragement and assistance he received from his father, himself an extremely able and hard working man. His home life and education at Glasgow seem to have been, from a modern educational point of view, somewhat hard and strenuous, and many of his associates in the Glasgow University were not of his own social class.

It is probable that there can be no better experience for a young man commencing life than service in the Navy under such a commander as Sir John Ross, who led the Antarctic expedition, and in whose cabin Hooker worked for four years. Though Hooker's conditions of service on board the *Erebus* were not so hard as those of Darwin, as he never suffered from sea-sickness, yet the long and dangerous struggle during the ice navigation in the worst climate of the world, continued through three successive seasons, seems to have not only hardened his constitution, which in youth was somewhat delicate, but to have removed the heart trouble from which he suffered in early life, and which, as he says in a letter to his grandfather (Vol. I., p. 104) affected him to such a degree that he could never stand up before his fellow-scholars at school or college without violent palpitation, and when attempting to take part in a debate at college, always caused him to sit down in shame and confusion, however carefully he had conned his speech. In later life he seems to have overcome this nervousness to a great degree, and at the historic meeting of the British Association at Oxford, when the Bishop of Oxford made an unfair attack on Darwin, Hooker supported Darwin and Huxley in a most vigorous and effective speech. But he always got up his public addresses most carefully, and was never willing to speak in public without preparation.

During the first week of his voyage to India in 1845 Hooker's natural tact, manners, and modesty attracted the attention and secured the friendship of Lord Dalhousie, who attached him to his personal staff and gave him most valuable support during his journeys in India.

Hooker suffered grievously in later life from the [illegible] apathy, and parsimony then, even more than now, shown by the majority of our Cabinet Ministers and high officials on scientific subjects. His struggles to obtain the more pittance necessary to publish the results of his Antarctic journeys, though backed by the influence of his father, are described at length, and finally culminated, after he became Director of Kew, in his historic fight with Ayrton, 1870-1872. In this contest Mr. Gladstone, to his prestige Ayrton was, did not show to advantage, and Hooker, backed by the almost unanimous voice of the whole scientific world, came triumphant, though sorely vexed at the time by an intolerable attempt to treat him as a mere clerk, and even without the common courtesy which [illegible] duties to his office. Hooker [illegible] and [illegible] and [illegible] character, and when his back was against the wall [illegible] "Better to drink [illegible] than not to fight." His determination and [illegible] and shown in every [illegible] the [illegible] Thomas [illegible] off [illegible] to his explorations in the Himalayas, which were carried [illegible] hard [illegible] difficulties that only those who know [illegible] India can fully [illegible] The [illegible] to Morocco in 1871 in company with Ball and Maw. Though very little is said in the *Journal* to [illegible] Maw's part of the expedition is evident from the account published by Ball in 1873 that the difficulties of the first ascent of the Great Atlas would not have been overcome if Hooker had not been of the party.

Hooker's writings cover a period of no less than 71 years, commencing in 1839, when he was 20 years old, with a description of three new mosses in his father's *Icones Plantarum*, and ending in 1911 with five papers on Balsams, a genus of plants which occupied his attention almost exclusively during the last few years of his life. He retained his powers of sight, and his skill with the pencil and microscope almost to the end; and I well remember during my last visit to his house at Sunningdale in 1903, showing him at his request the revised proof of the article on the Beech in *The Trees of Great Britain and Ireland*, in which he took great interest. He read it through carefully without saying a word, as was his habit, and when he had finished was good enough to express his hearty approval, adding that he had detected two slight typographical errors, which no one else had noticed. Many of his papers are of too technical a character to appeal to any but botanists, but a number of them might well be collected and reprinted for the benefit of those all over the world who must constantly have occasion to refer to them.

Hooker's work as Director of Kew is a subject which will appeal specially to readers of the *Gardeners' Chronicle*, and is not dealt with so fully in the *Life* as it might have been. Sir William Thiselton Dyer tells us, in his masterly obituary notice of his father-in-law (Proc. Roy. Soc., 1912 that Hooker's personal hobby was the development and extension of the Arboretum which had been commenced by his father, and that he spared no pains in enlisting the aid of correspondents abroad and at home in enriching it; nor was he less anxious to have the specimens correctly named and the often deplorable confusion in their nomenclature cleared up. In 1902 the number of hardy trees and shrubs in this Arboretum, unrivalled in the temperate region of the world, amounted to about 4,500, and the skill exercised by two such eminently capable superintendents as Nicholson and Bean, in planting, pruning, and supporting the trees, makes the Kew Arboretum a model to all private arboriculturists. Another most valuable piece of work at Kew, to which I find no reference in the book, is the scientific and practical training which was given to the numerous young gardeners who pass through Kew, and whose admirable work both in public and private establishments all over the world, as I can personally testify, gives Kew the right to be called the most efficient and successful school for gardeners that has ever existed. The *esprit de corps* of Kew men finds expression in the Kew Guild, now presided over by that most distinguished and successful veteran, my old and valued friend Mr. Gammie. Though Sir Joseph and his successor, Sir William Thiselton Dyer, may have seemed to the less energetic and capable amongst them at times to be hard masters to serve, yet both at Kew and afterwards, wherever they went, the young gardeners were supported and encouraged. It is to be hoped that this training, which is among the most valuable functions of Kew, may never be lost sight of nor fail to receive the support of the Department in which the men serve.

Though, as a collector in the field, both of herbarium specimens and seeds, Hooker was indefatigable, I do not think, from what I have seen of him at Kew, that he admired plants for their beauty, or took much interest in their cultural peculiarities. He was much happier and more at home in the herbarium than in the garden. As a cultivator of indoor plants, Sir Joseph had a weakness not uncommon amongst those who have not in their youth learned the gardener's art by personal practice. He knew so many of the plants in their native countries, that he did not realise that the attempt to imitate the natural conditions of exotic plants as regards soil, water and temperature often leads to failure; whereas the practical gardener has learned by experience that these conditions, even when he knows them fully, which he rarely does, cannot be reproduced. If his orders, given when going round the Ranges had always been carried out, the efforts would sometimes have been disastrous to the plants; *vide* Vol. II., p. 179, where a story, for which I believe I am myself responsible, is given on this subject.

The Herbarium at Kew, founded by Sir William Hooker as his private property, grew and prospered under his son's personal superintendence and influence in a way that all who have worked there will know. A student could always get all he wanted in the shape of books, specimens, help and advice, more quickly and more certainly than in any other herbarium which I have ever had occasion to visit. Its Director resisted vigorously the attempts which were made, first by Owen and more recently by others, to remove part of the Kew collections to the British Museum. He realised that the living plants could not be studied without constant reference to the herbarium; though perhaps he did not as fully realise what many botanists even now do not seem to act upon sufficiently, namely, that the problems of variation cannot be solved unless the botanist works in conjunction with the gardener, and tests by

* *Life and Letters of Sir J. D. Hooker.* By L. Huxley. (John Murray, London.)

cultivation from seed the limits of variation in nature, and the extent to which characters are modified by change of environment and by hybridisation.

"No better proof can be given of the extraordinary interest and pleasure which botany can give a man in his old age, provided he retains his sight and brain power as Hooker did, than the way in which he took up the critical study of the Balsams. His letters to Gamble, Duthie, Gage, and others show the intense pleasure which these plants gave him, and the extreme difficulty of making out their characters, even though (as he said) (Vol. II., p. 336): "Happily my eyes are as good as ever and my hand as steady." He also took immense pains in trying to cut down to the very inadequate limit of twenty pages in article on the Flora of India which he prepared for the Imperial Gazetteer at the request of the Governor General. He says in a letter to Capt. Gage (Loc. p. 399) "Excuse my growl. I do love Indian botany: I long to see another Griffith."

As to the part which he took during the prime of life in championing the doctrine of evolution on conjunction with Darwin, Huxley, and Asa Gray, who were perhaps his most intimate friends and valued correspondents, I will say nothing. The subject is too great and too deep for me, and it has been so fully dealt with by abler pens in the *Life* of Darwin and Huxley that the omission of any further allusion here is permissible, more particularly as Prof. Bower has devoted a chapter of the *Life and Letters* to Hooker's position is a botanist. Neither will I say anything of his work in Sikkim as a geographer or as a geologist, in both of which capacities he has, though professedly an amateur, been honoured by those who, like Freshfield and the officers of the Tibetan Expedition, have testified to the accuracy of his geological observations and of his map of Sikkim.

Hooker's attitude to the honour which he received in 1877, of the K.C.S.I., after he had refused to accept the K.C.B. or the K.C.M.G., is given in some detail in Chapter xxxiv. His scruples were overcome by what he calls "a very pretty letter" from Lord Salisbury, and in writing to Darwin he said: "I had always regarded the Star of India as the most honourable of such distinctions: it is very limited (to 60 K.C.S.I.'s), is never like K.C.B. given by favor or on personal considerations, and it has a flavor of hard work under difficulties, of obstacles overcome, and of brilliant deeds that is very attractive. Assuredly I would rather go down to posterity as one of the 'Star of India' than as the holder of any other dignity whatever that the Crown can offer."

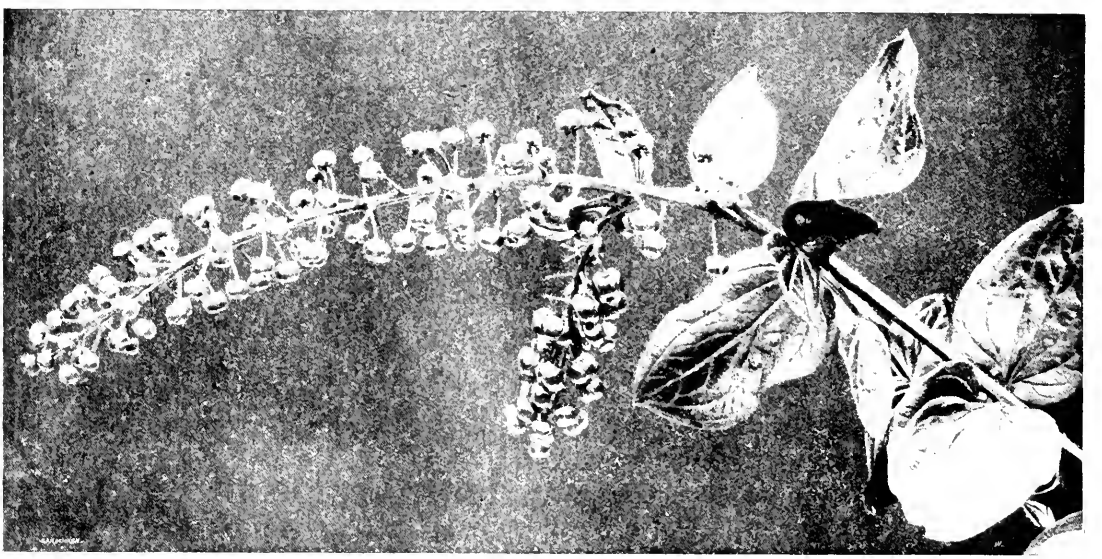
Hooker was fortunate in his two marriages, his first wife having been an exceptionally gifted woman who was able to help him greatly in his work. Lady Hooker, who survives him, has been of the greatest assistance to the author in furnishing him with materials and personal information, and the work she has done in this way is gratefully acknowledged by Mr. Huxley in his preface. *H. J. Thwes.*

TREES AND SHRUBS.

CORIARIA TERMINALIS.

When in fruit, Coriaria terminalis is a very graceful and attractive plant, especially the months of July and August. The individual blooms of this variety are larger than those of the type.

Another well-marked variety is rubens, which, like the preceding, was introduced from China by Mr. E. H. Wilson. When shown at the meeting of the Royal Horticultural Society on May 9, 1905, it was given an Award of Merit, but at the following meeting, on May 23, it received the higher honour of a First-class Certificate. The variety rubens differs so markedly from the type that some people consider it worthy of specific rank. In C. m. rubens the leaf stalks and young stems are heavily tinged with purple, and this colour occurs to a lesser degree in the foliage. The most prominent feature is, however, the flowers, which are somewhat later in expanding than those of the type, and of a beautiful rosy-red colour. In *Trees and Shrubs Hardy in the British Isles*, Mr. Bean refers to this Clematis as being probably the most beautiful climber distributed in the twentieth century. I do not suppose anyone will question this opinion, especially when the best form is considered, but individual plants do not appear to



[*Photograph by C. P. Raffill*

FIG. 22.—CORIARIA TERMINALIS: FRUITS GOLDEN-YELLOW.

form which produces racemes of yellow fruits. The species was introduced to England in 1897, but was collected in Sikkim nearly 50 years earlier by Sir Joseph Hooker. In the southern counties it is quite hardy, and flowers and fruits each year on the annual growths which rise from 3 feet to 4 feet high from the woody root stock. In the generally accepted sense of the word, Coriaria terminalis is not "shrubby," but its woody base brings it under that description. When fully developed, with their surrounding petals, the fruits may be almost half an inch across, consequently a finely grown and heavily fruited plant is invariably admired. The yellow fruited form is the older introduction; the black fruited variety was introduced by Mr. E. H. Wilson in 1908. *K.*

CLEMATIS MONTANA AND ITS VARIETIES.

Clematis montana, introduced from the Himalayas in 1831, is generally recognised as one of the most beautiful of spring-flowering climbers. It would be inappropriate to refer to the species at the present season were it not for the fact that the variety Wilsonii flowers during the be of equal merit. The same may be said of the type, of which a selected variety known as grandiflora is in cultivation, and, according to *Hortus Veitchii*, flowered first at Exeter in 1844.

All these varieties of Clematis montana, as well as the type, are vigorous climbers, and valuable for covering arbors, pergolas, and verandahs. They are also very effective when allowed to climb into a neighbouring tree from which the long, gracefully disposed shoots may droop in festoons. *W. T.*

PLATANUS ACERIFOLIA SUTTNERI.

The beauty of this tree is such that many are tempted to plant it after seeing a specimen in good condition, but more often than otherwise only small or young trees are to be seen. It is not nearly so vigorous as the ordinary form of the London Plane, as some leaves are wholly white, or nearly so; others are variously and extensively splashed with white, or the latter may be the ground colour, marked with spots, blotches or large patches of a dark green. I have seen a fine specimen, about 25 feet high, completely disfigured by the fungus Gloeosporium nervisequum. The green type is liable

to much injury from the same fungus, but this variegated form shows the effects most conspicuously when the white portions are turned brown. The finest tree of Platanus acerifolia Suttneri I have seen is in the grounds of Holland House, Kensington, where it stands 35 feet high, and is well furnished with branches and faultless, strikingly variegated foliage. Mr. Dixon, the gardener, is fond of trees and shrubs and tends a large collection on this fine old London estate. *J. F.*

ORCHID NOTES AND GLEANINGS.

CATTLEYA HARDYANA THE KNOWLE VARIETY.

IMPORTED originally as a natural hybrid between C. Warscewiczii and C. Dowiana where the first specimen of C. Hardyana shown by the late Geo. Hardy, Esq., was awarded a First-class Certificate at the Royal Horticultural Society's meeting on August 11, 1885. Since that time some thirty varieties have received awards at the hands of the Orchid Committee, some of which have been unnamed. The earlier varieties were dark and more or less approaching C. Warscewiczii, but later petalled forms have appeared among home-raised seedlings.

A splendid flower of C. H. The Knowle variety, one of the finest dark varieties we have seen, is sent by John Hardy, Esq., The Knowle, Malpas, Cheshire. The plant is from his collection of orchids and received a Certificate at a show of the Manchester and North of England Orchid Society five years ago. The flower sent is 6 inches across, the sepals and petals bright rosy-mauve with fine crimson ground colour showing through to form the veining and conspicuously on the midribs of the inner parts of the segments. The large crimped-edged lip is ruby-red with a purple shade, the colour being continued at the edges of the side lobes. The base of the lip is veined with chrome-yellow, and on each side are patches of lighter yellow.

LAELIOCATTLEYA CONTRAST.

THE first flower of this pretty new variety between L.-C. bella alba L. purpurata C. labiata and L.-C. Cassandra Rex L. purpurata C. Mossiæ is sent by the raisers Messrs. Sanders, of St. Albans. The flower inherits the good shape and substance of the Cattleya parents, and is free from the defective folding back of the petals seen in many hybrids derived from L. purpurata. The title of "Contrast" is well chosen as the effect of the richly coloured deep violet purple labellum, backed by the broad pure white sepals and petals, is very striking. Although the colouring of the lip presents, at first sight, a uniform shade, closer examination shows that the bright effect is produced by a mixture of dark ruby-red and violet.

MR. CARRINGTON LEY'S HYBRID POPPY.

MANY years ago the late Rev. C. Wolley Dod gave me a plant of this hybrid Poppy, whose parents are, I understand, Papaver orientale and P. rupifragum. It is a good perennial with smaller flowers than those of most of the other forms of P. orientale, and of a fairly good scarlet colour. The foliage is less vigorous than that of the Oriental Poppies, but otherwise the plants show little trace of descent from P. rupifragum. I do not know whether to consider it an advantage or not, but this Poppy does not produce seeds, whereas P. rupifragum, like some others of the race, seeds too freely, and reproduces itself so abundantly as to become a weed in some gardens. Mr. Carrington Ley's Poppy has never seeded with me; at least, it has not produced any perfect seeds, although it forms seed capsules. It grows about 3 feet high, and gives annually in May and June a succession of brilliant, cup-shaped flowers. *S. Arnott.*

THE ALPINE GARDEN.

CAMPANULA KOLENATIANA.

THE stately but extremely variable Campanula Kolenatiana, a native of the Caucasus, was figured on page 25 and 24 was shown by Messrs. R. Lynch and Sons, Ontwell, at the meeting of the Royal Horticultural Society held on June 18 last, when it was given an Award of Merit. It is of tufted habit, with ovate-lance leaves on slender stems 6 inches to 9 inches long. These, as well as the stems, are covered all over

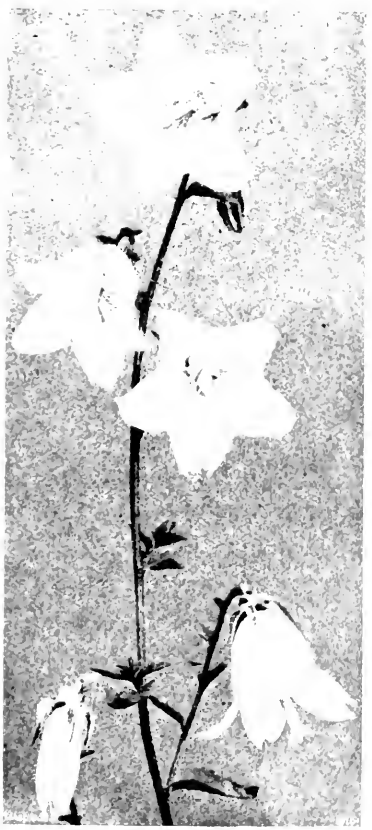


FIG. 25.—CAMPANULA KOLENATIANA: SHOWING PART OF AN INFLORESCENCE.

with short stiff hairs, which give an impression of roughness when handled. Numerous stems are produced and they grow about 1 foot high, bearing a few flowers, the lower being shortly stalked, while the upper ones are quite sessile. The branches from near the base upward, each branch bearing one or two large, purplish-blue flowers 1 inch in diameter. The flowers are pendent, with recurving lobes which have a deeper shade of colour. There is also a pale-flowered form in cultivation. C. kolenatiana is a native of the Caucasus, where it grows in rocky situations. Seeds were received from Tiflis Botanic Garden in 1910, and plants raised from them flowered in June of the following year. The species is a decided acquisition for the rock garden or border, as it grows freely in half-shady situations if planted in rich, light soil. Seeds are produced in abundance and germinate freely. C. Raddeana is a close ally, but is smaller in all its parts, has more numerous flowers, and is without the stiff hairs of C. kolenatiana. *W. I.*

CYANANTHUS LOBATUS.

FEW plants receive so much admiration as a well-grown specimen of Cyananthus lobatus. It is a Himalayan species, and one of the choicest Alpines we have for flowering late in the season. There can be no diversity of opinion as to the beauty of this Cyananthus. It forms a trailing mass of dainty foliage, with an abundance of large, blue flowers, which remind one of small flowers of Vinca minor.

C. lobatus often baffles the cultivator and losses of plants are too common during winter, when there appears to be a great risk of the fleshy roots decaying in cold, damp weather. On the other hand, excessive drought in summer and autumn cripples the plant seriously, and when this happens it may succumb in the winter months even where there is no excess of moisture. The most successful cultivators of C. lobatus grow it on a low terrace with a north-west exposure, sheltered from strong sunshine in summer. Leafmould, sand, a little loam, and a small quantity of peat provide a suitable compost for this species. The plants I have in mind were watered well in summer and early autumn, but in late October were covered with a sheet of glass to protect them from the rain and snow. *S. Arnott.*

ON INCREASED FOOD PRODUCTION.

ENDIVE.

FOR the summer autumn, and winter use, Endive is extremely useful. When well blanched it is one of the best flavoured salad plants we have, and at the same time it presents an appetising appearance on the table. For latest crops seed may still be sown, but the most important crop is obtained from a June sowing. The plants are usually planted out to succeed some crop for which the soil has been well prepared, such as Peas, Onions, or Potatos. A well-drained position should be chosen. The rows should be about 15 inches apart, and the plants 12 inches apart in the rows. When lifted from the seed-bed the seedlings may have their roots and foliage cut back about one-third of their length, as this makes planting easy, and the plants recover quickly.

There are several methods of blanching Endive; but the curled-leaf varieties I prefer to use an inverted pot over each plant. All light must be excluded to get the best results. Endive may also be covered by slates or mats, and have the tips of the leaves tied in to secure blanching; this latter is the easiest way, and for the round-leaved varieties I prefer it to other methods, as I think the flavour is improved thereby; but plant must be tied up only when they are dry and the weather is fine. The round-leaved varieties will afford an abundance of good salad plants until the end of October in the open, and to an allotment holder there is no more easily grown salad for autumn use. A succession should be maintained by tying sufficient plants when the weather is fit, each week, and allowing ten to fifteen days for blanching.

Where protection can be given, Endive may be had in good condition until the earliest Lettuces are fit to cut. If frames are available the plants should be lifted in October and placed fairly closely together in sandy soil, after removing any decaying foliage. If the weather is dry, a good watering will be beneficial. Frame treatment is similar for both curled and round-leaved varieties. Blanching in frames can be done by covering the plants with dry elm leaves three weeks before they are wanted for use, or by covering the lights with mats. *H. L. Lavender.*

THE MARKET FRUIT GARDEN.

THE drought was very effectually broken by the rainfall of July. Rain fell on sixteen days in my garden, though on three of them there was not enough to measure. During a brief thunderstorm on the 17th over half an inch of rain fell in less than half an hour, whilst a prolonged storm on the 20th gave 1.35 inch of rain. The total fall for the month was 3.95 inches, which is above the average. All vegetation has benefited greatly from the welcome moisture. Fruit trees have made a lot of growth—particularly noticeable in the secondary shoots on cordon Apples summer pruned at the end of May—and now present a very different appearance from that shown after the early summer plague of caterpillars. Trees then practically stripped of leaves are now refurnished and are making some progress. The rain came in time to assist the swelling of Plums, with the result that some extra fine samples of Early Rivers' and Czar have been sent to market. Late and even mid season Apples are also much improved in appearance, and now promise to be large and clean. Early varieties, on the other hand, were too far developed to benefit to any extent, and there are many "scrumps" (small, misshapen fruits) and "drops" amongst these. This has been very noticeable with Beauty of Bath, a variety always liable to drop badly. However, in a season of such scarcity, any Apple has a market value, and "scrumps" and "drops" have sold at higher prices than are often received for first rate samples.

REMARKABLE PRICES.

Before these words are in print the prices of Apples may have been officially controlled, but, at the time of writing, only a few common varieties of Plums (chiefly the Bush Plum, or Mogul, largely grown in Kent, and the Pershore, or Egg Plum) have been restricted. Meanwhile growers fortunate enough to have crops of early varieties of Apples and Plums have been enjoying a pleasant little harvest. A few of my Early Rivers' Plums realised the extraordinary price of 46s. gross per half bushel of 28 lbs., whilst the best Beauty of Bath Apples sold at 35s. per half-bushel of 20 lbs. Previously I have never sold Early Rivers' above 8s., and they have been as low as 1s. 9d., whilst Beauty of Bath has never been above 10s., and that was only in 1917. 2s. 6d. to 6s. being the range of prices before the war.

Such prices show in striking fashion the need of the public for fruit, for they have been willing to pay 2s. per lb. for Plums and 1s. 3d. per lb. for Apples retail. No doubt they were influenced by the fact that the Government commandeered most of the soft fruits, and by the prospect of the same thing happening soon in the case of Apples. But the great fact indicated by the high prices is the phenomenal scarcity of fruit, this probably being the most disastrous fruit season on record. Markets are exceptionally empty, and many orchards carry no fruit at all, so that the owners are unable to reap the benefit of the high prices—facts which should be remembered by those who are inclined to believe that growers are making a fortune in war-time. As a typical example of shortage I may mention my crop of Mr. Gladstone. Last year 29 of the oldest trees yielded 110 half bushels, or nearly four to a tree. This year the entire crop from these and many younger trees went to market in 9 half bushels.

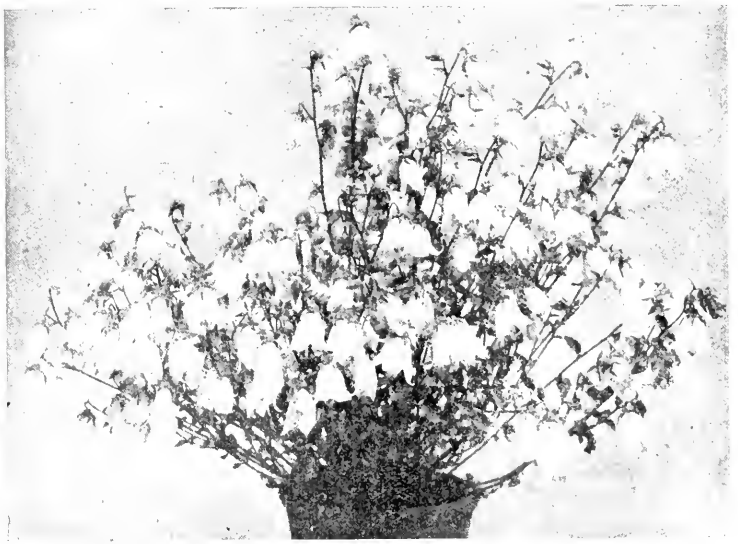

FIG. 24.—CAMPANULA KOLENATIANA.—FLOWERS PURPLISH BLUE.

(See p. 67.)

A GOOD EARLY APPLE.

One of the fairly modern varieties that has "made good" as a market Apple is Early Victoria. This is a large, green, cooking Apple which becomes big enough for market before the end of July, and it has the further merits of being very prolific and coming into bearing at an early age. I am confident that it is going to be a success here, where only a limited number of varieties thrive really well. The trees, half standards, presumably on Crab stock, were planted on some very poor, light land in the autumn of 1916. A note made at the time states: "Early Victoria very weak and covered with fruit-buds. Little chance for them, I fear." They now look thoroughly healthy and vigorous, and have borne a moderate crop in this, the second season after planting. The fruit would not have been allowed to develop had not the trees been making such strong growth at the same time. It was gathered on July 25, and sold well. Should this variety maintain its healthy character it will prove very valuable, for we need a big cooking Apple to market early. *Market Grower.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

WINTER ONIONS.—Now is a good time to sow seeds of this important crop. In many instances sowings are made too early, and much of the crop runs to seed in the next season; moderate-sized plants are the best for transplanting in the following spring. Tripoli Onions are often allowed more room than they really need: the rows may be sown 9 inches apart, and the seedlings, when transplanted in the spring, placed 6 inches apart in rows 12 inches apart. Red-skinned Onions have the best constitutions, and are not so liable as the white varieties to be attacked by mildew. On the other hand, white varieties are the earliest, and for this reason alone a few should be grown. No fresh manure should be used now, but a piece of good, open ground should be selected for the seed-bed. A good dressing of wood ashes should be given the ground, and soot ought always to be used freely, as it acts as a fertiliser, and prevents attacks by the Onion maggot. Giant Red Tripoli, Lemon Rocca, and White Leviathan are all good and reliable Onions, while the newer Autumn Triumph should certainly be given a trial for its excellent cropping and keeping qualities.

TOMATOS.—It is important that an early start should be made with the plants that are to produce fruit in quantity during the late autumn and winter months. Those placed in their permanent quarters much later than the present time may grow strongly, but refuse to flower or set fruits properly, and in any case it is the wisest course to be rather too early than late. Pot culture is best for winter supplies. A high temperature and moist atmosphere prove fatal to a good set, but if air is admitted freely, a buoyant atmosphere maintained in damp weather by the aid of fire-heat, and the flowers fertilised when the pollen is dry, a good set of fruits should result. A night temperature ranging from 55° to 60°, with an increase of 5° in the day-time, is ample for winter Tomatos. Plants in full bearing should be top-dressed with some approved fertiliser. Guard against a stagnant atmosphere, or disease is almost certain to make its appearance.

GENERAL INSTRUCTIONS.—As soon as Peas, early Potatos and other crops are over, clear away all haulm and other refuse. Where it is possible to have a fire all weeds and other rubbish should be burnt and the ash returned to the ground. Frequently stir the surface soil with the hoe between all growing crops, as nothing accelerates growth more than the admission of air to the roots. Attend to the early thinning of all winter crops, such as Turnips and Carrots, and continue to plant Savoys and other green crops for winter use, so that no plot of ground remains idle.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to SIR JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

CLEANING OPERATIONS.—At the present season, when very little repotting requires to be done, all the spare time should be devoted to cleaning the plants, pots, and houses. Cattleyas, Laelias, and other hybrids should have their leaves sponged, and any scale insects detected on the rhizomes removed by means of an insecticide applied carefully with a small, moderately stiff brush. This operation needs special care; much damage may easily be done by an inexperienced hand, which may not become apparent until later, when the rhizomes turn black and decay. Where insects are not present the plants should be merely sponged with a weak solution of soft soap, dissolved in tepid rain-water. The houses should be occasionally fumigated as a preventive measure. Periodical sprayings overhead with a solution of Quassia extract at the rate of half-a-pint to 5 gallons of

tepid rain-water will, in most cases, keep insects in check. Spraying should be done on fine afternoons, when evaporation is likely to be rapid and harm will not be caused by the Quassia-water remaining too long in the centre of the partly developed growths. The above treatment applies to all Orchids. At this season there are large numbers of young shoots, in various stages of development. Support should be given to any that are likely to bend over, by loosely tying them to small neat stakes, which may be removed after the growths have attained their proper size and strength.

Watering, Ventilation, and Heating.—Plants that are in full growth and well rooted into the compost require more liberal supplies of water at the roots just now than at any other period. This especially applies to such genera as Cypripedium, Calanthe, Phaius, Cymbidium, Vanda, and Angræcum. Although the atmosphere must be moist, a little ventilation should be allowed in the warmest houses in fine weather. The middle of August is a favourable time for the overhauling of the hot-water system, as fire-heat may be dispensed with for a few nights even in the warmest houses. During this time damping down should be reduced, the plants kept drier at the roots, and the blinds drawn up an hour or so earlier in the day than usual. The boilers and pipes should be emptied and cleared of all sediment. Thoroughly cleanse the flues and chimneys, and see that everything is put in working order ready for the winter season. Towards the end of the month a good many points, especially Odontoglossums, deserve quite exacting. Sufficient quantities of potting materials should be prepared ready for use.

THE FLOWER GARDEN.

By R. P. Brotherston, Gardener, and H. Lane, Haddington, Tyninghame, Lady L. Ho.

Roses.—Considerable attention will be required to keep Climbing and Rambler Roses tidy. Some of the latter have a tendency to throw new shoots at the base of the flower trusses, but all these should be cut out as soon as observed. The long, flowerless shoots of the previous year will require attention too, not only to tie them in where needed to fill spaces, but in thinning out to the right number. While as few ties as possible to save work later and the growths are rearranged. Roses that have finished flowering, such as Appe Bessons, should be pruned, or rather thinned, so that the trees are no longer burdened with useless growth.

Rock Garden. Interest in the rock garden is now on the wane. Now that less attention must be taken to preserve a good appearance the growth should be rigidly curbed, not by cutting in the offending plants with a knife, but by plucking pieces away by hand, so that no obtrusive trimness shall follow. Weeds should be removed while still small. Ground not fully covered with plant growth should be neatly mulched with very finely sifted soil enriched with soot or pigeon manure, or both. Thickly-matted plants should have portions removed here and there, and if the parts laid bare are filled with compost a better display of flowers will be secured next year. This advice applies to such plants as Hutchinsia, mossy Saxifragas, and others of similar growth. Autumn-flowering Cyclamens will be greatly assisted if a portion of the upper soil is removed and fresh material is added. Seeds may now be sown, and if young plants are kept in reserve be in no hurry to plant them until growth commences, and, as a rule, it is best to reserve them until they are quite strong before planting them in the rock garden.

FRUITS UNDER GLASS.

By W. J. Grigg, Gardener to Mrs. Dempster, Keele Hall, Newcastle, Staffordshire.

Peaches and Nectarines.—The trees in early houses have nearly finished their growth, except for a few shoots of breast-wood. These should be removed at once, as no advantage is gained by retaining wood that is not required for bearing fruit next year. When the trees are pruned the young shoots should be tied in from 4 to 6 inches apart, covering the branches at the base, in the case of older trees, as much as possible. The borders should be well watered once a fortnight, and the trees syringed every evening when the weather is warm. Make preparations for lifting any trees which are not in good condition, and give them fresh soil. In the case of very old-established or exhausted trees, commence this work before the leaves begin to fall; during the next few weeks the trees should quickly form new roots and take hold of the fresh soil before the cold weather sets in. No manure will be required at present, turfy loam is used, with a liberal sprinkling of mortar rubble or chalk and a little charcoal or wood ashes. Prepare the soil under an open shed; it is important that it be in a friable condition when rammed around the roots.

Trees in Mid-season Houses.—As soon as the last fruit is gathered from trees in mid-season houses the same procedure should be followed as advised for early houses in a previous calendar. Where the trees are confined to inside borders, be careful to see they do not lack moisture at the roots. Give trees that have carried heavy crops of fruit a good soaking of liquid manure, soot-water and lime-water, and, by way of a change, a light sprinkling of concentrated manure.

Late Crops. Expose the fruits on late trees to [illegible] the influence of the sun, as there is still plenty of time for colouring, and a little shade will assist [illegible] Do not thin [illegible] [illegible] suitable material without delay, but [illegible] the borders to become absolutely dry [illegible] Keep a [illegible] the trees, and [illegible] no longer required [illegible] gentle syringing [illegible] [illegible] Before the use of the syringe [illegible] fruits begin to [illegible] and afford [illegible] to extend the season is [illegible]

THE HARDY FRUIT GARDEN.

By [illegible] Head Gardener at Arisaig House, Arisaig, W.

Outdoor Fruiting Vines. Under favourable [illegible] especially if sheltered by [illegible] outdoor Grapes should now [illegible] quite ripe. Some amount of thinning [illegible] necessary, and care is [illegible] old [illegible] removed. It is only by [illegible] the vines [illegible] that good results can be obtained. [illegible] abundant growth, prevent any [illegible] foliage, and pinch the shoots at [illegible] beyond the bunch of fruit. It is a good plan to be on the safe side and always dust the vines with sulphur to guard against attacks of mildew. Newly planted vines or those not bearing a crop, should be encouraged to make strong, healthy growth; a few vigorous shoots are much to be preferred to many weak ones. Some of these growths, by ties so as to prevent any injury from storms. Unless they are in quite dry positions it will scarcely be necessary to water the vines, though those planted during the spring may need an occasional soaking.

Summer Raspberries and Loganberries.—As soon as the fruits have been picked and ready the old fruiting shoots. Reduce the young growths to the required number at the same time making them secure against any injury from winds. If a new stock of the Loganberry is desired peg the points or tips of the shoots into pots, plunged into the ground. This is an easy and ready method of propagation, and much to be preferred to division of the stools.

Rhubarb. Hitherto I have not referred to Rhubarb, because it is not a fruit, but as it is used in tarts and for preserves I may be pardoned for mentioning it. Rhubarb plantations have been drawn upon somewhat heavily this season, for obvious reasons, therefore the ground should be lightly forked over between the rows and then given a dressing of either sulphate of ammonia or Peruvian guano. Pulling should now cease, or the plants will be weakened.

PLANTS UNDER GLASS.

By E. Harriss, Gardener to Lady Wantage, Lockinge Park, Berkshire.

Abutilon Savitzii. This is a most useful plant for indoor decorations, and two or three batches may be profitably propagated every year. Insert the cuttings close to the sides of 5½ inch pots and plunge them in the propagating case in a hand-light, or on a Cucumber bed. The best of the old plants may be potted again to make large specimens.

Salvia.—Salvia grandiflora splendens requires abundance of water during the latter stages of growth, supplemented by some form of stimulant two or three times a week. An application of soot-water once a week is also helpful in giving good colour to the foliage. Examine the foliage carefully for red spider, and syringe the plants with an insecticide at the present. Salvia Patcheri is now growing freely, and stakes must be supplied to support the young growths. This beautiful Salvia is often spoilt by allowing too many growths to remain. If the growths are thinned to five or six on each plant very strong spikes of flowers will result. If the pots are not already plunged in ashes this should be done, as S. Patcheri may remain out of doors with advantage until the end of September.

Schizanthus. The first sowing of Schizanthus may be made now in boxes or pans filled with a light sandy compost. Sow the seeds thinly and lightly, and cover with fine soil. They will readily germinate in a cold frame, and it must be borne in mind that the plants resent coddling at any stage of their growth. They should be grown in a light, airy structure, near the roof glass. There are several beautiful types of S. hizanthus, but the large flowered hybrid S. Wisetonensis, and S. retusus, find most favour here for growing in pots.

Clarkia.—A small sowing of Clarkia elegans may be made now and treated as advised for Schizanthus. This plant is most useful for cutting; it must be grown under perfectly cool conditions.

THE APIARY

By Chloris.

Seasonable Hints. As the end of the honey season is in sight a good deal of care is requisite, for only by judicious manipulation can we avoid having left upon our hands a number of partly filled frames and sections. Partly filled sections are only fit for the extractor, as they are useless for sale. All drawn out combs, whether in shallow frame or sections, containing no honey, should be removed at once. It should be carefully made up into parcels and put away in readiness for the new season. The remaining sections should be closed, placing those needing least attention on the outside. The whole must be warmly wrapped up. One warning is essential in giving the above advice. Sometimes when filled sections are removed, and there is much interference, the colony, unless very strong, will, to the disgust of the beekeeper, carry all its stores below. At the same time, it is essential to take some risks if we are to secure the best results. Where the stocks are weak, unite two or more colonies to make strong stocks, and thus make sure of their going through the winter successfully, always supposing they have sufficient food and dry lives.

Driven Bees. In many villages bees are still kept in skeps or hive of some kind, and many are annually destroyed before the honey can be secured. Where driven bees can be obtained for the driving they will be found most valuable for joining to hives that are found to be short of bees. It will even repay a beekeeper to give a trifle for them. Often the driven bees are in such a state of terror that they will not fight, and those to which they are to be added, if fairly well smoked, will be in a like state. Take off all sections and drop the driven bees *en masse* on the top of the frames, having just removed all queens from the added bees, and drive them down with smoke. The inexpert beekeeper may let the bees run in by the entrance, taking care to keep them from clustering under the porch by using a quill or thin stick.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER, *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS**, **41, Wellington Street Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 61.5°.

ACTUAL TEMPERATURE:—

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, August 15, 10 a.m., Bar. 30, temp. 69.5°. Weather Very bright.

Potato Spraying.

The next month will prove an anxious time for those responsible for the food supplies of this country—not because there is a prospect of shortage, but because the larger our harvests the less shall we be dependent on overseas supplies, the less will be the amount of money which we shall have to spend abroad, and the less the tonnage which will have to be employed in the transport of food. Those who are comfortably unaware of the vicissitudes of prospects which may overtake a crop are, perhaps, already reckoning on a bumper Potato yield corresponding to the largely increased area which has been planted this year. Nor can we but hope that this cheery optimism may be excused by results. The recent change from close, wet weather to bright sunshine is of happy occurrence, for it coincided with the very widespread incidence of outbreaks of Potato disease. Now, as all experienced gardeners know, late blight of Potatos—like diseases of parasitic origin generally—is a very hard thing to control if the weather is on the side of the disease, but is relatively easy of control if the weather is on the side of the Potato. Indeed, it is to this fact more than any other that the indifferent attitude to spraying exhibited by so many growers is to be ascribed. They know that if the weather conditions are auspicious blight is not likely to make serious headway; they also know that if the weather is adverse, spraying will have to be done thoroughly and often if it is to serve as a check to the disease. Nevertheless, in view of the large issues at stake, we would urge gardeners to take the lead in their several districts in encouraging that form of Potato insurance which we call spraying. A striking example of the potency of spraying is to be found at the present time in the Royal Horticultural Society's gardens at Wisley, and we commend this example to the officers of the Food Production Department, who are working so energetically in promoting the spraying of Potatos. The Potatos at Wisley have, we are informed, been sprayed twice already. After the first spraying weather conditions were unpropitious, and in spite of the spraying disease made its appearance. The second spraying has arrested the disease so absolutely that at the present moment it is not possible to find any trace of the live fungus. It might be argued that this result is to be ascribed, not to the Burgundy mixture, but to the sunshine. This, however, cannot be maintained, for in the neighbourhood of Wisley Potatos are to be found which have not been sprayed, and in which the disease is progressing in spite of the favourable turn which the weather has taken. It is not often that so clear a demonstration of the fact that spraying has the "casting vote" is to be seen, and we trust that those who are disposed to rely on fine weather saving them the trouble of spraying will lay this example to heart and undertake, in their own and in the national interest, this form of crop insurance.

FLOWERS AT THE WAR SHRINE IN HYDE PARK.—The War Shrine in Hyde Park has been amply furnished with flowers since its dedication early in the present month. Probably not fewer than 200 000 persons have contributed floral tributes, and some business men place flowers on the Shrine each day. A proposal is on foot to erect a permanent shrine in place of the wood and canvas erection which has created such general interest.

PROPOSED TAX ON FLOWERS AND PLANTS.—In the Report of the Select Committee on Luxury Duty we find a proposal to tax purchases of cut flowers amounting to more than 7s. 6d., and plants (including receptacle and its decoration), trees, shrubs and bulbs, when the purchase price of each exceeds 7s. 6d.

THE BLACKBERRY HARVEST.—The Board of Education is advising local education authorities to allow senior scholars three days' holiday during each of the next two or three weeks, if necessary, so that the children may assist in gathering Blackberries for the jam factories. All pickers will be paid, we understand, at the rate of 3d. per lb., and all fruits must be minus the central core as they would be if ripe.

POTASH FROM ALUNITE AND SEAWEED.—The subject of the production of potash is treated in Bulletin No. 415 of the United States Department of Agriculture. It appears that deposits of high-grade alunite have been discovered in Utah, containing a considerable quantity of potash. The present high freight rates militate against any extended scheme, but it is thought that in normal times potash might be profitably extracted from this source. Another probable source of this valuable manure is the abundant plant growth in the water of the Panama Canal, which has hitherto been considered an unmitigated nuisance on account of the hindrance it causes to shipping. Recent analysis has shown that this growth contains from 4 to 6 per cent. of pure potash, and it is proposed to put in hand an extensive scheme for clearing the canal and extracting the potash from the water-weeds.

ALLOTMENTS AT FULBOURNE.—The inhabitants of the little town of Fulbourne, in Cambridgeshire, are doing excellent work in food production. There are only 250 householders, but they hold 71 acres of allotments between them. Moreover, in addition to their allotments, 80 per cent. of the householders have good gardens, which are in the majority of cases extremely well cultivated. The town is to be congratulated on so good a record.

RAFFIA FOR FRUIT-TREE BUDDING.—Under arrangements with the War Office, a limited quantity of raffia has been placed at the disposal of the Food Production Department, to be used exclusively for fruit-tree budding purposes. Those in need of this material should forward at once particulars of their requirements to the Food Production Department, 72, Victoria Street, Westminster. Applicants should state the number of stocks to be budded, and give an undertaking that any material allocated will be used exclusively for fruit tree budding. Applications can be entertained from actual users only, and envelopes should be marked "Raffia, Room 39," in the top left hand corner in order to avoid delay.

RECORDS OF ATTACKS OF FUNGOID AND INSECT PESTS.—Everyone familiar with the cultivation of garden and field crops is aware that the national annual loss of food resulting from attacks of fungoid and insect pests is enormous. How great is the loss and to what extent it may be attributed to the various pests, no one can tell, because correct information on these important points is not forthcoming. We know the difficulty of obtaining reliable information is very great, but, surely, not insurmountable, when once the value of reliable statistics is understood, therefore we are glad to learn that an attempt is being made to obtain records. As a preliminary effort in the collection of statistics which will show (1) the loss in foodstuffs due to pests, (2) the monetary loss involved, (3) the most fruitful direction in which research in control methods might be carried out, and (4) the importance of the matter from the national point of view, a committee representing the Imperial Bureau of Entomology, the Association of Economic Biologists, and the Agricultural Education Association, has prepared an experimental scheme for the recording of the results of attacks of Potato Blight and Fruit Fly. As success depends on hearty co-operation we commend the scheme to our readers, many of whom we hope will apply for record sheets to Mr. F. O. MOSLEY, Laboratory of Plant Pathology, University College, Reading.

SORGHUM AS A SUGAR PLANT.—At the present time, when sugar is scarce, it is interesting to find in the current number of the *Revue Horticole* a reference to the researches of Messrs DANIEL BERTHELOT and RENÉ TRANNOY, who reported in June to the Academy of Science that juice extracted from the stem of the Sorghum (S. vulgare) can be crystallised, and that, when the plant is cut down and the tissues allowed to die, saccharin in appreciable quantities is obtained, in the form of glucose and levulose. It is the opinion of these scientists that the juice could usefully be employed in cooking, when other syrup is not to be obtained. Sorghum can be cultivated in the same climate and under the same conditions as Maize. We may add that in America certain varieties of Sorghum are already cultivated for forage, and for the sake of the saccharin in the stems.

Rose Golden Ophelia.—This Hybrid Tea Rose has been greatly admired wherever it has been exhibited, as it possesses beautiful form and attractive colouring. The light yellow blooms are borne on long, dark stems, and as the foliage is also dark the flowers, with their more deeply tinted buds, have a fine setting. Messrs. B. Cant and Sons were awarded a Gold Medal for this variety at the exhibition of the National Rose Society, held at Regent's Park on July 4, and an Award of Merit by the Royal Horticultural Society on April 9.

Pinus canariensis.—The first part of the *Kew Bulletin* for 1918 contains an illustrated article on the Canary Island Pine, by Mr. J. Hutchinson, who visited La Palma in 1913. One of the objects of this contribution to our knowledge of this valuable tree is to advocate its cultivation for timber in suitable districts of the Empire. Already it has been extensively planted in South Africa, where it succeeds admirably, and it is under trial in Australia and New Zealand. The *Bulletin* illustrations show this Pine growing in the ravines of La Palma. It is the most favourable conditions it attains very large dimensions, with a clean, straight trunk measuring as much as 6 feet in diameter. At the present time there still exists above the village of Vilaflor, to the south of the Peak of Teneriffe, a group of giants at an altitude of 7,400 feet. One of these, according to Dr. Perez, is about 160 feet high and 36 feet in circumference. The same number of the *Kew Bulletin* contains papers on Tagasaste and Gacia as fodder plants, and on Storrie's soil erosion.

A New Dye Material.—The United States Consul-General at Buenos Aires reports that a joint-stock company has been formed in Argentina for the exploitation of a new dye material "algarrobin," obtained from the wood of the Carob tree. Cerutti's Schipani and a factory has been established in the city of Santa Fe. The material is said to be giving good results. One local concern, the Sociedad Italo Americano, is said to be using 3,307 to 4,409 lbs. of algarrobin monthly, chiefly in dyeing khaki for Argentine military uniforms. It is also said that 661,139 lbs. of the product have been shipped to Italy and France, and that additional requests are being received.

London's Railway Station Gardens.—The directors of London Underground Railways encourage the horticultural tendencies of their employés in various ways, and one of these is the granting of prizes to those who provide the best floral displays on the stations they have charge of. The annual inspection of these station gardens took place recently, and first prizes were awarded to the station masters at Northfields and Boston Manor, Hounslow line, and second prizes to Acton Town and Walham Green, besides seven third and fourteen fourth prizes to other stations. The directors have granted £50 towards the prizes to be competed for at the Underground Railway Employés' Horticultural Exhibition at Hammersmith in September, and they have encouraged food production by the extension of allotments on their own land, and the provision of miniature orchards on the wide embankments on the Hounslow and Barrow lines.

Food for Poultry.—To insure an equitable distribution of the limited quantity of poultry food, and also to encourage the better strains of poultry, the Minister of Food, acting with the Board of Agriculture, is putting into operation two systems of rationing, as follows:—Scheme A. Rations of 4 ounces per day per bird will be provided for birds of the best utility breeds up to an aggregate amount of 50,000 tons of feeding stuffs for six months. Scheme B. The owners of other fowls, having hen birds hatched since January 1, 1918, and not receiving rations under Scheme A, will be able to obtain certificates entitling them to purchase up to an amount per head per day (which will be less than 4 ounces a day, to be fixed from time to time according to the quantity of foodstuffs available). The machinery employed under the two schemes will be similar to that set up for a general scheme of livestock rationing to come later—i.e., through the Feeding Stuffs Committees which have been set up throughout the kingdom. Sub-committees of five persons will be attached to each Feeding Stuffs Committee, nominated at meetings of poultry-keepers shortly to be held in every area. To make the committees as fully representative as possible, areas will be divided into five sections, each of which will be entitled to a representative. In order to obtain a special ration of 4 ounces (say half grain and half a mash in dry form—fowls will be classified into first grade and second grade breeding stock. To come within the first category fowls must be:—(*a*) Utility breeding stock for egg production or of high utility quality; (*b*) and of pure-bred stock; (*c*) the standard of health of the flock must be high; (*d*) for a period of at least two years the stock must have been bred to meet the above requirements; (*e*) the owner of the stock must undertake, in consideration of receiving preferential treatment, to supply the public with hatching eggs, day-old chicks, and older stock at a cost no greater than his 1917 charges; (*f*) selective breeding must have been practised in the flock. Stock to be included in the second grade must meet the requirements of (*a*), (*b*), (*c*), and (*d*), and the owner must comply with the condition (*e*). Although no thorough system of selecting the best females has been practised, if the best available males have been regularly used such stock will be worth preserving and should be included in this grade. Second grade birds will only receive rations after the requirements of the first grade have been satisfied. A certain proportion of the allotted foods will be reserved for the preservation of the best utility stocks of ducks, turkeys, and geese. Owners of poultry coming within these conditions must apply in due course on prescribed forms to the secretary of the Feeding Stuffs Committee for their area, and if their applications are accepted they will receive certificates entitling them to a certain amount of feeding stuffs through the retailer whom they have nominated, and with whom they must deposit their certificates.

"Cotton" from Seaweed.—It is stated that the Fukyo Fibre Laboratory has taken out a patent for a process, whereby a substitute for cotton may be manufactured from a seaweed called "Suzame," or "gomo gomo." This weed grows abundantly in Japan, where it has hitherto been known as a good fertilising material. In the process of manufacture the weed is boiled in ashy water, and then in water mixed with Rice bran; afterwards it is bleached.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by their correspondents.)

Old Gardening Books.—I have been much interested in Miss Warner's note under this heading in the *Gardeners' Chronicle* (p. 57), and also, of course, in Mr. Payne's and Mr. Burnyeat's articles, of which it is the outcome. It is particularly interesting to note Miss Warner's reference to her list of gardening books up to 1900. I hope she will extend it to 1900. It has long been a wish of mine to compile a really comprehensive bibliography of gardening books. Of lists there are many, such as that in the Hon. Evelyn Cecil's *History of Gardening in England*, but all these lists fall far short of what I think is wanted. The model I have always had in my mind's eye is Bigmore and Wyman's *Bibliography of Printing*. For many years I have been in the habit of cutting out entries

in second-hand booksellers' catalogues relating to horticulture, and have always hoped at some time to get these into order; the task would not be a light one, and the pressure of urgent literary work, not only in this country but in the United States, has left me no leisure for years past. From time to time during the last twenty or thirty years, but frequently with long intervals, I have written a good deal on the literature of horticulture in *The Gardeners' Chronicle*, and hope to be permitted to do so in future. The subject is almost inexhaustible. I have had the good fortune to discover a good many rarities in the way of "unconsidered" literature, and only within the last few days I had the pleasure of buying the most extensive "Catalogue of Seeds and Roots" I have yet seen. It was printed for John Webb, seedsman, at the Acorn, in Bridge Street, Westminster, and extends to 78 pages quarto. It is undated, but from the typographical get-up I should place it at about 1750. Seedsmen's and nurserymen's catalogues are, of course, part and parcel of gardening literature, and such of them as have been preserved would fall within the scope of the bibliography which I have in my mind. Such a work might be undertaken on the co-operative lines which resulted in such a perfectly wonderful book of reference as the American Library Association's *Portrait Index*, 1906. *W. Roberts, King's Avenue, Clapham Park.*

KEEPING THE AIR OF THE FRUIT ROOM DRY.—However well constructed it may be, the conditions obtaining in the fruit store are often far from satisfactory. At times the atmosphere becomes unduly damp, and this is usually largely due to the "sweating" of the fruit after storage. The admission of air currents is a cure for the trouble, but draughts often bring with them great changes of temperature, which are harmful to the fruits. It has been discovered that the use of chloride of calcium plays an important part in keeping the air of the store dry. This salt has the property of absorbing a large quantity of atmospheric moisture (about double its own weight), and after a while it becomes completely liquid. If a sufficient quantity of the chloride of calcium is introduced the atmosphere in the store will remain in a relatively dry state. The best plan is to place the chloride of calcium in a slanting trough, over the lower edge of which the salt can flow as it liquefies. A vessel of some kind should be placed underneath to receive the liquid. The chloride of calcium should be renewed about every week. The liquid which is captured should be placed in an iron vessel over a fire, and as soon as all the moisture has been evaporated it may be used again and again. Quicklime answers a somewhat similar purpose, though this is not so good as the chloride of calcium. *S. Leonard Bastin, Bournemouth.*

THE APPLE CROP.—Cannot the general failure of the Apple crop be turned to some use? In my own small garden I have some twenty varieties of Apples. The trees are cordons and bush trees, all planted at about the same time, and all of about the same age. Some, albeit few, are bearing a full crop, some have from one third to half a crop, and some have failed. I suggest that if statistics of varieties which have succeeded or failed were compiled, some useful data on the subject of the most trustworthy varieties might be obtained. I know, of course, that there are many factors which have to be taken into consideration before any conclusion of value could be drawn from such data, but I have in mind the possibility that, nevertheless, the information gathered in a careful way, might show that certain varieties—not probably the best—are to be relied on, even in such seasons as this, for producing fruit. Someone once said that the bicycle he wanted was a hardy bicycle, which would stand a large amount of ill-usage. I think this is also true of fruit, and I at all events should prefer to plant serviceable varieties, which can withstand reasonable ill-usage on the part of the weather, rather than, say, the delicious Cox's Orange Pippin, which in my soil scabs with (or without) the least provocation, and is unreliable. *A. N.*

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables in *Gardeners' Chronicle* for August 3, p. 42.)

(*Continued from p.* 62.)

2.—ENGLAND, N.E.

DURHAM.—During the flowering period of Plums, Pears, and Apricots the weather was very unfavourable, and though there was a fine show of blossom, the fruits did not set. Apples also blossomed freely, but the flowers were eaten up by caterpillars. Black Currants, Red Currants, and Gooseberries gave poor crops of fruit, owing to the bad weather which prevailed when they were in flower. *Edward Tindale, Ravensworth Gardens, Gateshead.*

—— Early in the month of May the prospects were good for crops of Apples and Plums, but as the season advanced the weather became very dry and cold, the result being a bad set of fruit. The following varieties of Apples are, however, carrying good crops: Lord Suffield, Warner's King, Lord Grosvenor, Cellini, Gascoyne's Scarlet, and Lane's Prince Albert. Pears against walls bore little bloom; standards bloomed profusely, but did not set much fruit. All fruit trees have suffered severely with insect pests. Amongst bush fruits, Raspberries and Red Currants bore the heaviest crops. The soil is retentive, but we suffered severely from the late drought. *William Smith, Lambton Castle Gardens, Fence Houses.*

—— In the spring there were promises of bountiful crops of all fruits in this county, but a plague of caterpillars and other pests attacked the trees of Apples, Pears, Currants, and Gooseberries in many parts of the county. This considerably reduced the quantity of fruit, but what remains is good. Plums bear abundant crops. *John Smith, County Instructor in Horticulture, Hylton House, North Road, Durham.*

NORTHUMBERLAND.—Apple crops look well and promising. Lane's Prince Albert, Bramley's Seedling, Peasgood's Nonesuch, Lord Grosvenor, Lord Derby, and Domino are the best varieties. Pears, Plums, and Cherries bore very light crops, and in some places none at all. Strawberries yielded a good crop, but owing to the long continuance of dry weather, the plants suffered from want of rain. Black Currants, Red and White Currants, and Gooseberries bore splendid crops, and Raspberries were also good. The soil lies on gravel, and quickly dries up in hot weather. *J. Thomas, Bywell Hall Gardens, Stocksfield-on-Tyne.*

YORKS.—We had a good show of bloom, but owing to a depleted staff spraying was only partially done. In consequence, pests were abundant, and ruined the few fruits that escaped late frosts. The quality of Gooseberries was good, but there was only a small crop. Raspberries were plentiful, in spite of an attack of caterpillars. *J. G. Wilson, Chevet Park Gardens, Wakefield.*

—— The Apple, Pear, and Plum crops are very poor. Apple trees have been infested with the caterpillars of the winter moth, and with aphides. Pear trees, which carried exceptionally heavy crops last year, are this year very sparsely fruited. Plums flowered well, but owing to cold winds and drought at the time of blossoming they failed to set. Gooseberries, Strawberries, Red Currants and Raspberries have been satisfactory. Black Currants were a failure, owing to aphis attacks. On the whole, we are experiencing a very poor fruit season. *C. F. Fulford, North Riding Asylum, York.*

Though there was an abundance of Apple and Plum blossom there are very poor crops of fruit. In the case of the former, it is probably owing to the cold, sunless weather when the blossoms opened. Strawberries promised well, but the want of rain spoiled the crop. There are practically no Pears. Red Currants were very good, but Black Currants were a failure. The soil is heavy loam on a layer of clay, with red sand below. *Jas. E. Hathaway, Baldersby Park Gardens, Thirsk.*

—— Fruit trees generally have suffered severely in this district from drought, which has caused considerable loss of fruits. Caterpillars also did great damage. Very few Pear trees carried blossom this year. This district lies some 700 feet above sea level. The soil is a shallow, medium loam, resting on chalk. *Sidney Legg, Wurter Priory Gardens, York.*

—— The fruit crops are the lightest we have had for some years past. Pears, Apricots and Peaches flowered badly, and are yielding thin crops. Apples have suffered from the caterpillar plague, and Strawberries were badly affected by drought. Other crops are fairly satisfactory. *F. C. Puddle, Scampston Hall Gardens, Rillington.*

—— This is one of the worst fruit seasons I have experienced. Apples will be a very poor crop; in fact, in some orchards there is not an Apple to be seen. Pears are a complete failure. We have a heavy crop of Plums, especially Victorias, although they are very scarce in the district. The same remarks apply to Gooseberries, Raspberries and Red Currants. Black Currants were a failure. Strawberries looked promising, but, owing to the dry season, were soon over. *J. C. Sutton, Castle Howard Gardens, Welburn.*

3.—ENGLAND, E.

CAMBRIDGE.—Early in the season we had a good display of blossom on outdoor fruit trees, but continuous cold nights, followed by the long drought, destroyed all prospect of good Apple, Pear, or Plum crops. The soil here is light, with a chalky subsoil, and soon dries up. *B. Goodacre, Moulton Paddock Gardens, Newmarket.*

After a splendid show of blossom, the crops of Apples, Pears, and Plums were injured by a long spell of cold, east winds. The subsequent dry weather caused the few remaining Apples to drop off. Just as Strawberries were setting a very heavy rain and hail storm (3.72 inches in 2 hours) destroyed all prospects of a good crop, only late varieties escaping. *Arthur Sweet, Palace Gardens, Ely.*

(*To be continued.*)

ORMSKIRK POTATO TRIALS.

As our account of the Potato Trials conducted at Ormskirk (see p. 60) has created considerable interest and a desire for detailed information concerning the immunity, or otherwise, of varieties from Wart Disease, we have now the pleasure of publishing the following particulars:—

Over 300 lots were tested. Amongst first rather, up to the present the greatest difficulty has been experienced in obtaining suitable immune Potatos similar in shape and colour to such varieties as May Queen, Midlothian Early and Sharpe's Express, all of which are highly susceptible to "Black Scab" on infected land. There are signs, however, that these difficulties are about to be overcome.

FIRST EARLY VARIETIES.

Dargill Early.—A very promising white kidney which has proved itself immune up to the present; known in previous years as Gardiner's No. 1.

Resistant Snowdrop (W.K.).—The white-fleshed form of this old variety still refuses to be contaminated, while the yellow fleshed form is most susceptible.

In obtaining clean stocks the great safeguard is to cut every set and examine until a pure strain is obtained. Both the foregoing are fair croppers.

Edzell Blue, an old, Forfarshire, round variety, is perfectly immune, and although coloured is a good cropper and of excellent quality.

Sutton's A 1 (W.R.) is another early variety which has proved to be immune, but its crop-

ping powers are only moderate, and it has, in the opinion of many, the defect of being round and deep-eyed.

America (W.R.).—A promising Potato which may replace Epicure on infected soil.

Arran Rose.—A very distinct, coloured, round Potato; cropping and quality good.

SECOND EARLY VARIETIES.

King George (W.O.).—Undoubtedly the coming second early variety for infected soil, where a Potato of the British Queen type is desired. At present the quality is not first-rate, but this will possibly improve with time; good cropper.

Great Scot (W.R.).—A Potato of great merit; a heavy cropper, of good quality, and robust constitution.

The Ally (W.O.).—This was awarded a Gold Medal in the 1917 trials. It is one of the great Potatos of the future, possessing foliage of a distinctive grey colour; the quality is improving. It produced a crop of 16 tons per acre in experiments carried out by the Lancashire County Council.

Arran Comrade (W.O.).—Known as Seedling No. 38 in 1917, this is a Potato of considerable promise.

EARLY MAINCROP VARIETIES

In this section the varieties of the Abundance type are in the majority of cases most susceptible, but promising immune varieties such as Culdees Castle (W.O.) and Burnhouse Beauty (W.O.) may be mentioned as exceptions.

LATE MAINCROP VARIETIES.

The Lochar (W.R.).—A good keeper and a fair cropper; it must be considered as a useful variety until replaced by a better. The foliage is not so robust as might be desired.

Templar (W.R.).—A moderate cropper.

Majestic (W.R.).—A variety of great promise, of good quality, and a satisfactory cropper. This variety has several points to recommend it, such as shallow eyes and fine appearance.

Kerr's Pink (C.R.).—This variety, which was awarded a Gold Medal in 1916, still retains its popularity as a fine cropper, and is of good quality.

Rhodesia Dhu (W.R.).—A variety apparently possessing a robust constitution, with massive stems and broad green leaves, which are so very characteristic that the Potato stands out conspicuously in the trials this season.

Amongst a large number of seedlings undergoing the test for immunity the most promising are:—Seedling 139, A.I. (W.R.); late: Seedling 472, C/2 (W.R.); late: Seedling 142, 2/6, (W.R.); late: Seedling 172, 10/6 (W.R.); late: Bloomfield, W.O.; second early: Laing's Prolific, W.O.; second early.

The whole area on which the varieties are being tested has received the following dressing of manure per acre:—12 tons farmyard manure, 4 cwts. superphosphate, 1 cwt. sulphate of potash, and 1 cwt. sulphate of ammonia.

(W.R. = White Kidney; W.R. = White Round; W.O. = White Oval; C.R. = Coloured Round. Ens.

The very wide circle of people interested in Potato culture will appreciate the prominence given on p. 60 to "Ormskirk Potato Trials, 1918," and also the credit given to Mr. John Snell and the Ormskirk Potato Society for the way they have stuck to their work for the last six or seven years. The pioneer work done by Mr. G. T. Malthouse at the Harper Adams College should not be forgotten. I believe the prospects for the future of such an important work are very bright. A sub-station of the Institute of Agricultural Botany at Ormskirk for the study of Wart Disease in Potatos, as foreshadowed by Mr. Lawrence Weaver, will set the work in its proper perspective.

Your remark on p. 60 that "the conditions under which the trials are carried out do not enable the full cropping capabilities of the varieties to be ascertained" struck me, and many who were present at Ormskirk on the 30th and 31st ult. must have felt how true your statement is, and yet I have seen splendid crops in the workhouse grounds there. I have seen Golden Wonder yielding 10 tons to the acre and Kerr's Pink 12 tons or more. I think the drought must have told very severely, especially against all the early sorts this season, and I think it was unfortunate that the plants at the ends of most of the rows, which were the ones lifted, showed up so poorly. The land must be better cultivated, and Mr. Weaver must see that Mr. Snell has as much "muck" as he wants, and artificial manure to give them at least a 10 cwt. dressing.

The other day I had the pleasure of showing Messrs. Dobbie and Co.'s trials at Edinburgh to a party including such authorities as Mr. Chittenden, of the R.H.S., Mr. Taylor, Mr. Gough, Mr. M'Ilvee, and Mr. Wolf, of the Board of Agriculture. Many of the plants lifted gave 4 to 5 lbs. per root, and one of the party asked our grower what he manured with. The answer came in a dry, matter-of-fact way: "The usual 20 tons of dung and 10 cwts. of artificials." In a season like the present one the advisability of planting whole sets of fair size is most evident.

We shall all await with interest the final report of the Trials, when the whole of the rows have been lifted. It was gratifying to see previous years' results confirmed, so far as that was possible from the small quantities raised. Edzell Blue, Majestic, Kerr's Pink, Great Scot, King George, The Ally, and all the Abundance type showed no trace whatever of Wart Disease. Interest centred in the new sorts not yet on the market, such as Arran Comrade and Arran Comrade (second early). The last-named, raised by Mr. McKelvie, of Arran Chieftain, carried off the honours of the day, judging by the high opinion formed of it by every hand. H. Cuthbertson. *Dalmeny, Midlothian.*

SOCIETIES.

ROYAL HORTICULTURAL.

AUGUST 13.—Very few visitors and the hot day caused the Council to make the exhibition to-day the date of the London Show Drill Hall a quiet one, and things by no means the smallest to be seen.

The Floral Committee recommended six medal awards, but made no awards to novelties. The Fruit and Vegetable Committee made no awards, and the Orchid Committee granted only two medals and two Awards of Merit.

Floral Committee.

Present: Messrs. Henry B. May (in the chair), W. P. Thomson, Chas. E. Pearson, Chas. Dixon, Chas. E. Shea, H. J. Jones, J. W. Moorman, J. Jennings, J. F. M'Leod, Arthur Turner, W. Howe, J. Hudson, C. R. Fielder, G. Routhe, John Green, R. C. Notcutt, Sydney Morris, W. J. Bean, J. T. Bennett-Poe, Herbert Cowley, R. W. Wallace, W. G. Baker, E. H. Jenkins, E. A. Bowles, and Jas. Hudson.

INTERESTING PLANTS.

The principal feature of the meeting was an extensive display of finely grown Gladioli from Messrs. Kelway and Son. The range of colour seen in a series of about eight varieties and an aggregate of about 250 spikes was very wide. The most attractive varieties were Marshal Foch, orange-scarlet; Lt. Kelway, a soft orange-scarlet, form evidently derived from *S. primulinus*; Golden Fire, golden apricot; Golden Ray, soft apricot-yellow; and White Lady, white with pale yellow blotch.

Mr. G. Reuthe showed several very interesting plants, notably Gaultheria rupestris, with white berries; G. Veitchii, with blue berries; and Lonicera tibetica, with three leaves at each node, and a pair of small, rose-pink flowers arising from the axils of each leaf along the flowering portion of the slender shoots. Messrs. Robert Veitch and Sons exhibited fine blooms of the splendid Magnolia grandiflora Exmouth variety; flowering growths of Acacia falcata from out-of-doors in Exeter—an interesting, yellow, autumn-flowering species; heavy-trusted sprays of Viburnum rhytidophyllum, and flowering bunches of Eucryphia pinnatifida and Exothrina Cristi-galli. A very densely-flowered and brightly-coloured form of Statice incana, shown by Mr. F. G. Woop, Marsden Gardens, Ashtead, merited a Cultural Commendation.

GROUPS.

The following Medals were awarded:—*Silver Flora Medal* to Messrs. Kelway and Son for Gladioli; and to Messrs. H. B. May and Sons for Ferns. *Silver Banksian* to the Rev. J. H. Pemberton for Roses, and to Mr. G. Reuthe for Alpine plants and shrubs. *Bronze Flora* to Messrs. J. Cheal and Sons for Phloxes. *Bronze Banksian* to Mr. G. W. Miller for hardy flowers.

Orchid Committee.

Present: Sir Harry J. Veitch (in the chair), Messrs. Jas. O'Brien (hon. secretary), William Bolton, R. A. Rolfe, Frederick J. Hanbury, C. J. Lucas, Walter Cobb, Arthur Dye, W. H. Hatcher, J. Charlesworth, A. McBean, R. G. Thwaites, Stuart Low, Fred. Sander, and Chas. H. Curtis.

AWARD OF MERIT.

Cattleya Hesta alba (*C. Suzanne Hye de Crom* × *C. Warscewiczii Exon. M. Beyrodt*), from Messrs. Charlesworth and Co., Haywards Heath.—A pretty and distinct pure white flower, and the first albino to appear out of the batch, as the others, having the purple front to the lip as in the Warscewiczii parent, but varied in tint in the various forms. The variety now shown had pure white flowers with light chrome yellow disc to the lip.

Laelio-Cattleya Appam (*L.-C. Scylla* × *C. Dowiana aurea*), from Messrs. Charlesworth and Co.—A very brightly coloured hybrid, in colour approaching nearest to *L.-C. Cappei*, one of the parents of *L.-C. Scylla*, and in form to *C. Dowiana*, which enters a second time into its composition. The plant bore a spike of three well-formed flowers with deep golden-yellow sepals and petals and ruby-purple lip, having closely arranged orange-coloured lines from the base to the centre.

GROUPS.

Messrs. Charlesworth and Co. were awarded a Silver Flora Medal for a group in which were many forms of their Laelio-Cattleya Appam, the sepals and petals of the different forms varying from primrose-yellow to light orange, and the labellums from rose-purple to claret-red. One form, in the rich copper-red of its segments, gave distinct evidence of Laelia cinnabarina, one of its original ancestors.

Messrs. Stuart Low and Co., Jarvisbrook, Sussex, were awarded a Silver Flora Medal for an excellent group in which many specimens of their floriferous type of Cattleya Warscewiczii were the chief feature. Most of the spikes bore six to seven flowers each, and one had a spike of eight large, well-developed blooms. In the centre of the group was a fine specimen of Dendrobium elavatum with twenty spikes of rich yellow and maroon flowers.

Messrs. Sanders, St. Albans, showed Cattleya Hardyana Marshal Foch, a very handsome variety with pure white sepals and petals and a deep ruby-purple lip having gold lines from the base to the divided yellow disc.

Fruit and Vegetable Committee.

Present: Messrs. J. Cheal (in the chair), W. Poupart, J. W. Bates, W. H. Divers, George Woodward, G. P. Berry, J. C. Allgrove, A. Bullock, Owen Thomas, F. A. Bunyard, and the Rev. W. Wilks.

Sir A. Cory Wright (*per* Mr. J. Hamlin) showed two fruits of Melon King George; these had grown so closely together that eventually they became joined, though the attachment was very slight, not skin deep. Two early Apples, Duchess of Bedford and Premier, were brought up from the Wisley Gardens, but neither variety received official commendation.

TRADE NOTES.

ALLOTMENT HOLDERS AND THE SEED TRADE.

On behalf of the United Council of Seed Trade Associations, Mr. H. Morgan Veitch has sent us a copy of the following interesting correspondence which has recently passed between Mr. Weaver, of the Food Production Department, and himself:—

"Norfolk House, Norfolk Street, W.C. 2.
"August 8, 1918

"Lawrence Weaver, Esq.,
"72, Victoria Street, S.W. 1.

"Dear Sir,—You have possibly seen in the horticultural press a report of a discussion which you had with a deputation of the Lower Thames Valley Association of Allotment Societies. This report purports to give a summary of your remarks as they were reported in *The Surrey Comet*, and alleges that you stated you were prepared to allow Associations every facility for purchasing seed in bulk," and urged them to write to the Agricultural Wholesale Society, etc.

"I cannot help thinking that there must be a serious error in the report, as I understand this meeting was held at the time when you were going into the matter with a sub-committee of the Unit d Council of Seed Trade Associations, whose suggestions you considered worthy of adoption.

"As the matter is causing considerable unrest in the seed trade, and particularly in the retail branch, I should be much obliged if you would let me hear from you, at your earliest convenience, what is the true construction which should be placed on the report of your statement to the deputation from the allotment societies mentioned above. I think it would be well for me to publish your reply.—I am dear Sir, yours faithfully, "H. MORGAN VEITCH,
"Solicitor to the Council."

"Food Production Department,
72, Victoria Street, S.W. 1
"August, 1918.

"Dear Sir,—I am in receipt of your letter of yesterday. There seems to be a good deal of misunderstanding as to what took place at my interview with the representatives of Allotment Holders' Associations. I have not seen the report in *The Surrey Comet* to which you refer, but the extract you give suggests that it does not accurately represent what took place. The facts are these:—

"1. A deputation representing several Associations called on me and said that certain wholesale seed firms were unwilling to supply them with seeds at wholesale prices. They desired that the Board should compel them to do so.

"2. I replied that the Board had no power or desire to interfere in such matters, but that I would represent their wishes to the wholesale merchants who were members of the Food Production Department's Seed Advisory Committee.

"3. I said further that Associations of Allotment Holders affiliated with the Agricultural Organisation Society could purchase their requirements through the Agricultural Wholesale Society. In this I was merely stating a well-known fact.

"4. In the course I pointed out to a Sub-committee of the United Council of Seed Trade Associations which called upon me, that the Allotment Holders' Associations desired to deal with wholesale houses. I invited them to state the terms on which they would accept orders, and they gave me particulars of the terms which they intended to submit to their Council, for recommendation to members of the Seed Trade Associations as an economical method for overcoming the apparent deadlock.

"5. These terms I communicated to the Allotment Associations which had previously called upon me.

"In this matter the Food Production Department's function was to act as an intermediary between the United Council of Seed Trade Associations and the Allotment Holders' Associations.—Yours faithfully,

"LAWRENCE WEAVER.

"H. Morgan Veitch, Esq."

CROPS AND STOCK ON THE HOME FARM.

POULTRY FOR STOCK.

It is time to select birds of both sexes for next season's egg and chicken production. The pullets and cockerels should be separated, as they grow more sturdily when kept apart. Birds of either sex with crooked breast-bones, badly coloured legs for the variety, wry tails, defective combs, and wrong feather markings, should be separated from the selected birds. Pullets hatched at the end of March or early in April should lay in the autumn, but even with pullets of that age much depends upon the way in which they are managed. Choice of breed is important, but it is purely a matter of local circumstances and personal choice. A more important point is "strain," and this is a point which many poultry-keepers do not trouble about. Pure-bred fowls of any breed vary in their laying capacity, but if the best laying hens are selected a superior strain is obtained. A hen producing 200 eggs per year is a good layer, but a hen of the same breed may not lay more than half that number under the same conditions. Pullets bred from the superior strain are likely to be prolific layers. Every poultry-keeper can collect his own flock of poultry on these lines by the aid of trap-nests and selected hens, as a record can be kept of the number of eggs each hen lays during a year.

Even with a desirable selection of pullets the result may be nullified by neglect of cleanliness and by poor housing accommodation in the autumn and winter.

BASIC SLAG FOR WHEAT.

This artificial manure is fast becoming popular for cereals as well as for grass, and with the increase in motor power, fewer horses will be employed, and consequently less animal manure will be used. Under such conditions, artificials will be of necessity more employed. As the highest grade basic slag—42 per cent. soluble—is now unobtainable, the 30 per cent. grade will be in greater demand, and as only a limited quantity is available of any grade, supplies should be procured as soon as possible.

Stiff to medium loams, or gravel overlying a clay subsoil, and deficient in lime, would be improved by a dressing of basic slag, especially where Wheat is to be the next crop. Assuming that the field has been cleaned of weeds and cannot be given a dressing of farmyard manure, basic slag, applied evenly over the field, at the rate of 6 cwt. per acre, at the time of sowing the Wheat, would greatly assist the production of a full Wheat crop.

TRIFOLIUM INCARNATUM.

For horses and sheep this is a valuable food in May, June, and the early part of July. Early sowing is important, to enable the plant to make good progress before winter rains set in. The common method of culture is to select a clean piece of Wheat or Oat stubble, cultivate it thoroughly to remove as much of the stubble as possible, sow the seed at the rate of 20 lbs. per acre, well harrow it in, and roll the land firmly. Where the stubble is clean this method answers very well, especially if the cereal crop was a good one and the land is in good condition, but if not it is better to plough the land some 5 inches deep and thoroughly bury all weeds. Harrow the plot over once and dress with 6 cwt. of superphosphate per acre, then again harrow it twice to bury the superphosphate.

Trifolium needs a firm rooting medium, as it is liable to have its roots disturbed by frost when the soil is loose. The ground cannot be made too firm, therefore err on the side of firmness by harrowing and rolling well before sowing. If the soil is in good condition, 16 lbs. of seed will produce a good crop, but if the condition be less satisfactory, say, 20 lbs., as the plant will not tiller or bush under poor conditions. *E. Molyneux.*

Obituary.

THE LATE MATTHEW TODD, J.P.—By the death, in his 79th year, of Mr. Matthew Todd, J.P., at his residence Stoneybank, Musselburgh, on the 7th inst., one of the best-known members of the floral trade north of the Tweed has passed away. Mr. Todd was a Kilmarnock man, but by far the larger part of his lifetime was spent in Edinburgh, to which he migrated many years ago. For a number of years he represented the Lawson Seed and Nursery Co., Ltd., then under the management of the late Mr. Syme, and for over forty years he carried on the floral business of Messrs. Todd and Co. He was one of the original members of the Scottish Horticultural Association, on the Council of which he served altogether for about thirty years, and of which he was president in 1897 and 1898. He was also president of the Edinburgh and Leith Floral Trade Association for a term. A man of many parts and wide reading, Mr. Todd was also an effective speaker, and his services were frequently in request as a lecturer on floral art. He had been in bad health for some time, but the end came rather unexpectedly. He is survived by Mrs. Todd and a family of sons and daughters.

ANSWERS TO CORRESPONDENTS.

BEDEGUAR GALL ON WILD ROSE: *G. E.* The galls found so frequently at this season on the wild Dog-Rose are caused by a small insect named Rhodites rosae. The popular name of the moss-like production is the Bedeguar Gall: the specimen sent is a particularly fine one.

DISEASED ONIONS: *H. C. P.* The disease from which your Onions are suffering is Onion Sclerote (Sclerotinia bulborum), which is identical with the disease which sometimes does so much harm to Hyacinth bulbs. The first signs of attack are yellowish markings on the foliage in spring or early summer. The fungus works downwards, and subsequently produces the dark, blackish sclerotia which often disfigure the surface of the bulbs. Spraying with a potassium sulphide solution as soon as evidence of attack is seen will check the progress of the disease, but early spraying is necessary as a preventive measure. Do not grow Onions for two or three years to come on the site of the present bed.

NAMES OF PLANTS: *W. S.* Stachys lanata.—*R. S.* 1, Send when in flower; 2, Viburnum Opulus; 3, Spiræa Douglasii; 4, Rondeletia speciosa; 5, Asplenium Nidus; 6, Jasminum nudiflorum; 7, Weigela rosea.—*J. W. M.* 1, Melilotus officinalis; 2, probably Hieracium cerinthoides.

RIPE TOMATOS IN APRIL: *J. S.* To obtain ripe Tomatos in April it is necessary to raise plants from seeds sown during the third week in September. Winter the plants within a few inches of the roof-glass of a house in which a temperature ranging from 55° to 60°, according to the weather, can be maintained, the aim being to keep them from becoming drawn during the dull season. Pot the seedlings into 3-inch pots as soon as they are large enough, and from there into 5-inch pots before they become pot-bound and stunted. By this means good, strong plants should be ready for their final potting in January. Fruits of Frogmore Selected Tomato, produced by plants raised and treated in the manner described, secured a First-class Certificate for the variety on April 24, 1894, but many ripe fruits were gathered before that date. Very early Tomatos may be grown on plants raised from cuttings rooted in October. In order to make sure of an early crop it is necessary to pollinate the flowers.

RUST ON BEGONIAS: *A. T.* The rusty appearance of the Begonia leaves is due to the presence of a minute mite. Dip the affected plants in a nicotine mixture or dust the foliage while moist with tobacco powder. Some Ferns, Gloxinias, and Achimenes are liable to attacks, therefore if any of these plants are near the Begonias they should be similarly treated to prevent the spread of the pest.

DOUBLE CROPPING IN THE LEA VALLEY.

THE third annual Report from the Experiment Station of the Lea Valley Nursery and Market Garden Industries Development Society contains a brief record of the experiment of double cropping with Potatos followed by Tomatos. The yield of Potatos under glass was from 5 to 7¾ tons per acre, and the yield of the successional Tomatos was 21 to 24 tons. In as much as the yield of Tomatos grown in adjoining houses, and not preceded by Potatos, was 35 to 40 tons, there was a loss of 12 tons of Tomatos to set off against the gain of 6 tons of Potatos. Even so, the food value of the Potato plus the Tomato crop was greater than that of the larger Tomato crop. The report does not give the date at which the Potatos—Eclipse, Sharpe's Express, Duke of York, and British Queen—were planted, nor that at which they were lifted.

The chief objection to using Tomato houses for early crops lies, of course, in the fact that to grow Tomatos in the remarkably successful way in which they are grown in the Lea Valley means labour in the houses practically all the year round. The crop remains in the ground a long time, and as soon as it is finished the houses have to be got ready for next year's crop. When the soil has to be sterilised, the length of time available for an additional crop is very short indeed. Moreover, delay in setting out the Tomatos may result, if the season turns out to be an early one, in no inconsiderable loss of the earlier and more valuable fruits.

It is not, therefore, surprising that experienced growers should be loth to add to their heavy work by additional cropping. That they did so in 1917 by growing Potatos, and in 1918 by growing also Lettuces and Radishes, is an indication of their open mindedness and patriotism. We hope they will continue the experiment, and we feel sure that if they do so by growing the catch crops already mentioned they are likely to find a good market for all they can produce. The shortage of fruit and the probability of a deficiency of jam make it desirable that the largest possible quantity of fresh vegetable food should be available early in the year. Many people look upon salads as mere luxuries. They are wrong. Vegetables, such as salads, eaten raw, contribute more to health than almost any other form of food. For man does not live by calories alone. He requires, if he is to retain his health, the natural preventive medicines which plants can provide. These natural medicines, known to the learned as anti scorbutic vitamines, are the agents which protect the human body from scurvy. If the food which is eaten lacks these substances, no matter how rich it may be in the body building and heat producing foods, malnutrition follows. Therefore every means should be taken, particularly at the present time, to provide, as a constituent of the nation's diet, a liberal allowance of fresh vegetables, and particularly of such salads as Lettuce. Cooking destroys some of the substances which protect the body against such diseases as scurvy, and the surest way to obtain a good dose of those medicines which Nature prepares for us is to use plenty of salads which can be eaten raw.

Persons with glasshouses, provided they can obtain fuel, will be doing a useful service to the community by growing during the winter large quantities of Lettuces of suitable kinds, such, for example, as Little Gott.

Whilst on this subject it is worth while reminding our readers that in dried Beans and Peas the anti scorbutic vitamines disappear, but that they reappear when the seeds are soaked for 18 hours. Since the soaking also makes the seeds more palatable, those who are setting aside a store of Dutch Brown or other Haricot Beans, or Peas, should not forget to insist that before the seeds are cooked they should be soaked in water for 18 hours, care being taken to prevent mould, &c., from developing by changing the water once or twice.

SPHAERALCEA.

The genus Sphaeralcea, consisting of about 25 species, belongs to the natural order Malvaceæ. Some confusion exists respecting the nomenclature of the various members of the genus, some being included by various authorities in the closely allied genera Malva, Malvastrum, and Nuttallia, among others. The majority are natives of North and South America, while some species are also found in South Africa. Of these probably only seven are in cultivation: S. acerifolia, S. ambigua, S. australis, S. bonariensis, S. miniata, S. Munroana, and S. pedata. They are nearly all of subshrubby habit, dwarf and erect, an exception being S. pedata, which is procumbent. Some species are quite hardy when planted in hot, dry positions, others require to be lifted and potted, or propagated by means of cuttings in autumn and kept in a frame during the winter.

S. acerifolia is a half hardy, shrubby plant growing about 4 feet high, with five lobed, cordate leaves, and terminal, compound spikes of rosy-purple flowers in July. It is best adapted to greenhouse culture, although it will survive the winter in sheltered situations. A native of North-Western America, it has been grown in gardens for over half a century.

S. ambigua (fig. 26).—This species was shown at the meeting of the Royal Horticultural Society on June 20, 1916, under the name of S. cæspitosa, by Sydney Morris, Esq., Earlham Hall, Norwich, and received an Award of Merit. S. cæspitosa is not a published name, and I have not learnt who affixed it to this plant, but comparison with herbarium specimens shows that it is undoubtedly S. ambigua, which is found in Southern California, Nevada, and Arizona. This plant was found by Sir Hugh Beevor growing in gravelly ground in Arizona; he collected seeds and gave some to Mr. Morris, who succeeded in raising plants, and states that the plant is quite hardy at Norwich. It is grown in a hot, dry place, and freely reproduces itself by means of self-sown seeds. It is a dwarf, shrubby plant growing from 1 foot to 3 feet high, with stems and leaves covered with a white, woolly tomentum, giving it a silvery appearance. The leaves are about 1 inch in diameter, some deeply divided into three segments, others deeply crenated only. The flowers, which have been described as coppery-red and reddish-orange, might more correctly be described as raw salmon in colour. They are borne in the axils of the leaves along nearly the whole length of the stems in great abundance during the summer months. In Gray's *Flora of North America* the colour of the flower is given as rose, but this is accounted for by the fact that the flowers of S. ambigua turn to a purplish rose shade when dried. This I have proved from experience.

S. australis. A compactly growing species 1 foot to 2 feet high, much branched, the stem and leaves being covered with a woolly tomentum, especially on the younger parts. The leaves are about 1½ inch long, ovate in outline, and deeply pinnately divided almost to the midrib into narrow lobes. The deep salmon-coloured flowers, 1 inch across, are produced one or two together in the axils of the leaves of terminal branches during the summer months. Plants of this species were received at Kew in 1913 from Capt. Savile Reid who raised them from seeds received from the Argentine Republic, of which country it is a native. It makes an attractive subject for a ledge in the rock garden, being quite hardy in a hot, dry situation.

S. bonariensis. Introduced from the same source as the above and at the same time, this plant bears rosy pink flowers in the axils of the leaves of terminal branches. Over 1 foot high, the much branched stems and three lobed ovate leaves are covered with a white, woolly tomentum. It is of more flexuous habit than *S. australis*, and the flowers are rather larger, but not so freely produced. It has proved hardy in a hot, dry place, and remains in flower for a long period.

S. miniata. This is an old garden plant which has been in cultivation over a century, having been introduced in the year 1793. It is, however, uncommon, and seldom seen in gardens. From 2 feet to 4 feet high, it makes a good, bushy plant, with stem and leaves covered with a woolly tomentum not so white as in species previously mentioned. The leaves are about 2 inches long, three lobed, with the middle lobe much longer than the others. The vermilion-red flowers, over 1 inch across, are axillary, in bunches, on long peduncles. It is only half hardy, and makes a good greenhouse plant. Its native country is the Argentine.

S. Munroana.—Two plants are met with under this name in gardens, the true plant, with erect stems 2 feet to 3 feet high, and a prostrate plant, which is really *S. pedata*. The stems and leaves are covered with short, woolly hairs, but are quite green. The leaves are nearly 2

inches long, three-lobed or rarely one being deeper than the others. The dark red sometimes orchid scarlet, flowers are produced all through the summer, one or two together, in the axils of the leaves along the greater part of the stem. Variously known as Malvastrum Munroanum and Malva Munroana, this plant has been in cultivation since the year 1826, and is quite hardy in hot, dry places in stony soil, where it spreads by means of underground stems. A native of Western North America.

S. peltata.—Also known as Malva Creana, this is a procumbent plant, with long, interlaced stems covered with stellate hairs, as also are the leaves. The latter are green, trilobed, with the lobes again divided or lobed. The purplish, rose-coloured flowers, 1 inch across, are produced in the axils of the leaves all along the stems during the whole of the summer months. It is not hardy, but cuttings root readily in the autumn, and these must be kept in a frame during the winter. When planted out in late spring the plants make rapid growth, and soon cover a large space. It is a good plant for a warm position in the rock garden, where it can hang over a ledge. *W. J.*

TREES AND SHRUBS.

MAACKIA AMURENSIS.

Though this cannot claim the handsome appearance of some of its showy members of the Pea family as the Laburnums and Robinias, but it flowers in July and August, long after they are past. A tree, about 10 feet high, in the grounds of Holland House, Kensington, is now quite conspicuous and effective in the distance, with its erect racemes of creamy-white flowers, the racemes being 5 inches to 5 inches long, and mostly nearly erect, thus surmounting the horizontal and drooping, pinnate leaves. This small tree blooms more or less every year. It is generally known as Cladrastis amurensis, but for botanical reasons, Mr. Bean, in his book of *Trees and Shrubs Hardy in the British Isles*, adopts Ruprecht's name of Maackia amurensis. Occasionally the base of the raceme is branched, but it is so dense as to resemble a spike in the distance. Though introduced in 1864, M. amurensis is far from being common in collections of trees and shrubs, but its late flowering recommends it. *J. F.*

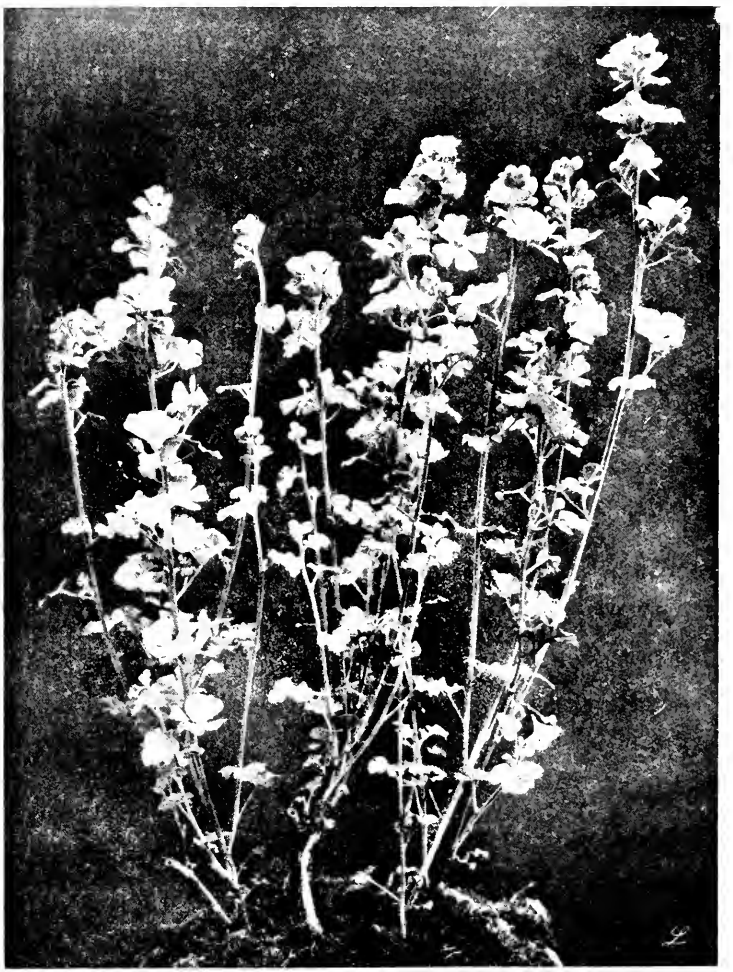

Fig. 26.—Sphæralcea ambigua: flowers raw salmon colour. (See p. 75.)

GAULTHERIA TRICHOPHYLLA.

Gaultheria trichophylla, to which an Award of Merit was granted by the Royal Horticultural Society on July 16 (see p. 28), is the dwarfest and possibly the choicest of the Partridge Berries. It is also, perhaps, the most difficult to cultivate, although in some places it appears to call for no special consideration such as it requires in the majority of gardens. It succeeds in a low, peaty position where it is below the level of the surrounding ground, but I have seen it growing satisfactorily planted with other peat-loving subjects in a slight depression at the base of a rock garden, where it receives the full advantage of all the rainfall and may be easily watered if this is necessary during a dry period.

G. trichophylla is a quite tiny Himalayan plant, with small, pinkish, or nearly white flowers, and hairy leaves, almost fur-like. This hairiness I believe accounts for some of the losses experienced during winter in our climate. The charm of G. trichophylla, however, does not consist so much in its flowers or foliage as in the berries. These are of a most brilliant blue, and larger than one would expect from such a plant. *S. Arnott.*

MAGNOLIA GRANDIFLORA AS A STANDARD.

Referring to the note on p. 63, a few years ago I saw in the Exeter nursery of Messrs. Robert Veitch and Son a large block of young standards of the Exmouth variety of Magnolia grandiflora in full bloom. These young specimens were from 4 feet to 5 feet high, and most of them bore several very large, fragrant blooms, making a memorable display. I have no doubt the blooms of this variety shown at the R.H.S. meeting on August 16 in the very interesting little collection of flowers from the open ground, were from some of these same plants. The type was also in flower, and I know that flowering standards of it are not uncommon around Exeter. Years ago, at Dropmore, Bucks, a standard Magnolia grandiflora produced occasional flowers, and probably would have bloomed more freely had it been in a sunnier position, for it was quite healthy. The "wind-dashed blooms" of February which *Amateur Gardener* saw at Falmouth were doubtless the rear-guard of the previous year's display, for at Pencarrow, in a much colder part of Cornwall, I was usually able to have a bloom to place indoors on Christmas Day, and still leave unopened buds on the wall-plant. Although the fruiting of Magnolia grandiflora is moderately frequent in the West of England, I have never seen ripe and fertile seeds produced in this country. *T. C. Bartlett.*

FRUIT TREE PESTS AND DISEASES.

My fruit trees are now practically free from insect pests, with the exception of American blight. The early attacks of caterpillars are over, and the rains seem to have washed away the aphides. Mention should be made of wasps, however, which are present in exceptionally large numbers this year, attacking Plums as soon as they ripen. Two large nests of tree wasps have been found in the orchards, and many of the ground nests of the common variety have been destroyed with cyanide of potassium.

Some of the fungous diseases are more prevalent than usual. Of these brown rot is the most serious. Very many Plums rot as they ripen, and Apples are attacked at quite an early stage. Prof. Salmon reports that this disease is general throughout Kent, where whole branches of Plum trees have been killed by it. Another disease common this year in my orchards is that known as "eye-rot." This is

a rot which starts at the eye of the Apple and spreads in a circular patch, spoiling the fruit for any purpose. It was first noticed here in 1916, and I do not think it is common. Apple scab made an early appearance on the foliage, and is now disfiguring the fruit of such varieties as are liable to it, notably Worcester Pearmain, Lord Grosvenor, and Allington Pippin, in spite of spraying once with lime-sulphur after the petals fell. Beauty of Bath, which used to be a very clean Apple here, is badly scabbed for the second year in succession, the disease causing cracks and distortion as well as the more characteristic spots.

American Blight.

Correspondents who have kindly responded to my request for experiences in the treatment of American Blight have supplied some very useful information. It is evident that there are several local remedies that can be brushed into the infested spots with good effect. Of those mentioned by correspondents creosote appeals most to me, on account of its cheapness and its power of penetration. I should have been rather afraid to use it, having been given to understand that it is so deadly to vegetation that plants will not thrive against a creosoted fence or in a creosoted frame. However, there can be little to fear in this respect, since Mr Bridgett affirms that he has employed it with success against American Blight for three years, and even with the addition of clay, as a dressing for dormant vines. I can corroborate Mr Bartlett's statement (p. 50) that this pest frequently attacks young shoots, and is therefore not wholly a wound parasite. There are several cases of it this season in my orchards, notably on Cox's Orange Pippin, Domino, and Early Julyan. In such cases local applications are almost impossible, if only because of the amount of ground to be covered, so spraying becomes desirable. Mr. Brotherston's success with Gishurst Compound (p. 28) is encouraging, and I have heard of other soapy washes being used with good effect. Evidently the solution has to be strong, and very thoroughly applied, for I have the pest badly on trees that were sprayed for other pests more than once, early in the season, with soft soap used at the rate of 1 oz. to 10 gallons of water (half the strength of Mr. Brotherston's Gishurst wash), in some cases with the addition of nicotine. Mr. Theobald states that the blight can be kept in check by winter spraying with the Woburn winter wash, or even with the common caustic soda spray. The latter was tried once on my trees without much success, but I shall try winter spraying again next winter. Unfortunately some of the insects are said to migrate to the roots during the winter, and these would escape. *Market Grower.*

NOTICES OF BOOKS.

Modern Fruit Growing.*

The man who wishes to embark on the growing of fruit for market finds himself in need of information on many points which naturally do not come within the scope of the many books on fruit culture written for the amateur or professional gardener. *Modern Fruit Growing* is intended to supply such information, and it fulfils its purpose admirably. The intending planter could hardly find a better guide. The author, though primarily a nurseryman, has been growing fruit for market for fourteen years, and his father for very much longer; and the advice he gives is obviously the outcome of practical experience. The chapters on the preparation and marking out of the land, the selection of varieties and stocks, pruning, manuring, and the general routine of the fruit farm, are thoroughly sound and practical. The cultivation of the orchard by horsed implements, a matter of great importance now that hand labour is so scarce and dear, is dealt with fully, and the author has some very original ideas on the subject which will well repay the attention of experienced growers. There is a useful chapter on spraying appliances, and another on the drying and bottling of fruits, whilst packing for market, orchard culture, and the storing of fruit receive attention. The subject of finance, which is frequently slurked, is dealt with candidly, actual returns for a number of years being given, together with an estimate of expenses. Mr Seabrook considers that to purchase bare arable land and plant it with trees and bushes requires a minimum capital of £125 per acre under present conditions, but that an early return may be expected from the planting of bush trained trees on dwarfing stocks with soft fruits between them. Experienced growers will find the book worth reading for its original ideas, though it is not expected that they will agree with all the author's statements and practice. *M. G.*

* *Modern Fruit Growing.* By W. P. Seabrook. Pp. 172, illustrated. (The Lockwood Press, 1, Mitre Court, London, E.C. 4.) Price 1s. 6d. net.

ORCHID NOTES AND GLEANINGS.

Lycaste Imschootiana.

Raised by Mr. Alfred van Imschoot, of Ghent, by crossing Lycaste Skinneri with L. cruenta, this hybrid was first shown at Brussels in 1905, and on December 12 of the same year it obtained an Award of Merit at the Royal Horticultural Society's meeting. The ground colour of the original flower was cream-white, tinged with pale buff yellow and spotted with light purple, but varieties subsequently flowered vary in tint and generally are of a lighter shade.

It is interesting to record a fine flower of a natural hybrid Lycaste from the collection of Samuel Gratrix, Esq., West Point, Whalley Range, Manchester, which agrees in every respect with the original Lycaste Imschootiana (p. 27), and plainly indicates that in some parts of Guatemala L. Skinneri and L. cruenta grow together, or near enough to admit of cross-fertilisation by insect aid. The flower sent is well represented by the illustration we give. The sepals are greenish-cream colour, with a yellow shading, and profusely spotted with light purple. The petals are similarly coloured, but show more yellow on the outer halves. The lip bears the deep maroon blotch at the base as seen in L. cruenta, but extended to the back of the yellow callus, which also bears some purple spots. The median part of the lip is yellow, shading to cream white towards the recurved apex. The column is yellow with a band of dark purple at the base.

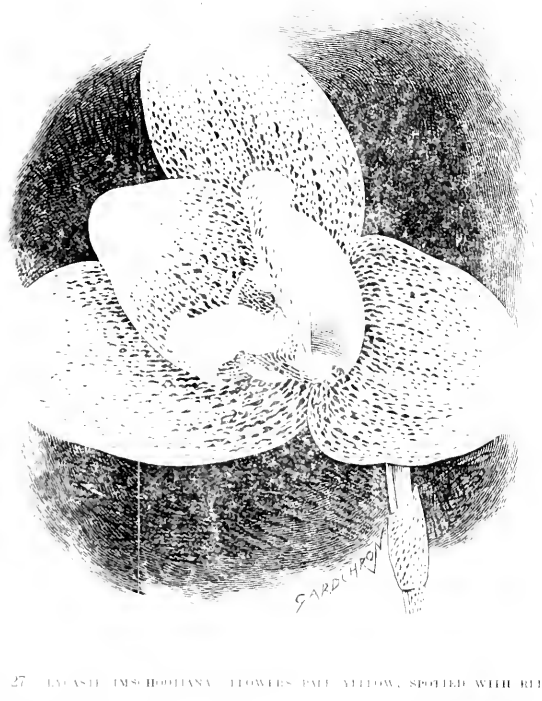

Fig. 27. Lycaste Imschootiana: flowers pale yellow, spotted with red.

BEGONIA PARVA.

Nearly all of the many species of Begonia have a triquetrous winged capsule, the exceptions being a small group of African species in which the capsule is fusiform (spindle-shaped). B. Mannii and B. prismatocarpa are two of these which have been cultivated in gardens for fifty years or more. Several others have been introduced in recent years from the Congo, B. parva (see fig. 28), having flowered in 1912 in the Botanical Garden at Brussels. B. Pogget is another species which we owe to the same garden. The flowers in both these species are produced in the leaf axils, females in threes in summer, males in clusters in late autumn and winter. The branch figured on p. 78 shows only male flowers. They are not particularly showy, their colour being dull rose-red, which is also the colour of B.

Manni. The ovary is about an inch long, pale brown and scabrid. Leaves somewhat coriaceous, smooth above, scabrid beneath. The stems are scandent, and the joints are apt to get leggy and, to a gardener's eye, unsightly. B. luxurians, a Brazilian species, is a handsome scandent plant with Hellebore-like leaves, and is quite useful for training up a pillar or against a blank wall. B. scandens, also Brazilian, is perhaps the only species with climbing stems that has become familiar in British gardens. W. H.

FIG. 26.—BEGONIA PARVA: A NEW SPECIES FROM THE CONGO; FLOWERS DULL ROSE-RED. (See p. 77).

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Spring Cabbage.—Very poor land is not capable of producing good early Cabbages, but heavily manured, deeply dug, loose ground favours rank growth, which must be avoided, as it is unable to withstand severe weather in winter. No site is better for spring Cabbages than the space just cleared of Onions, as the ground is invariably well manured for this crop and will be sufficiently rich and firm to ensure sturdy and hardy growth. Having cleared off the Onions, and any weeds, the ground should have a good dressing of soot and lime worked into the surface with a fork or a Dutch hoe. At least two sowings should always be made, at intervals of a fortnight, as season and soil vary considerably, and it may happen that the earliest raised plants may grow too large to withstand the winter. Extra pains should be taken this season to raise as many plants as possible, as those not now required for planting can be left until the spring, when they will be useful. Plant spring Cabbages 15 inches apart each way, or place them at intervals of 12 inches in rows 18 inches apart.

Lettuce and Endive.—The main supply of Lettuces for early spring use should now be sown, and for this sowing few varieties are so good as Bath or Brown Cos. Some object to the colour of this variety, and prefer Hick's Hardy White, which is also an invaluable Lettuce for autumn sowing. Hardy Green Hammersmith is good and reliable. A small sowing of Early Paris Market and All the Year Round may be made, as these are often ready for use much earlier in spring. Plant Lettuces and Endive in frames for autumn and winter use, and make further sowings of Endive in cold frames.

Potatos.—Early Potatos have been splendid here this year, and the quality of all varieties is good—just the reverse of last year's experience. All early varieties still undug should be lifted on a dry day, and, after being dried, should be stored in small lots in a cool place, and covered so as to exclude light. Tubers required for seed may remain on the ground a few days to green; afterwards spread them thinly in a dry and well-ventilated but frost-proof shed.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Cyclamen.—Old corms which were saved and treated as advised in a previous calendar should now be shaken free from old soil and potted in 6-inch pots. A compost of good fibrous loam, leaf-soil, dried cow or sheep manure, and crushed brick rubble forms an excellent rooting medium. The drainage should consist largely of brick rubble, as the roots of Cyclamen quickly take hold of this material. When potted plunge the pots in ashes in a cold frame, and afford water with great care until new roots have formed.

Souvenir de la Malmaison Carnations.—When the layers are sufficiently well rooted they should be potted firmly in a compost of good fibrous loam, finely crushed brick rubble, wood ashes, and coarse sand. See that the pots are clean and efficiently drained. When potted, give a thorough soaking with water and place the batch in a cold frame. Shade them from bright sunshine for a few days and lightly spray the plants occasionally with rain-water.

Violets.—The propagation of a new stock of plants may be undertaken now, as there are plenty of young shoots suitable for cuttings on the old plants. Place a quantity of fine sandy soil in a cold shallow frame and make it fairly firm. In this insert the cuttings 3 or 4 inches apart, and water them well in. Keep the cuttings shaded from bright sunshine until they have rooted.

and spray them with rain-water twice daily. As soon as rooted they must be gradually hardened off, eventually dispensing with the lights until there is danger of frost. The frames may now be prepared for the plants which are to flower during the coming season. Chop up a quantity of loam and mix with it an equal quantity of leaf-mould: to each bushel add a 6-inch pot full of soot and the same quantity of wood ashes. Elevate the soil so that the plants are fairly close to the glass when planted. After planting, keep the frames almost closed for a few days and syringe the plants twice daily.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to SIR JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Miltonia vexillaria.—Towards the end of the month, many plants of this species and its hybrids will have started well into growth, and at this stage they are very subject to the attacks of small yellow thrips, which hide themselves low down in the axils of the leaves. If these insects are not destroyed the plants will suffer serious injury, and the new growths permanently disfigured. When the pests are found to be present, each plant should be dipped in a solution of Quassia extract, the proportion being half a pint of extract to three gallons of tepid soft water. After they have been dipped, the plants should be laid on their sides to allow the liquid to drain from the leaves without coming into contact with the roots or compost, afterwards rinsing them in clean water. Any repotting necessary should be attended to at this stage. Small specimens and seedlings may be placed in larger pots without much root disturbance, but larger examples which show signs of deterioration should be pulled into several pieces. Cut away dead and useless back pseudo bulbs, leaving only two or three of the latter behind each growing point. Each portion should be placed in a separate receptacle; ordinary flower pots are suitable, and these should be furnished with clean crocks to about three parts their depth. Keep the base of the young growth on a level with the rim of the pot and work the potting material among the roots with moderate firmness. The compost may consist of Osmunda fibre or A1 fibre cut up rather short and freed from all the dusty particles, with a small quantity of chopped Sphagnum moss and crushed crocks. For the present, the plants may be given a position in the cool house, but when the nights become cooler they should be removed to an intermediate house. Water must be applied with great care until the roots extend over the edge of the pot, when the supply may be slightly increased. Shade from direct sunlight, and keep the surroundings moist.

Coelogyne cristata.—Plants of this species and its varieties are making rapid growth, and established specimens will need a copious supply of water at the roots. An occasional watering with a weak solution of liquid cow manure will also be beneficial. Plants which have been potted recently should be watered rather sparingly until the new roots have become established in the compost, and, during the first season after potting, they should be given clear water only.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

The Mixed Border.—The autumnal display should now be perfect, and weekly attention will be needed to keep it in that condition for as long a period as possible. It may seem a waste of time to devote labour to this work every week. On the contrary, it is a saving of time, an hour or two sufficing to remove overgrown parts and faded flowers.

Tender Plants.—The propagation of Verbenas, Ageratums, and Heliotropes may now be effected. Some gardeners give the cuttings the benefit of a little bottom heat, in frames, but artificial heat is not essential. The cuttings should not be large, 2 inches in length being quite large enough, and these root more quickly than longer ones. The cuttings should never be allowed to flag, and if they cannot be handled quickly they should be immersed in water until they can be inserted in the cold frames. The latter must be kept close, damp, and shaded from sun until the cuttings have rooted, then air must be admitted in increasing amount until finally the sashes are drawn off altogether. Where Centaurea ragusina is increased from cuttings, I have found them do best when inserted singly in thumb-pots, placed in a frame ventilated a little night and day, and shaded. Penstemons and Calceolaria amplexicaulis may also be propagated now, and both succeed best when the soil is kept in a very moist condition. It is very important that neither should ever flag, as flagging delays rooting.

Pinks.—Pipings inserted in June should now be thoroughly well rooted, and no time should be lost in planting them in permanent positions. There is ample time for the plants to get established before winter, and if not well pressed down when planted, the soil should be firmly compressed around them in the course of a week or two. Firm soil is not only favourable to growth, for it prevents frost from lifting the plants out of the ground. The commoner varieties, such as Mrs. Sinkins and other border kinds, are easily increased by division.

Forget-me-Nots.—Self-sown seedlings should be transplanted, so that they may be strengthened for spring flowering. Myosotis dissitiflora should be divided, and if the weather and soil are dry, freely water the plants. There is a very pretty Anchusa almost like a Forget-me-Not, which may be divided now if stock is needed. I am not sure that it is quite hardy, but it is a beautiful associate for, though not so glorious as, Myosotidium nobile; its specific name is myosotidiflora.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

Cloches for Late Strawberries. Where late Strawberries are grown it is a good plan to bring cloches into use at this period. These not only assist ripening, but the flavour of the fruits is improved by their use and the crop is safeguarded from birds. Second crops of Royal Sovereign are better finished by this means, and, as the foliage is not so dense now as in the early season, each plant can be conveniently covered by one cloche. A few weeks hence the Perpetual varieties will be greatly assisted if treated in a similar way. When cloches are used it is desirable to raise them slightly, so as to afford some amount of ventilation. Late Strawberries should be gathered rather under ripe than over ripe.

New Strawberry Beds. Make every effort to complete the planting of Strawberries by the end of the month. Runners are now growing freely, and will soon be ready for transplanting. If they are lifted with a fairly good ball of soil and roots they will soon establish themselves. When runners are not in the best condition, place them in three a few inches apart, so as to form small triangular groups. It may not be possible just yet to make new plantations, especially where the ground is heavily cropped, but sufficient runners may be removed and bedded a few inches apart, and watered as necessary until planting can be done. Try, however, to finish the new beds by the end of September.

Early Planted Strawberries.—Those who were fortunate enough to plant Strawberries early, as advised, will have no occasion to regret having made this effort. If the plants make runners, see that these are removed. Keep the ground well hoed between the plants, even if interlocping is being carried out with a vegetable crop, but make the ground firm around each plant before hoeing. I suggest that a trial be made with British Queen Strawberry by planting runners 6 inches apart in rows 2 feet apart.

Seedling Alpine Strawberries. We have at last succeeded in raising a fairly good batch of Alpine Strawberries, but the seedlings will be somewhat small to stand the winter. They will be bedded out until the spring, and then put into their fruiting quarters. Fortunately, we have a good stock of first runners from seedling plants for the earliest batch. These will be planted out this autumn in soil to which leaf-soil has been freely added. Our early beds have quite revived during the past few weeks, and the crop will be overlapping the autumn one. For the summer crop we do not net the beds, but for the autumn crop we do, or the birds would make too free with the fruits.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to MRS. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

Figs.—In a previous article I advised the thinning of Figs in various stages. It is a great temptation to leave all the largest and remove the smallest, but growers who have carried out instructions will now, and for a lengthened period, be gathering a regular succession of excellent Figs from the second crop in the early house. Although the late fruits are not quite so large as early ones, the crop is usually heavy. Daily syringings must now be discontinued, but should red spider be troublesome, the syringe may be used freely on bright mornings once or twice each week, directly all ripe fruits have been gathered. The paths, borders, and stems of the trees may still be syringed during the hottest part of the day, so that all moisture will have evaporated before evening. At this stage a little fire heat is advisable (especially during a spell of cold or wet weather), with a sufficient circulation of air to maintain a warm, buoyant atmosphere. Keep the shoots neatly tied in, and thin them where they are unduly crowded, to permit the ripening of the points that will carry the first crop next year. Keep the border fairly moist, and give an occasional watering with liquid manure directly after all ripe fruits have been gathered.

Late Figs.—The fruits in late houses are developing rapidly. Keep the shoots pinched and tied in to help the fruits and encourage the ripening of the young points. Should fine, hot weather continue, some of the young growths may ripen up a few fruits, but to attempt too much in this direction will keep the trees growing when the wood should be ripening. Moreover, it lessens the chance of securing a good supply of embryo fruits for next year. Abundant supplies of water will be necessary, even if the borders are mulched until the fruits commence to ripen.

Figs in Pots. Pot trees for early forcing that have recently been repotted should be encouraged to ripen their young growths directly they get well established in the new compost. Slightly reduce atmospheric moisture and the water supply, but not to the extent of causing premature ripening of the foliage. Gradually increase the ventilation, and eventually place the trees in the open air, near a wall facing south, there to remain until the end of September, to complete the ripening process. Keep the foliage free from red spider by occasional syringings of weak soot water. Late trees that have been top dressed and are now swelling up heavy crops of fruits will require liberal supplies of diluted liquid manure.

THE APIARY.

By CHLORIS

Extracting Honey. Honey should be left in the hive as long as possible, to ripen thoroughly. The only exception is in districts where Charlock or Mustard grows in abundance, for honey from these flowers soon granulates, and the sooner it is removed the better. If the weather shows signs of remaining cool it will be well to extract all the honey from the combs as soon as removed from the hives, but when the weather is excessively hot it will be an advantage to place the combs in a cool place for 24 hours before extracting the honey. Carry out the operation of extracting in the cool of the evening, to prevent the combs from breaking in the extractor, and so that no bees may collect. The cappings should be removed with as little honey as possible adhering to them, and the same evening placed in cheese-cloth to drain quite dry. Sections are best removed as soon as sealed or they will become stained.

EDITORIAL NOTICE.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER, *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 41, Wellington Street Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, AUGUST 27—

Roy. Hort. Soc.'s, Comm. meet. Joint Comm. R.H.S. and Nat. Dahlia Soc. meet

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 60.5°.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, August 22, 10 a.m., Bar. 30; temp. 80. Weather—Very bright.

The Hibernation of Potato Blight.

The problem of the recurrence year by year of Potato blight (Phytophthora infestans) has vexed the minds of men of science for the last 70 years almost as severely as the blight itself has vexed the minds of growers.

Many different explanations of the perennial nature of the disease have been propounded. The first—that put forward originally by Berkeley in 1846—maintained that the mycelium—that is, the thread-like body of the fungus—is perennial, and maintains itself in diseased tubers, spreading therefrom to the stems. This mode of accounting for the regular recrudescence of the disease was also held by de Bary, who, on the invitation of the Royal Agricultural Society, made a comprehensive investigation of the Potato disease. On the other hand, many investigators refused to be convinced, and put forward opinions, sometimes supported by evidence, tending to show that the fungus produces resting spores which, after remaining quiescent during winter, germinate and re-infest the Potato plant in the following summer. Some confirmation of this view is offered by the recent discovery that Phytophthora infestans, when grown in certain artificial media, produces bodies resembling oöspores, that is the resting spores, characteristic of the group of fungi to which late blight belongs. But in as much as these so-called resting spores have not been discovered in the Potato, the "resting-spore" theory cannot be held to be established. Other hypotheses, as, for example, that the mycelium perennates in the soil, or that the disease is latent in the Potato plant—whatever that may mean—need not be considered here, for they are based on no evidence derived from experiment or observation.

There is no need to insist on the great importance, from the practical point of view, of knowing the origin of our chief Potato trouble, hence it will interest our readers to learn that the most recent investigations appear to demonstrate beyond doubt that infected tubers used as seed serve as the source of origin of the disease in the field. The author of these investigations, Mr. Melhus, first satisfied himself by experiment that the fungus present in naturally infected tubers may gradually extend throughout the tuber, and may reach and infect the eyes so that the sprouts become diseased. The presence of the disease in the sprouts was demonstrated by cutting off the stems and keeping them for 24 hours in moist air, when the fungus produced its characteristic "fruits" or spores.

It was also shown that the spread of the fungus in the tubers and shoots is much more rapid when the sets are kept in moist sand than when they are kept in dry sand; a fact which points a moral no less important than evident that special attention should be paid to the proper drying off of seed tubers, and their clamping. Another noteworthy point is that the fungus spreads rapidly when the temperature of the sand is kept at 16° C. (61° F.), but that it spreads in the tubers little or not at all when the temperatur is kept at 1° to 6° C. (39-43° F.)

The next step in the investigation was to study the spread of the fungus from the tuber to the sprouts. Diseased tubers were planted in sterilised soil and kept at temperatures ranging in the different experiments from 15° C. to 27° C. All produced diseased sprouts. The sprouts of uninfected tubers planted among the diseased sets remained free from the fungus. Not only did the fungus spread from diseased tubers to the shoots arising therefrom, but it produced spores on those shoots, generally near their base. The places on the shoots where this tuber-infection occurred showed the usual and characteristic discoloration and blackening. In one case the fungus was found to spread from the infected shoot for a short distance into the soil, showing that when the conditions are especially favourable the fungus may live for a while in the soil. The early spread of the infection from diseased tubers to sprouts suffices to account for the fact that tubers infected with the disease fail to produce sturdy plants—they are, as it were, born diseased. Particularly notable is the fact that the disease breaks out on shoots from infected tubers below the ground level, so that such shoots which may serve as centres of infection remain dwarf, and readily escape observation. They may be regarded as the incubators of the disease, and the spores which they produce may only much later reveal their effects by an epidemic.

Mr. Melhus was able to show that shoots naturally infected from their tubers do actually produce crops of spores in the field. Experiments in the field also showed that spores produced from mycelium which invades the shoot from the tuber may be liberated, and, falling on neighbouring leaves, establish the disease in them. Further subsequent and extensive field experiments showed that the diseased shoots produced from infected "seed" served to set up an epidemic of the disease throughout the field. This demonstration of the diseased tuber as the starting point of epidemics provides a striking vindication of the garden practice of sprouting seed tubers and rejecting all those which make dwarfed and poorly developed shoots. By this practice risks of planting incubators of epidemics are reduced. In farm practice the problem is far less simple, and will require much more experimental work before it is solved. Nevertheless, it is clear that no care in harvesting and clamping seed Potatos can be too great. When the magnitude of the losses caused by late blight is considered, it will be evident that a few thousand pounds a year spent in systematic investigation would, if it brought forth a practical solution, be recovered many times over in one season.

* "Hibernation of Phytophthora infestans of the Irish Potato," by I. E. Melhus, *Journal of Agricultural Research*, Department of Agriculture, Washington, October 11, 1915, ., No. 2.

Allotments at Bristol.—The Brislington allotment movement had its inception in the Men's Adult School, and commenced with 9½ acres of land obtained through the Bristol Corporation under the Small Holdings and Allotment Act. From this small beginning the Association has grown to a membership of over 1,000 members, cultivating 75 acres of land. A further step in co-operation has been taken by the federation of twenty Bristol societies with 3,000 members.

New Seedling Dahlias.—The joint committee composed of members of the Floral Committee of the Royal Horticultural Society and National Dahlia Society, will meet at the London Scottish Drill Hall, Westminster, at 11 a.m. on August 27, September 24 and October 8, and on September 10, at 10.30 a.m., to consider the merits of any new Dahlias submitted. Awards by the joint committee will carry the A.M. of the R.H.S. and First-class Certificate of the N.D.S.

Fruit for Scottish Jam Makers.—A curious omission was found to exist in connection with the Order confining the supply of fruit in Scotland, unless in small quantities, to jam preservers, in connection with Food Control. Small makers of jam, such as small shopkeepers, were allowed a supply of sugar for jam making proportionate to the quantity they had manufactured in 1915. After the issue of the Order restricting the sale of fruit to licensed jam manufacturers, these small makers, who were not licensed, had difficulty in obtaining their supplies, and special permits had to be granted to enable them to do so.

The Price of Rhubarb Jam.—At a conference of the Food Control Committee of Dumfriesshire and Kirkcudbrightshire, and those of the Burghs of Dumfries and Maxwelltown, held in Dumfries the other day, attention was called to the great disparity between the price paid by neighbouring jam manufacturers for Rhubarb and the control retail price of Rhubarb jam. The Rhubarb was bought at the rate of 9d. per stone of 14 lbs., while the jam is sold retail at 11d. per lb. It was agreed to bring the subject before each of the local committees, and

already a protest has been made by the Maxwelltown Committee. The scarcity of other jam will cause a greater demand for that made from Rhubarb, and the manufacturer may respond extravagant prof

Trichinium Manglesii. A spike of blooms just received of this interesting Australian plant serves as a reminder that the species is suitable for cultivation in a cool greenhouse. Although introduced in 1656, it is by no means commonly met with in gardens, but a well-grown specimen is invariably admired. The spikes of bloom are very persistent, and present a curiously plumose combination of long white hairs and pink or whitish flowers.

Assisting Allotment Holders.—Although the Food Production Department is anxious, wherever possible, that would-be allotment holders should make their own friendly arrangements with the owners of land, its representatives are always ready to assist with advice in any case where difficulties may arise as to the amount of rent to be paid, or other matters. Last week, for instance, in Cheshire, a representative of the Department succeeded in obtaining a reduction of rent from £42 to £32 10s. for seven acres of land held by an Allotment Society. The Department has also been able to arrange for the continuance of tenancy in three instances where notice to quit had been served.

Land Settlement for ex-Service Men.—Recent statements in Parliament with reference to the importance of settling large numbers of soldiers and sailors on the land in this country at the end of the war, and the important recommendations of the Selborne Reconstruction Report, lend special interest to a pamphlet which is being published by the Central Land Association, of 50, Parliament Street, S.W. 1. The pamphlet, free copies of which can be obtained on application by anyone interested, sets out "a proposal for the establishment on a voluntary basis of a county scheme for the settlement of ex-service men on the land." Briefly, the Association proposes that landowners in the different counties should co-operate in providing facilities by which ex-service men can be enabled to obtain land near their own village on easy terms for occupation or purchase. The scheme is intended primarily for men who were agricultural labourers before joining the Forces, and it is claimed that the land problem so far as it concerns them can be handled better on voluntary methods on the lines by local men for local men than by any system of Government organisation. The scheme is set out in a very clear and interesting manner in the pamphlet, and seems likely to attract considerable attention among ex-service men, land reformers, and landowners. County committees are being formed, we understand, under the leadership of the Lords Lieutenant to develop and carry out the scheme.

Parasitic Fungi in Virgin Soil. Experiments in planting Potatos free from disease in virgin soil in Idaho, U.S.A., have shown that the tubers of the crop obtained were often infected with disease. It is therefore apparent that parasitic fungi capable of causing disease in the Potato occur in virgin soil. That this is the case has been demonstrated by Mr O. A. Pratt,* who has isolated from virgin soil three parasitic fungi—two species of Fusarium (F. radicicola and F. trichothecioides), and Rhizoctonia Solani. Further experiments indicate that disease-free Potatos are more likely to be produced on land previously cropped with Alfalfa, Clover, or grain than on virgin land.

A Historic Willow.—Lovers of historic trees will be sorry to learn that it has been found necessary to cut down the celebrated Willow which has stood for many years in the garden of the Spirale Bleue, Paris, and was stated on good authority to have been raised from a cutting of the weeping Napoleon's tomb at St. Helena. The *Revue Horticole*, of November 16, 1917, p. 371, gives an account of this tree, but in the current issue (July, 1918, p. 114) we are informed that the tree was lately found to be unsafe, and had to be destroyed. It was probably planted early in the 19th century by Philippe de Ségur, author of *L'Histoire de Napoléon et de la Grande Armée*, to whom the garden, later made public under its present name, formerly belonged.

Appearance of Onion Smut. Two instances have come to light to-day of the Board of Agriculture's advice young Onions have been attacked by Onion smut Urocystis cepulae, Frostt. This disease has hitherto been met with only once in the United Kingdom, though it is common in America, where it is apparently indigenous. According to Professor Duggar (*Fungous Diseases of Plants*, p. 382), "the host is most frequently shown the presence of the [illegible] precautions to prevent the disease establishing itself in this [illegible]. Young plants which appear to be infected should be carefully examined for any of the symptoms described, and suspicious specimens should be sent to the Secretary, Board of Agriculture and Fisheries, 4, Whitehall Place, London, S.W. 1, packed in a wooden or metal box, which should be labelled "Onion Disease." Directions for [illegible] will be sent at the pressure of the [illegible].

The Trapping of Wild Rabbits.—In many [illegible] districts gardeners are plagued with wild rabbits, and only those who have to manage extensive vegetable and fruit gardens fully understand the damage rabbits are capable of doing to crops, especially during the winter time. One or two methods of trapping rabbits are well known to all who have to do with country life, and now that rabbits have food value these will be used freely, but there are times and circumstances under which ordinary methods fail. To those who care to extend their knowledge of traps and snares we commend the article on "The Taking of Wild Rabbits," by Mr. R. Sharpe, in the

Fig. 24.—Trichinium Manglesii.—Spike of the most flowers past.

[illegible] the first leaf appears. Dusting the seed with [illegible] is also recommended, but these methods have been found to be unsatisfactory when the seed has been examined by the Board's officers, the disease appeared in its early stages as a mere spot or long blush streak, and this darkens in the more advanced stages. The affected part swells as the disease develops and eventually splits, disclosing a large quantity of black spores, like those of the well-known "Bunt" or stinking smut of Wheat. These spore balls are, according to Professor Duggar, washed into the soil if the diseased bulbs are not promptly removed, and the soil is unquestionably the chief source of the annual infection. The spores may also adhere to the surface of the seed, and it is possible that in this way it may have been introduced from America. As Onion Smut causes serious losses in the country of origin, and as it has been ascertained apparently beyond doubt that the spores may retain their capacity for germination in the soil for a period of twelve years, it is of the highest importance that English Onion growers should [illegible] Journal of the Board of Agriculture. Mr. Sharpe sets out in considerable detail the various methods to be employed and how and when to use them most effectively, and [illegible] instructions are accompanied by illustrations there should be no difficulty in following them.

War Item. Mr. James Douglas, gardener to the Rev. B. Douglas Duck, St. Mary's, New Abbey, Dumfries, is informed that his son John, twenty years of age, has been killed in action. This is the third son Mr. Douglas has lost in the war, and another is at present in hospital suffering from wounds.

Nasturtium Wilt. An interesting addition to the bacterial diseases of plants is that of a wilt of Nasturtiums (Tropaeolum majus), described by Mary K. Bryan.* The disease is caused by Bacterium solanacearum, an organism which also affects Potatos, Tomatos, and Tobacco. The disease prevents the blossoming of Nasturtiums, stunts their growth, and quickly kills them. By infection from Tobacco plants

* "Soil Fungi in Relation to Disease of the Irish Potato in Southern Idaho," *Journ. of Agric. Research*, XIII., 2, April 8, 1918.

* *Journ. of Agric. Research*, IV., 5.

suffering from wilt the disease was induced in the Nasturtium, and conversely the wilt of the latter inoculated into Tomato and Tobacco gave rise to the disease in Nasturtiums. Cultivated Ageratums and Verbenas also proved susceptible to wilt infection. This soil bacterium, B. solanacearum, is known to infect plants belonging to the Solanaceae, Compositae, Leguminosae Verbenaceae, Euphorbiaceae, Bignoniaceae, and Geraniaceae.

Oxfordshire School Gardens.—Mr. HEATON'S report to the Oxfordshire Education Committee shows that valuable work in food production has been carried out by the teachers and scholars of the county. Sixty school gardens are reported on, representing an area of 60 acres. The total number of school gardens is 104, and the number of boys and girls who have received instruction is 1,506 and 241 respectively. The value of the produce per acre, reckoned at market rates, is £100. The average yield of Potatos is claimed to have been 22 tons, a fact which will give satisfaction to all advocates of spade cultivation, and add force to Mr. PROTHERO'S apothegm, "God speed the spade." Experiments with "once grown" versus Lincolnshire and Scotch seed show, curiously enough, a slightly heavier yield from the home-grown. We suggest to Mr. HEATON that in continuing this trial next year he should include "twice grown" as well as once grown setts, for it is all important that the advantage of change of seed should be brought home to everyone. From Potato spraying experiments Mr. HEATON is inclined—prematurely as we think—to draw the conclusion that "it appears probable that it does not pay to spray in light soils, but on heavy loams the advantage seems to be worth the expense and labour." An excellent feature of the report is the reference to the teacher's records of pests which proved troublesome; they include Bean Weavils, Carrot Fly, Club-root, Gall Weevil, Onion Maggot and Mildew, Late Potato Blight, Pea Weevil, and Turnip Fly.

Australian Timbers.—Mr. R. T. BAKER, Curator of the Technological Museum, Sydney, N.S.W., is continuing his studies of the timber trees of Australia in the *Journal of the Proceedings of the Royal Society of New South Wales*. "Some Ironbarks of New South Wales" is the title of a recent illustrated paper. The author brings in the anatomical and chemical characters in his classification of the species. "The Ironbark," he says, "is one of the best known groups of trees in the Australian flora, and is especially famous for the hardness, weight, strength, and durability of its timber." Less than a dozen species are known, and they are principally confined to the middle portion of the coastal region of the east side of the continent. Most of the species are well defined. Mr. BAKER adduces as an example of the value of anatomical characters his separation of the different forms associated by writers under the name of Eucalyptus paniculata. These included four distinct woods, and the result of his investigations is the foundation of three new species, which he figures and describes in detail. Mr. BAKER also contributes a paper "On the Occurrence of Crystals in some Australian Timbers." Members of twenty-two families were examined, and of these, crystals were found to occur in the secondary wood of fifteen species, belonging to as many widely different families.

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables in *Gardeners' Chronicle* for August 3, p. 42.)

(*Continued from p.* 72.)

3. ENGLAND, E.

ESSEX. The fruit crop in this district is the smallest I have ever seen. There was a fairly good show of blossom, but owing to cold winds and drought, Apples and Pears are almost a failure in many parts. Plums, Cherries, and small fruits were not so bad, and there was about an average crop of Gooseberries and Red Currants, but Black Currants were very scarce, and Raspberries were dried up for want of rain. Strawberries were very good where well cultivated, but poor under less favourable conditions. *William Johnson, Stansted Hall Gardens, Stansted.*

—— This year's fruit crop is the most disappointing I ever remember. Apples and Plums gave promise of bearing heavy crops, but the warm weather in March on two days we registered 80° in the shade—followed by the arctic weather of April, were probably the chief causes of the failure. Caterpillars on Apple trees have been a worse scourge than ever. Pears bloomed fairly, but the crop is a very light one. Apricots, our best crop, had passed out of bloom before the heavy frosts of April set in. The soil is a strong, yellow clay. *Arthur Bullock, Copped Hall Gardens, Epping.*

HUNTINGDONSHIRE. — Apples are an average crop in these gardens, following a very heavy crop last year. Probably lack of shelter from the north-east wind, which was almost continuous during the flowering time, and neglect of spraying, accounts for much of the failure in this district. Caterpillars destroyed most of the fruits which set. Pear blossom was very scanty on nearly all varieties, and the crop is small. Plums and Cherries flowered well, but most of the flowers were imperfectly fertilised, and only a small proportion of the fruits swelled. Apricots and Peaches benefited by a few warm, sunny days whilst they were in bloom; the flowers set well, and crops were good. Less than half an inch of rain fell here during June, and though Strawberries were plentiful the fruits lacked size and juiciness. Black Currants dropped badly owing to the long drought. Gooseberries, Raspberries, and Red Currants stood the drought better, and bore heavy crops. The Fen soil is peaty over clay, and the high lands a stiff loam, generally also over clay. *A. F. Coombe, Ramsey Abbey Gardens.*

LINCOLNSHIRE.—Apples and Pears are giving very small crops. The only trees that are carrying even an average crop are those which were sprayed in April. Nearly all the Plums failed to set, and the early flowering varieties are the only trees carrying anything like a crop. Strawberries promised well; there was plenty of blossom, but the very dry, hot weather in June and early July checked the late varieties. *F. J. Foster, Grimsthorpe Castle Gardens, Bourne.*

NORFOLK. — Fruit trees of every description blossomed well, but owing to the cold weather they failed to set satisfactorily. Insect pests have been troublesome, and the want of rain has been unfavourable to the few fruits which remained on the trees. Our soil is very light, with a gravelly subsoil. *Isaiah Johnson, Catton House Gardens, Norwich.*

RUTLAND.—Apples, Pears, and Plums looked very promising in early spring, but the blight has completely ruined the trees for this season. *Joseph Robinson, Somerby Hall Gardens, Oakham.*

SUFFOLK.—Unfortunately, what promised to be a record crop of some kinds of fruits has proved to be quite the reverse, and the outlook is very disappointing. Some kinds of Apples in this locality are a total failure. The varieties Ecklinville Seedling and Blenheim Pippin have good crops. The soil being of a very light nature, the drought did much damage. Although the trees were sprayed, caterpillars and aphis were very troublesome. *E. R. Squelch, Manor House Gardens, Bury St. Edmunds.*

4. MIDLAND COUNTIES.

BEDFORDSHIRE.—There is a very poor crop of Apples in this neighbourhood, but what few fruits we have are of fair quality. There are practically no Pears, and very few Plums and Damsons. We had a very good show of bloom on all the trees. We had no frost to spoil the bloom, and I believe the short crop is due to cold, east winds during the blooming season, and also to a lack of bees. Strawberries and Raspberries should have given a good crop, but the long drought spoiled the prospect. *W. H. Neild, Woburn Experimental Fruit Farm, Ridgmont, Aspley Guise.*

—— The fruit crops generally in this district may be described as very poor. Strawberries were good, but the weather was too dry, and they were over very quickly. Plums, Apricots, Peaches, and Cherries set well, but the weather in the last week of April was arctic—in my opinion the worst week of the whole season—which accounts for the failure of these fruits. Apples were not expected to crop especially well, as last year they excelled themselves. Black Currants were fair. Red and White Currants were a failure owing to the trees being devastated by caterpillars. *Thos. W. Stanton, Hinwick Hall Gardens, near Wellingborough.*

BUCKINGHAMSHIRE. — This is a most disappointing season for fruit crops. The late spring frosts, snow, and hailstorms destroyed the greater part of all kinds of fruit tree blossom, and the subsequent drought completed the destruction of the Strawberry crop. Mildew and insect pests are rampant, and both Apple and Pear trees look extremely unhealthy. For want of skilled labour it has not been possible to deal properly with such conditions. Our soil is a heavy, retentive loam, resting on clay, and the natural drainage is bad. *W. Hedley Warren, Aston Clinton Gardens, Tring.*

—— Apple and Plum blossom was very plentiful, but the east and north-east winds did much damage to those flowers and young fruits which escaped the late frosts. Aphis attacks were very persistent. Hardly any Pear blossom developed. The drought during June was trying for Strawberry and Raspberry plants, but copious waterings were effective in securing heavy crops of well-flavoured fruit. *G. F. Johnson, Waddesdon Gardens, Aylesbury.*

—— The fruit crops in South Bucks are almost a failure. A cold spell during the time when Plums were in flower spoiled what otherwise might have been a good crop; the flowers were strong and there was plenty of pollen. Pears are almost a complete failure; a few varieties have a small crop of clean-looking fruits, e.g., Williams' Bon Chrétien, Beurré d'Anjou, President d'Osmanville, and Marguerite Marillat. Apples are perhaps the best crop, and Grenadier and Lord Grosvenor are carrying heavy crops, but late culinary varieties are scarce. Aphis is very prevalent and difficult to destroy. *Chas. Page, Dropmore Gardens, Maidenhead.*

CHESHIRE.—The Apple trees without exception showed plenty of bloom, but very few fruits set, and the crop is the lightest for a number of years, except for a few young trees that were planted in February, 1917, and these are carrying a good average crop. Pear trees showed very little bloom, and the crop may be regarded as a complete failure. Plums were laden with bloom, but there are few fruits. This is probably due to inclement weather when the trees were in bloom, following a mild winter, and to the infertility of the pollen. Most

of our Apple and Pear trees are about 15 years planted, on a fairly light soil, the base of which is sandstone, and at an elevation of 100 feet above sea level, well exposed, and mid-way between the Cheshire and Derbyshire hills. *N. F. Barnes, Eaton Gardens, Chester.*

—— Early in the season there was a prospect of good crops, but severe frosts and keen, cold winds during the flowering period of Apples, Pears and Plums, prevented them from setting their fruits. With the above exceptions, we have fairly satisfactory crops. All kinds of insect pests have been very troublesome, especially the Apple maggot. *Charles Flack, Cholmondeley Castle Gardens, Malpas.*

—— This year's fruit crop is the worst we have had for many years. The cold, damp nights, together with the morning frosts of April and May, contributed largely to bring about this unsatisfactory state of things. *Alfred N. Jones, Marbury Hall Gardens, Northwich.*

DERBYSHIRE.—Taken generally, hard and soft fruits are under the average crop here. There are few Pears. Apples and bush fruits suffered from north-east winds just when the Apples were flowering; some trees were a blaze of bloom, but only a fair crop set. The soil is medium loam with a clay subsoil. *F. G. Mills, Lonvside Home Farm, Glossop.*

—— Our Apple trees were rendered leafless by a plague of caterpillars. The trees have made new growth, but there seems little prospect of a crop, even next year. The Damson crop is very poor. *E. Wilson, Hardwick Hall Gardens, Chesterfield.*

HERTFORDSHIRE.—The fruit crops generally are the most unsatisfactory experienced during my period at Aldenham. Apples promised well; the majority of the trees flowered profusely, but the individual flowers were poor, opened late, and failed to set. Plums likewise flowered abundantly, but severe snow-storms at that period accounted for their failing to set. Pears, on the contrary, showed very little flower, and the crop is a complete failure. The long continued spell of drought has had a serious effect on the fruit trees generally, and in spite of thorough spraying they are badly infested with caterpillars, aphides, and American Blight. Many of the small fruits dried up. Apricots and Peaches, on the contrary, are good. There are heavy crops, and the trees are wonderfully clean; there is no sign of leaf curl on the Peaches and Nectarines. Our soil is stiff London clay. *Edwin Beckett, Aldenham House Gardens, Elstree.*

To be continued.

HOME CORRESPONDENCE.

(The Editor do not hold themselves responsible for the opinions expressed by correspondents.)

Preserving Eggs and Fruits.—The method which you record on p. 61 of preserving fruits by immersing them in very hot water recalls the fact that, many years ago, before waterglass was commonly known, my mother always preserved hens' eggs during the early summer for winter use by a similar process. They were placed in a Potato-net and immersed in quite boiling water for a moment, then wrapped separately in paper and placed in a box of clean, dry sawdust until required. By this means the eggs kept quite good throughout the winter, indeed, they were so good that it was difficult to distinguish between the preserved and newly-laid eggs. The principle in each case seems to be the same—the closing of the air-spaces in the epidermis—only with the eggs it was effective for a longer period. *A. C. Barlott.*

"Rogues" Among Potatos.—I have just been re-perusing your account of Mr. Cuthbertson's lecture on "Potato Growing, Spraying, Lifting, and Storing," in your issue of June 29, 1918, p. 261. He says: "When growth is sufficiently developed it is possible to detect the 'rogues,' or plants not true to name, by the difference in the foliage or the colour of the flowers. Such rogues should be marked with a bamboo cane for removal." What, then, after removal? These "rogues" are usually very inconsiderately treated, for some of them are entirely new sorts, produced from the tuber itself, without seed-bearing, and deserve better treatment than common consumption. They should be grown separately, to see if they show any advance on known sorts. The Potato, like many other plants, has the power to produce new sorts vegetatively apart from seed. *S. Jackson, Arley, Port Hill, Shrewsbury.*

Vegetarians and Food Control.—It has generally been recognised that the arrangements made by the Food Controller regarding the distribution of meat and fats have pressed hardly upon those who, either from principle or for other reasons, are unable to avail themselves of the meat rations allowed to the public. This hardship has been intensified by the additional quantity of bacon made available. As the regulations have hitherto stood, a vegetarian could only receive a fat ration of 4 (or lately 5) ounces of butter or margarine. Under a doctor's certificate he might obtain an additional quantity of butter or margarine, but this was not supposed to be granted except for certain specified diseases. In consequence, most vegetarians were compelled to be satisfied with a very small quantity of fats, and complaints were made regarding this. By a lately issued Meat Rationing Order (M.G.R.M. 53), an attempt has been made to meet the complaints, but it must be said that it is not a successful one. Under it an adult surrenders his meat card and receives in exchange authority for one extra fat ration for the week. The same Order contains instructions regarding Jews, who do not eat bacon, and who have only to surrender two bacon coupons out of their four meat ones to secure an additional allowance of fats. This is an example of the many anomalies which still exist in connection with food rationing, which has, on the whole, been fairly planned. It seems to be a case in which vegetarians should make their voices heard in order that their needs should be fairly met. (*Vegetarian for Health Reasons.*

Scientific Committee.

JULY 30. *Present:* Mr. E. A. Bowles, M.A., V.M.H. (in the chair), Messrs. J. W. Odell, F. M. Holmes, W. Fawcett, J. T. Bennett-Poe, W. C. Worsdell, J. Fraser, and F. J. Chittenden (hon. sec.).

Specimen of a Newt.—Mr. Bowles showed a case of tetal-tors on the stem of the common cattle-Vetch, sent from Sir Hugh Beevor's garden at Hargham.

The "Thorn Apple."—Mr. Worsdell showed further examples of the so-called Thorn Apple from Dorsetshire, demonstrating the change of both stamens and petals into fleshy structures in the formation of the fruits, which externally show only the edges of these structures. The tree constantly produces these curious malformed fruits.

Fasciated Vegetable Marrow.—Mr. Odell showed an example of fasciation in Vegetable Marrow in which three flowers took part. They were all staminate.

Fruit of Chimonanthus fragrans.—Mr. Fraser showed a fruit of the "Winter Sweet" planted in this country.

Various Plants.—Mr. Hay sent specimens of the following uncommon plants: Antirrhinum Coulterianum and Linanus Gravi from California; Saxifraga fimbriata from the Himalaya; a deep-coloured form of Impatiens Roylei; Meconopsis latifolia with incipient doubling.

AUGUST 13. *Present:* Mr. E. A. Bowles, M.A., V.M.H. (in the chair), Dr. Rendle, Col. Rawson, Messrs. J. W. Odell, W. C. Worsdell, E. J. Allard, J. Fraser, and F. J. Chittenden (hon. sec.).

Trigonella cærulea.—Mr. J. Fraser showed a specimen of this plant, which has a very persistent odour somewhat like that of curry. It is a native of Southern Tyrol and Italy, and is said to be used for giving scent to cheese and for spicing cattle cake.

Doubling of Tropæolum.—Col. Rawson showed some examples of Tropæolum with sepals from the calyx adjacent to the spur, where petaloid growths had been produced bearing an anther (or part of one) on their margins. He considered that this might be the beginning of the doubling of the flower. Mr. Allard pointed out that there were two forms of double Tropæolums arising from different kinds of multiplication of parts.

Plants from Palestine.—Mr. Odell showed examples of Marrubium vulgare, Verbascum Blattaria, and a species of Nigella raised from seed sent from Palestine. The last was not recognised, and Dr. Rendle took it for further examination.

Rubus sp.—Mr. Bowles showed a species of Rubus, a chance seedling in his garden, and probably of Chinese origin, with palmate leaves, white tomentose beneath, and drooping clusters of large black fruits. Dr. Rendle also took this for further examination.

Damage by Hail.—The Rev. W. Wilks showed a specimen of Vitis with the foliage perforated by hailstones in a recent storm at Shirley, and the stem with large warts resulting from damage from the same agency.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

AUGUST 12.—The monthly meeting of this Society was held in the R.H.S. Hall, Mr. Chas. H. Curtis presiding. Three new members were elected. Two members withdrew interest amounting to £7 0s. 8d., and two members withdrew £42 0s. 5d. from their deposit accounts. The Army Forms relating to the deaths of Rfn. W. J. Gibson, Pte. G. A. P. Bentley, Pte. C. Maunder, Lance-Corporal R. J. Bird, Rfn. J. M. Green and Pte. F. C. Wootton were produced, and the sum of £20 16s. 1d. was passed for payment to their respective nominees. The sum of £21 19s. 7d. was also passed for payment to a lapsed member. The sick pay for the month on the ordinary side amounted to £66 6s. 3d., and in the State Section to £20 3s. 4d., while maternity benefits amounted to £6.

The Committee wishes to remind members that they must now notify the secretary on the day of incapacity; sick benefit is not payable retrospectively unless a satisfactory reason for delay is given. Any members wishing for a further supply of forms for junior membership can obtain same from secretary.

SCOTTISH HORTICULTURAL.

AUGUST 6. The monthly meeting was held at St. Andrew Square, Edinburgh, Miss Burton, vice-president, in the chair.

Mr. J. S. Brunton, Barnbey, gave an interesting lecture on "Horticulture in the United States" as he saw it recently on an extensive tour through the country. He dealt with it under the following heads: (a) public parks, (b) private gardens, and (c) commercial establishments. An account of the damage done by the Huns to nursery establishments in Belgium was given by M. Boackenooghe, a nurseryman at Ypres, whose premises were completely destroyed, and who is at present residing in England. Exhibits of Potatos, etc., were set up by Messrs. Dobbie and Co. and Miss Burton; of Campanula pyramidalis by Mr. T. W. Scarlett; and of Physalis edulis by Mr. J. Bruce, each of whom received a Cultural Certificate.

TRADE NOTES.

THE premises and goodwill of Messrs. W. Wells and Co., Chrysanthemum and Carnation growers, Merstham, Surrey, will be offered for sale by auction, as a going concern, on September 3, at the Market Hall, Redhill. The sale is under the instructions of the trustees of the late Mr. William Wells, and in pursuance of the direction to that effect in his will. The premises include 6½ acres of land, a freehold cottage, and 17 glasshouses.

UNDERSIZED APPLES.

The Food Controller has issued a Temporary Order which provides that no Apples capable of passing through a 2 inch ring—with the exception of Beauty of Bath, Bismon, Ben's Red, Cox's Orange Pippin, Devonshire Quarrenden, Lady Sudeley, Miller's Seedling, Yellow Ingestre, Duchess's Favourite (Duchess of Gloucester), Duchess of Oldenburg, Feltham Beauty, Mr. Gladstone, Longacy Pippin, Worcester Pearmain, Hunt's Early, Irish Peach, James Grieve, Junouting (Red and White), and King of the Pippins (Prince's Pippins)—shall be sold or delivered or offered for sale or delivery in the United Kingdom, to any person other than a licensed jam manufacturer, or to a licensed dealer who undertakes to sell to a licensed jam manufacturer. The grower's price for such Apples is £12 per ton. Dealers are allowed to add a commission of 12s. 6d. per ton, and provision is made for packages and tolls on the lines of the Plum (Sales) Order.

This Order will be followed by another dealing with the whole question of the sale and distribution of Apples, after the Board of Agriculture has consulted with representatives of the fruit growers.

COVENT GARDEN MARKET.

We understand a private company has been formed to administer the Covent Garden Market estate, which has now passed out of the hands of the Duke of Bedford. The new company consists of Mr. C. F. Boston (chairman) and Dr. F. D. Woolley (sons-in-law of the late Sir Joseph Beecham), Sir Thomas Beecham, and Mr. Henry Beecham. The solicitors to the estate are Messrs. Russell, Cooke and Co., London, and Messrs. Bremner, Son and Corlett, Liverpool.

CROPS AND STOCK ON THE HOME FARM.

Rye.

For sheep food in April, before the Vetches or Trifolium are ready for use, Rye fills a gap, and if not required by reason of good late Turnip and Swede crops, Rye is useful for seed and for milling. The straw from Rye is valuable for thatching, especially for buildings, lying closer than Wheat straw, and therefore making a more lasting roof, besides being neater in appearance.

September is the best month in which to sow Rye; sow at the rate of 3 bushels per acre on a well prepared surface, following Wheat; on a clean stubble plough once to bury the stubble and weeds thoroughly, then harrow and roll to obtain the necessary tilth.

Winter Barley.

Winter Barley is a most valuable sheep food in a green state, and if not required for sheep it can be allowed to ripen and be used for seed, or for pig food if released. Winter Barley ripens early, and permits an early start in harvesting, which is an advantage where a large acreage is under cultivation.

Potatos.

Early varieties have produced heavy crops of clean, good tubers that sell at a reasonably good price. The favourite variety in this county is Epicure. Although a second early, it grows so quickly and yields so heavily that it is employed mainly as a first early. Its cooking qualities are much improved by early use, and its proper season is August. Sharpe's Express and Eclipse are also favoured by many growers. British Queen is popular as a second early, cropping well, and when dug early it is not liable to disease. Home saved sets of early or second early Potatos should not be left in the ground too long; lift and allow them to lie on the ground until thoroughly dry and partially green, and then place them thinly in boxes and store in a cool shed. Care in selecting the tubers is important; retain shapely, sound examples, weighing about 2 oz. each.

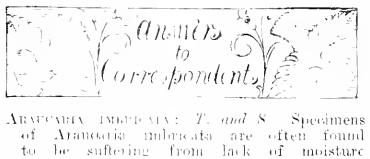
There are signs of Potato disease in many gardens, especially where the crop was not sprayed, and the sets were planted closely together. Overcrowding certainly helps the spread of the disease. Late varieties, like Iron Duke, Arran Chief, King Edward, and Up-to-Date, which have been sprayed twice, look wonderfully well. A third spraying, it contemplated, should be given at once. Even with a big plot of 20 acres it is not so difficult a matter to spray with a horse machine as some would have us believe; this work can be done easily in two days by a quick horse.

Vetches.

Vetches form a valuable crop for sheep, horses and cows, when grown under favourable conditions. If not required for feeding it will pay to save the seed. In that case the crop should not be sown quite so thickly, as, when the plants are not crowded, the pods are more freely produced, and that is the main object when growing Vetches for seed. When grown for feeding it is bulk of growth that is desired. For seed purposes 1½ bushel of seed per acre is ample; for feeding purposes add another ½ bushel of seed. Any clean stubble, once ploughed and harrowed, will provide a suitable tilth. Drilling is the best method of sowing, as all the seeds are then buried, and not exposed to the depredations of pigeons and rooks. The surface need not be made too fine, as small clods act as a slight protection during the winter months, and they are easily pulverised by rolling in spring. *E. Molyneux, Swanmore Farm, Bishops Waltham, Hants.*

Obituary.

Frank N. Meyer.—News comes from America of the death of Mr. Frank N. Meyer, explorer for the Washington Board of Agriculture, whose body was found in the Yangtse-Kiang River in China without any evidence of the cause of death. Mr. Meyer had made many journeys to Siberia, Manchuria and China in the search for new fruits and vegetables, and an interesting account of his travels and discoveries will be found in a recent report of the Board of Agriculture of Washington. Among the interesting plants which Meyer introduced to America were a wild Peach, possibly the prototype of our cultivated varieties, many varieties of Persimmons, Jujubes, Citruses and Bamboos, all of which offer great possibilities for certain climatic conditions in the United States. Meyer was one of the most modest and unassuming of men, and when he could be induced to speak of his adventures one could only be surprised that so small a body held so courageous a heart. He will be sadly missed by those who knew him, but he will be remembered by gardeners for many generations as the fruits of his work mature and develop.



Araucaria imbricata: *T. and S.* Specimens of Araucaria imbricata are often found to be suffering from lack of moisture or from semi-starvation. When the lower branches show signs of turning brown the soil should be examined for the purpose of discovering whether more moisture is needed or not. If the soil is poor, remove a few inches from the surface of the area occupied by the roots and supply a compost of loam and old manure, followed by a mulching of manure. If this treatment is not possible provide a mulching of rich manure, and, if necessary, supply water, allowing it to pass through the mulching. Mud dredged from a pond or lake makes a suitable top-dressing for such trees, and may be used in the absence of manure.

Bedeguar Gall on Rosa lucida: *J. P.* The only point unusual about the gall sent is its appearance at the extreme tip of a short growth produced at the base of the plant. See answer to *G. E.*, p. 74.

Crops and Stock for a 50-acre Holding: *B. H. W.* Of the 25 acres of pasture, 10 acres should be cut annually for hay, changing the fields and feeding them alternately; the aftermath should also be fed off yearly. Crop 5 acres of the arable land with Oats, to provide straw for winter use, and corn for one horse; put 3 acres under Mangold for cattle, and plant the remaining 2 acres with Potatos, early or late varieties, according to the requirements of the neighbourhood. One or two cows should be kept for private use to provide milk and butter. We also advise the purchase of two-year-old Shorthorn heifers of good quality, to calve in the autumn when they are three years old, as such stock sells well at that season. The number should be regulated by the quantity of grass provided by the fields, but if of poor quality the grass could be improved by the application of basic slag in the autumn. One handy permanent man would suffice, with casual labour for haymaking and for hoeing the Mangold and Potato crops. One horse would suffice, with the hiring of a second horse occasionally, or the main work of ploughing, etc., could be carried out under contract.

Insect Pests on Peach Leaves: *D. C. H.* Dry soil around the roots and a dry atmosphere in the house have combined to encourage red spider and thrips, two minute insect pests which always seem to be lying in wait to attack Peach and vine foliage. The leaves sent give evidence of very bad attacks, consequently drastic measures must be taken to clear the foliage. Fumigating and vigorous syringing with a nicotine or similar insecticide should soon effect a clearance, but all parts of the tree and structure should be treated with the insecticide, and also with clear water. See that the border is thoroughly moistened, and take care that the Peach foliage is dry before fumigating the house in the evening; syringe with clear water early in the morning, after fumigating. Fumigate the house on two successive evenings, then use insecticide at intervals of two days.

Names of Fruits: *A. O. S.* Hales' Early.—*J. C. F.* 1, Worcester Pearmain; 2, Devonshire Quarrenden; 3, Duchess of Oldenburg.—*W. R. C.* 1, Muscat of Alexandria; 2, Lady Downe's Seedling.

Names of Plants: *E. S.* Hypericum moserum. *S. B.* Carlenia benedicta.—*J. K.* 1, Monarda didyma; 2, Inula glandulosa; 3, probably Solidago rugosa (send again); 4, Physalis capensis; 5, Spiræa japonica var. Bumalda; 6, Polygonum amplexicaule; 7, Centranthus ruber; 8, Eupatorium cannabina; 9, Viburnum Lantana; 10, Solidago virgaurea.—*I.* 1, Hemerocallis flava; 2, Sedum Telephium var.; 3, Tradescantia virginica; 4, Veronica spicata; 5, Euphorbia cyparissias; 6, probably Myosotis palustris (should have been sent when in flower).—*C. M. P.* 1, Pyrus Aria; 2, Bignonia radicans; 3, Picea excelsa var. Clanbrasiliensis.

"Rust" on Tomatos: *R. B. S.* The disease on the Tomato leaves is known as Tomato-leaf Mould, or Tomato Rust (Cladosporium fulvum). Remove and burn all badly diseased portions of the plants and spray the remainder with weak Bordeaux mixture or with a weak solution of sulphide of potassium. Wherever this disease has appeared previously the Tomato plants should be sprayed, as a preventive measure, while quite young.

Scarlet-fleshed Melon: *S. A.* The scarlet-fleshed Melon is most probably a local seedling. It is somewhat like the variety named King George, but hardly so handsome, though the depth of flesh and the flavour are both first-rate. We suggest you give the variety a provisional and local name and send a few seeds to the Superintendent, R.H.S. Gardens, Wisley, so that the variety may be tested with others.

THE PROGRESS OF VEGETABLE CULTURE.

APART from the great stimulus in the cultivation of vegetables due to circumstances connected with the war the importance of vegetable growing has been more fully recognised during the last two decades than in any earlier period. The kitchen garden was at one time looked upon as the Cinderella of the establishment, and even head gardeners regarded the matter of vegetable cultivation as of only secondary importance. It is not very long ago that men skilled in the work were difficult to obtain; under-gardeners especially were loth to take up this side of their profession, and seemed to regard the indoor departments as the special aim and object of all successful gardeners. I remember the time when out of every three candidates for a position in the kitchen garden only one on the average had any real knowledge of vegetable culture. Not only was this true of journeymen, but it was probably more so of foremen. All this tended to retard progress, and another matter which had a similar effect was the contempt with which exhibitors of vegetables were regarded by those who were showing fruits and flowers. This was due to a belief that vegetable exhibitors showed their products only for the sake of the prizes; and this apparently was the view also of organisers of horticultural exhibitions, at one time judge by the way in which vegetable exhibits were thrust into the background and handicapped in every way. All this is now changed, and, as a result of the gradual improvement which has taken place, owing to the efforts of a few vegetable enthusiasts, the proper status of vegetable exhibits in any horticultural exhibition is now fully recognised. In recent years growers have begun to realise that there is as much fascination and interest in producing good vegetables as there is in cultivating rare and choice flowers or luscious fruits. The advance is also partly due to exhibitions, for the habitual exhibitor must be ever on the alert to obtain superior varieties as well as high-class produce.

It is sometimes urged that a grower of exhibition vegetables is less capable of providing an establishment with produce of everyday quality than the ordinary gardener; but this is a fallacy. The man who produces the best exhibition produce excels also as a grower for home requirements.

Not only is progress observed so far as it concerns professional gardeners, but the public also takes a great interest in the matter, and the daily news papers frequently organise vegetable shows at which they offer valuable prizes to amateur growers.

In past years enormous quantities of Potatos and Onions—to mention only two staple vegetables—have been imported from abroad, and in future we may have to depend more and more on our own efforts in raising food, and there seems no reason why we should not be entirely self-supporting in these matters. But in order to attain this, something more is needed than merely to plough or dig up a piece of land and expect to reap a rich harvest. The cultivator must not only enrich his soil with a view to getting it into a good condition, but cleans it if necessary, and in such a case ultimately obtains much greater success than his less careful neighbour. In this district there are two or three fields which have received such careful treatment as I have outlined, and although they were only rough pasture lands a few years, they are now carrying some of the finest crops it has ever been my good fortune to see. Another matter in which it behoves growers to exercise careful forethought is the selection of crops for certain sites, and of varieties for planting. Often, for example, one sees a large area of ground planted with Carrots although it is totally unsuitable for such a crop. Such a procedure can only end in failure. In the selection of suitable varieties the grower should be guided by the success or failures of his neighbours, for it is well known that certain varieties as well as certain kinds of vegetables do well in one district, are unsuccessful in others.

It may be urged that the amount of land suitable for vegetable cultivation is somewhat limited, but there is no reason why even poor pasture land, which is almost unremunerative to the grazier, cannot be improved by spade cultivation and manuring, and made to produce excellent crops of vegetables. All this requires hard work, but those who possess such inferior land must be roused to action. Moreover, such details as the trimming of hedges and the eradication of weeds must be enforced in the common interests of all. Choked and rat-infested ditches must be cleared out, and made to serve their proper purpose of draining the land.

Hand in hand with the improved cultivation of the land must come the creation of improved varieties. There is no doubt that one of the greatest aids in this matter is the exhibition, which leads growers to strive after improved quality, and to seek for varieties which are either earlier or later than the normal kinds, and will thus tend to lengthen the season.

It is apparent to all that much progress has already been made, and it may be expected that, in view of the stimulation of interest in vegetable growing which has been brought about through the war, this progress will be maintained. It is earnestly to be hoped that in the somewhat easier conditions which will follow the making of peace, the lessons thus learned will not be forgotten. *Edwin Beckett, Aldenham House Gardens, Elstree, Hertfordshire.*

ORCHID NOTES AND GLEANINGS.

CATTLEYA HELEN LANGLEY

A FLOWER taken from the plant of this pretty hybrid which obtained a First-class Certificate at Manchester in December last, is sent by J. B. Hurst, Esq., The Knowle, Morley, Yorkshire. The hybrid was obtained by crossing C. Dusseldorfer Undine (intermedia alba × Mossiæ Wagneri) and C. Mrs. Myra Peeters (Gaskelliana alba × Warneri alba), all its ancestors being albinos a character which is continued in the present hybrid. The flower, which equals those of C. Warneri alba in size, is pure white, with the slightest shade of primrose-yellow in the centre of the lip which is beautifully crimped and fringed at the margin. This and the many other choice, pure white Orchids that add to a section hitherto more or less rare, amply testifies to the utility of the hybridists' efforts.

NOVELTIES FROM CHELTENHAM

MESSRS. JAS. CYPHER AND SONS, Queen's Road Nurseries, Cheltenham, have sent flowers of some of the handsome Orchids now in bloom at their nursery. Laelio-Cattleya blenheimensis is represented by fine forms measuring nearly 9 inches across, and showing a great variation in point of colour in the different varieties. The cross is between Cattleya Warscewiczii and a fine form of Laelia tenebrosa, the latter obliterating the yellow lines and disc of the lip of C. Warscewiczii and resulting in a self-coloured bloom with darker veining. The sepals and petals of one extreme variety are light mauve, and in the other the sepals are pale buff-yellow and the petals cream-white with a pale buff shade.

The species entering into the composition of the richly-coloured Laelio-Cattleya Hesta (C. Peetersii × L. C. Rubens) are Cattleya Dowiana aurea, C. Warscewiczii, C. crispulosa, and Laelia purpurata. The flower is of good form and fine substance, the sepals and petals having a rolled gold gloss, fringed and veined with purplish rose. The lip is dark velvet colour with orange lines at the base.

Cattleya Albion (Suzanne Hye de Crom × O'Brieniana alba) is a beautiful pure white flower, having a chrome-yellow disc to the lip.

Cattleya Snowdrop is a new cross resulting from C. O'Brieniana alba and C. intermedia Aquinii (Mossiæ Wagneri × Warneri alba). It is one of the finest of the white C. O'Brieniana crosses, of excellent shape and fine substance. The sepals and petals are tinged lilac and the flower is wholly pure white with a small yellow disc in the centre of the lip, which is unusually broad for this section.

Cattleya Wavriniana (Warscewiczii × granulosa Schofieldiana) was originally raised by Messrs. Peeters, of Brussels, and named in honour of the late Marquis de Wavrin. The

variety of this interesting link with Continental gardens, which gained a First-class Certificate at the Royal Horticultural Society, was described in the *Gardeners' Chronicle*, July 26, 1902, p. 65, and the flower now received is equal to the best form, measuring 7 inches across, in colour light rosy mauve, the labellum being finely veined with violet-purple.

Messrs. Cypher also send a flower of a large globular white Anguloa, purchased as Anguloa species, which is near to the *A. eburnea* of *Williams' Orchid Album*, III., t. 133, and is referred to in Veitch's *Manual of Orchidaceous Plants* as *A. Clowesii eburnea*. It seems to differ from *A. uniflora* by its larger size and more highly developed labellum.

COELIA MACROSTACHYA

This graceful Orchid (see fig. 52) was discovered by Hartweg in 1841 at the Hacienda de la Llaguna, Mexico, and plants were sent by him to the Royal Horticultural Society's Garden at Chiswick, one of the specimens flowering in the collection there in 1849. Probably in consequence of ill-developed material, Lindley did not appear to be much impressed by the beauty of this Orchid (*Gen. Plant.*, Sup., IV., pp. 114, 155, with figure). In 1853 a specimen sent from the Belfast Botanical Gardens was illustrated in the *Botanical Magazine* (t. 4712), the late Sir Joseph Hooker remarking: "It is a pretty and handsome plant, and well worthy of a place in every Orchidaceous collection, flowering in August."

Since that time the presence of fine specimens of *Coelia macrostachya* in many gardens, and in collections of Orchids staged at floral exhibitions, amply warrants the estimate of the eminent botanist, and at present, when the cultivation of not a few of the showiest species has declined, the species still commands attention.

The plant is compact and dwarf in habit, its oblong pseudo-bulbs being furnished with arching, parallel-ribbed leaves a foot or more in length. The stout scapes, which are as long as the leaves, have the basal part clothed with large, ovate, acuminate, brownish sheaths, the upper part consisting of a dense spike bearing numerous flowers with somewhat incurved segments, rose-coloured on a silver-white ground, the petals being paler than the sepals, and each flower furnished with a linear, acuminate bract.

Coelia macrostachya thrives well in the intermediate house. It should be treated similarly to *Zygopetalum Mackayi*. A goodly proportion of the potting material should consist of fibrous yellow loam. The atmosphere and temperature suited to the Mexican Laelias, with the reasonable amount of sunlight admitted to those plants, suit the Coelias.

Two other species are sometimes seen in gardens, *Coelia Bauerana* (*triptera*), smaller but of similar habit to *C. macrostachya*; and *Coelia bella*, which has short, few-flowered spikes of white flowers 2 inches long, the sepals tipped with purplish rose. The latter is a fragrant and pretty species.

Fig. 50.—Coelia macrostachya: flowers white.

Photograph by C. P. Raffill.

TREES AND SHRUBS.

FOTHERGILLA GARDENII

(Syn. *F. alnifolia*).

Although introduced many years ago, this deciduous shrub (see fig. 50) has never become common in gardens. It is perfectly hardy so far as its capability of withstanding our severe winters is concerned, but it is evidently in some way lacking in robustness, otherwise it would not be so scarce. Being only 2 or 3 feet high, and not a very vigorous grower, it is unfitted for the ordinary rough shrubbery; but if it lacks the self-assertion necessary for such a position, there are few more charming plants for a border of select and carefully tended shrubs. Its blossoms in spring, the inflorescence having a bottle-brush appearance owing to the length of the white stamens, which, petals being absent, form the only conspicuous part of the flowers. The greatest beauty of this Fothergilla is, however, apparent in autumn, when its leaves turn a rich, glowing red. It is a native of Eastern North America, and the generic name was given in honour of Dr. John Fothergill, famous in the later years of the eighteenth century for his botanical collections at Upton, in Essex. Another species—*F. major*—has lately come into prominence. It is a larger and more robust shrub than *F. Gardenii*, and grows 8 feet high. It is better as a flowering plant, but it lacks the rich autumnal glow of *F. Gardenii*, its foliage turning yellow. *F. Gardenii* enjoys a light loam, and grows all the better if peat and leaf-soil are mixed with the loam at planting-time. *W. J. B.*

EUCRYPHIA PINNATIFOLIA

Among the shrubs or small trees that flower during the month of August, Eucryphia pinnatifolia occupies a prominent position. It is of somewhat erect growth, the pinnate leaves, which consist of 3 to 5 leaflets, being of a dark, shining green. The flowers, which are freely produced, are about 2½ inches across, and composed of four petals of the purest white. The centre of the flower is quite filled with the long, prominent stamens, tipped with golden anthers. From this circumstance the bloom bears a certain resemblance, except in colour, to that of a Hypericum. There is a double-flowered form (see fig. 51), which originated as a seedling in the gardens at Castlewellan, Co. Down. Eucryphia pinnatifolia was first introduced by Richard Pearce, of tuberous Begonia fame, while travelling in Chili on behalf of Messrs. James Veitch and Sons in 1859. The plant is quite hardy in this country, but when young is somewhat apt to die off suddenly. Once established, however, it appears to do well, in proof of which I may mention that during my last visit to the Coombe Wood Nursery one of the most striking features was the original plant of this Eucryphia some 15 feet or so in height, bearing hundreds of flowers. Mr. Bean recommends that when young it should be planted

in moist, peaty soil associated with Heaths, so that its roots are shaded. This species is, as a rule, sub-evergreen in character, but there is another one—E. cordifolia—which is strictly evergreen. This has leaves simply heart-shaped, and is more tender than the preceding, though it does well in the warmer districts. E. cordifolia is a native of Valdivia and the Island of Chiloe, where it is said to attain a height of 30 feet or more. Cut sprays of both these species, laden with blossoms, were shown at a recent meeting of the Royal Horticultural Society. *W. T.*

OLD MULBERRY TREE AT BISHOP'S HALL.

AFTER reading Mr. A. D. Webster's article on the Mulberry tree in Muswell Park, London, in the *Gardeners' Chronicle* of August 3 (see p. 41), Lord Lambourne asked me to measure the old Mulberry tree in his garden at Bishop's Hall, Romford, Essex. I did so, and find the diameter of branch spread is 50 feet, and the girth of the trunk 9 feet 6 inches at 3 feet from the ground. *H. Lawrence, The Cottage, Hodge.*

THE ROSARY.

ROSES OF RECENT INTRODUCTION.

At the present period the Roses that are most widely cultivated, on account of their reliable hardiness, and distinctive colouring, are the Wichuraiana and Austrian hybrids, and the Hybrid Teas. Out of all proportion to the diminution of the Noisette and Tea Roses has been the steady increase of highly effective Hybrid Teas, many of these, such as Gorgeous and Mrs. Hugh Dickson, with Summer Austrian Briar climbers, on their own roots, and especially those of the charming "decorative" type. For these beautiful novelties we are indebted to several of the most distinguished of European rosarians, including M. G. Prince, M. Perrot-Dudier, of Lyons (raiser of Madame Edouard Herriot, Rayon d'Or, Constance, Totote Gely, Mlle. Cécile Martel, Raymond, Admiral Ward, and the exquisite tinted Lyon Rose), and to Messrs. Wilson Pearl and Sons, of Waltham Cross, who in recent years have given us Juliet, Prima Donna (the latter the darkest of all Roses of this character), and Aviator. Nor can we forget the great achievements, especially within the last decade, of Messrs. Alex. Dickson and Sons, of Newtownards, from whose nurseries we have received Margaret Dickson Hamill (a distinct acquisition, of radiant colour), Irish Fireflame, and Mrs. Wemyss Quin; of Mr. Hugh Dickson, the redoubtable rosarian of Belfast; or of Mr. Samuel McGredy, of Portadown, in Armagh, the eminent raiser of Mrs. Hugh Dickson, Golden Spray, Flame of Fire, and Golden Emblem Roses, which, by reason of their distinctive character and artistic capabilities, have already achieved a great reputation. Other British rosarians who have contributed to the attractiveness of decorative Roses are Messrs. Benjamin R. Cant and Sons, of Colchester; Mr. George Paul, of Cheshunt, whose Lemon Pillar is a near approximation to the formation of a perfect Rose; Mr. Walter Easlea; and Mr. E. G. Hicks, of Hurst, in Berkshire, whose Princess Mary has (like the even more lustrous Red Letter Day) a beautiful, dark velvet texture, like the flash of a bird's wing in the radiance of the sun.

It is gratifying to remember that many of those modern representatives of the "queen of flowers" are, comparatively, of easy culture, only requiring a sunny, half-sheltered situation (such as I have here at Kirk House, in Wigtownshire), and a rich, fibrous soil. These new Roses have also for the most part the essential attribute of fragrance. What is now chiefly to be desired is a Hybrid Tea, as fascinating in aspect as the dark-hued George Dickson, without its pendulous tendency, or a Golden Emblem, as strong in its growth, and as floriferous in its nature as Bouquet d'Or. Perhaps the nearest approximations to such almost ideally vigorous development and floral capability are the French Constance and the Irish Mrs. Wemyss Quin, which may be reckoned among the finest of all recently introduced, bright yellow Roses. I hope that Christine, which has not yet "ripened," and Golden Emblem, which is not yet established, may prove, eventually, equally vigorous and effective acquisitions. *David R. Williamson.*

FIG. 53.—ECHEVERIA PULVINATA WITH DOUBLE FLOWERS. (See p. 88.)

ON INCREASED FOOD PRODUCTION.

HARVESTING ONIONS.

ONIONS which were sown early in spring now have their top growths bent over, and their bulbs hard and dry. All such should be drawn from the soil at once, but they should not be taken under cover yet. I have known some growers allow Onions to lie on the ground where they were grown, but I think the bulbs do not dry quite so well or quickly under such conditions as when laid on a gravel walk. They should be spread out in a single layer. After remaining thus for two days they should be turned, and this operation must be repeated until the bulbs are firm and dry. The bulbs which are the smallest in the neck at lifting time will dry first, and if really good winter-keeping Onions are needed it is well to select the smallest necked bulbs and dry and store them by themselves. Bulbs with very thick, green, sappy necks should have a goodly part of the top cut off right away, and the remainder twisted to press out the sap.

A few weeks before the Onions are to be lifted it is a good plan to examine the beds and bend down all the thick stems. This retards growth and assists ripening.

A dry day should be chosen for removing the Onions from the ground, and it is better to have them far into September than to harvest them while wet. When suitable weather fails the best way of dealing with them is to take them into some open shed or loft and dry them there. They are improved by being exposed to the sun, if only for a few

days, and the ripening may be finished in sheds afterwards. In any case, they ought to be well dried before being placed in their winter quarters, and the larger the bulbs the more drying they require. I presume others besides myself have noticed that the flavour of Onions in winter is influenced greatly by the way they are harvested. If not properly dried, and afterwards stored in heaps, they lose much of their flavour.

As a rule, I allow my Onion bulbs to remain in the open from ten to fourteen days after lifting, and if the weather is dry at the end of that time they are placed indoors at once.

The place in which to store Onions generally depends on the accommodation provided. Any shed, whether well lighted or nearly dark, is suitable for storing Onions, provided that it is dry and cool. Frost or a high temperature will soon cause decay, and heat does more harm than cold. In winter the Onions here are given much the same treatment as Apples and Pears, and they keep well until Onions are plentiful again in the open quarters. *James A. Paice, Aldenham Vicarage Gardens, Watford.*

EARLY POTATOS.

I was glad to see in Mr. Cuthbertson's remarks on p. 75, that he included as excellent at least two of the varieties I recommended on p. 23. Snowdrop I have found to be second to none for flavour and cooking qualities on our light soil; it is also a satisfactory cropper and a handsome Potato. The crop was about 8 tons per acre, and there is no trace of disease. Epicure has proved an exceptional variety this season in point of earliness, and I estimate the crop at about 12 tons to the acre. I would only commend this sort as an early variety because the tubers have deepset eyes, and would be wasteful if peeled.

King George is reported as the coming second early variety for infected soil, or any soil, and I have found it a first-rate cooker. It is a white, oval tuber, of good size, and a prodigious cropper; in fact, the best cropper we have yet lifted. It is, moreover, a free, vigorous grower, and as yet (third season) we have found no trace of disease.

The old Early Rose turned out excellently, and gave a very heavy crop; this Potato would prove a paying variety to grow, especially on allotments.

The best manure for Potatos is a heavy dressing of farmyard dung. I do not think artificials did a great deal of good this season to early varieties, as those we dressed were no better than those that only had the farmyard manure applied. No doubt the dry weather of spring was responsible for this, and it was also the principal cause of a short crop among many early varieties.

Maincrop and late varieties look well if we except King Edward, which up to this season was the strongest grower and cropper in this neighbourhood. Arran Chief is the strongest grower hereabouts, with Up-to-Date next. *W. A. Cook, Abbots Wood, Godalming.*

PLANT NOTES.

TRICHINIUM MANGLESII AND HEERIA ELEGANS.

I made the experiment of leaving both these plants, which come from the Swan River and Mexico respectively, out last winter. They were covered with dry leaves, and survived 26° of frost. The Trichinium had not made any leaves by the end of July, but on lifting the fleshy roots and placing them in moist sand in a Cucumber house, growth soon started. Both plants flower well out-of-doors, but rather late in the season. *William Lawrence, Burford, Dorking.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Mushrooms.—Where Mushrooms are to be grown, horse manure, freed from long straw, should be collected and placed in an open shed where it can be protected from heavy rains. Turn the heap daily to allow excessive steam to escape. Should the manure become dry, a slight sprinkling of water will be necessary to induce fermentation.

Asparagus Beds. Keep the surface of Asparagus beds free from weeds. After rain, give the beds a good soaking of diluted liquid manure, as this will assist in building up the crowns upon which next year's crop depends.

Cauliflowers.—Fewer plants have "bolted" this season than usual, and favourable weather has caused both the autumn and early spring raised batches to develop quickly. The plants sheltered by frames were naturally the first to come into use. Seed should now be sown on a warm border. Place the resulting seedlings under hand lights in cold frames for the winter; 4 inches apart each way will be sufficient space for them. All gardeners are anxious to have Cauliflowers ready in spring, as soon as the Broccoli is over. Another sowing should be made ten days hence, as this sowing will prove most useful. Eclipse and Walcheren are two old varieties that can be relied upon, with Veitch's Autumn Giant to follow them. Sturdy plants are obtained by sowing thinly and broadcast on moist or newly moistened fine soil. Where birds are troublesome the beds must be netted. Frequent dustings of soot and lime applied when the seedlings are damp will generally act as a deterrent to birds and keep slugs away.

Cucumbers. Make another sowing of seeds to provide plants for fruiting in the winter and early spring months. As these will have to keep up the supply for a long period, they must not be cobbled. Plants will grow very fast during September, but to ensure strong and healthy growth cleanliness and liberal ventilation are necessary. The best compost consists of rough turf, lime rubble, and burnt refuse, with a little soot and bone meal, and as the stems of Cucumbers may be earthed up to almost any extent, the compost need not be more than 9 inches deep to start with. Old plants may be improved by severe pruning, followed by a top-dressing of fresh turf and bone meal, by applications of warm, diluted liquid manure and by copious syringings.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Sophronitis grandiflora. — This brightly-flowered Orchid is now developing new growths, and any plants that require repotting should be given attention. Ordinary shallow Orchid pans form the most suitable receptacles. These should be filled to three-parts their depth with small, clean crocks for drainage. A mixture of equal parts of Osmunda-fibre or A1 fibre and Sphagnum-moss cut up rather short, with a few crushed crocks added, is a suitable rooting medium. Pot the plants moderately firmly, give a surfacing of clean Sphagnum-moss, and suspend in an airy position in the cool Odontoglossum house. During the growing and rooting season, sufficient water should be afforded to keep the surface moss in a healthy condition, and when the plants are dormant they should not be allowed to become sufficiently dry at the roots to cause the pseudo-bulbs to shrive.

Sophro-Cattleya and Sophro-Laelia.—These Orchids are beginning to make new roots, and any necessary repotting should be attended to; the rooting material should contain less Sphagnum-moss than is recommended for the species. The small kinds are best grown in shallow pans and suspended from the roof, while those of larger growth may be cultivated in well-drained pots on the stage, keeping them well exposed to the light. These Orchids do well in an airy position in the intermediate house.

Catesetum, Mormodes, and Cycnoches.—Plants of these genera which have bloomed or completed their growth should be removed from the warmest house to a cooler one that is freely ventilated during the hottest part of the day. The roots should be supplied with water whilst the foliage remains green, but after the leaves have fallen, and the growth is fully matured, very little water will be needed, and the plants should be given a long season of rest in a dry, sunny position in an intermediate temperature.

Cypripedium. Cypripedium insigne and many of its varieties and hybrids are now in full growth. These plants should be freely supplied with water at the roots, and on bright days should be syringed overhead. As much fresh air as possible should be admitted to them during the day, whilst on warm nights both the top and bottom ventilators may be opened.

Pleione. The various Pleiones are completing their growth, and should be increasingly exposed to the light. They should be allowed more liberal ventilation than heretofore. They will need just sufficient water at the roots to keep the compost moist until the foliage falls and until the flower buds appear, when the supply should be increased until the blooms are fully developed. After the flowers have faded the plants should be given only enough water to keep the pseudo-bulbs from shrivelling, until they recommence to grow in the spring. Cooler-growing species, such as P. Hookeriana and P. humilis, will require liberal supplies of water at the roots until the season's growth is completed.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to Mrs. DEMPSTER, Keele Hall, Newcastle, Staffordshire

Renovating Early Vine Borders. The renovation of Vine borders should be carried out immediately after the Grapes are cut. Exhaustion of the borders, and consequent unsatisfactory results in cropping and imperfectly coloured fruit, can generally be traced to a sour and waterlogged condition of the soil. Prepare in advance, under an open shed, a compost of fibrous turf, mixed with mortar or lime rubble, charcoal, or wood ashes, crushed bones, and a light sprinkling of Vine manure. Let the compost be turned several times so as thoroughly to mix the ingredients, and make it into a heap in a moderately moist condition a few days before use. Fork out the soil of the old borders, commencing at the front, and gradually work to within 4 feet o fthe Vines, removing the old soil down to the drainage. Every portion of root should be carefully preserved and syringed occasionally while the work is in progress, then covered with damp mats, for on no account must the roots become dry from exposure. If necessary, let the drainage be overhauled and covered with fresh turves placed grass side downwards. The roughest of the compost should then follow in layers. Make it quite firm, continuing the operation until the border is high enough to receive the first layer of roots. These may be trimmed or shortened where necessary, placed in layers, and covered with the finest part of the compost. It is advisable to bring the roots as near to the surface as possible. When all is completed give the border sufficient tepid water to settle the soil, then cover the surface with light stable litter to conserve the moisture. During bright weather, shade the Vines for a week or so, and syringe frequently, so as to maintain a moist atmosphere until the roots are established. Never place pot plants on newly-prepared vine borders.

General Remarks.—The renovation of fruit borders, the planting of young trees, and the general examination of fruit trees in pots during

the next few weeks makes it necessary to have a general stock-taking in the compost yard. Good, rich, maiden loam should be the first consideration, and if the stock is low, the cutting and carting should be hastened, as it is not advisable to use the turf for some little time after it has been cut and stacked. The work of cutting the turf is most easily performed after a shower of rain but if soil is required immediately, and the weather be dry, then the ground should first be moistened. Other very necessary ingredients consist of mortar or lime rubble, soot, wood ashes, and charcoal. These materials should always be kept under an open shed in tubs or boxes, or in suitably erected compartments, if large quantities are required. Manure must be kept dry, and should therefore be under cover. Give cow manure a slight sprinkling of soot before it is stacked for, apart from its stimulating properties, soot will keep the manure free from worms.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lieut.-Colonel WANTAGE, Lockinge Park, Berkshire.

Azalea.—Ghent and mollis Azaleas are now forming their flower buds, and during this stage their roots must be supplied with diluted liquid farmyard manure and soot water, given alternately. Thoroughly syringe with clear water late in the afternoon of a sultry day.

Hippeastrum (Amaryllis).—The majority of batches of Hippeastrum bulbs should be finished their growth. Place them on a shelf near the roof glass in a position exposed to the sun. Water must now be given sparingly, occasionally allowing the roots to become quite dry. Admit plenty of air to the house, and keep the atmosphere quite cool. Later plants which have not completed their growth should be given plenty of water until the foliage begins to turn yellow, then the supply must be reduced.

Perpetual-Flowering Carnations.—Cuttings which have been outdoors [illegible] should now be placed in a light, airy house. The plants are fairly well rooted but care is necessary not to give them stimulants until the plants commence to flower, as the [illegible] watering with weak soot water will be beneficial. Tie the shoots regularly and use green Bamboo tips as supports. If green fly is present dip the foliage and stems in an insecticide, afterwards fumigating the house as a precaution. Plants which have been outdoors should be syringed with a weak copper sulphate solution at fortnightly intervals as a precaution against attacks of rust. The house should be ventilated freely at all times.

The Plant Stove.—Expose Codiæums (Crotons) fully to the sun in order to obtain good colour in the leaves. Keep the atmosphere moist during spells of hot weather by frequently damping the paths and other bare surfaces during the early part of the day, but let the atmosphere become dry by the evening, as it is only in this way that the heat can be dispersed. During the next few weeks all tropical plants should be somewhat hardened off in readiness for the winter. It is obvious that the temperature of all plant houses will have to be kept much below normal in view of the fuel restrictions.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HARRINGTON, Tyringham, Fenny Stratford.

Dahlia.—The beauty of Dahlias is considerably lessened if means are not taken to thin out the shoots, which, in many varieties, grow vigorously at this season and somewhat hide the buds and flowers. It may be necessary, too, to relieve the plants of some main growths, as this is far better than tying all closely together. Remove seed vessels and old faded flowers from single Dahlias; this will increase the beauty of the plants as well as their floriferousness.

Hollyhocks.—Where the spikes are growing too tall for good effect the tips should be removed. Quantities of seeds will now be ready for gathering, and it must be noted that unless gathered as they approach maturity mice may do the harvesting. If the seeds are sown in boxes as soon as gathered, and the seedlings kept growing, fine strong flowering plants will result by spring time. Care however, should be taken that seeds are not harvested from badly diseased specimens, as the seedlings will contract disease if [illegible] seed be worthless.

Gladiolus.—Early-flowering Gladioli will soon be ready for [illegible]. A very large proportion of the seeds are sown in boxes and the seedlings kept growing throughout winter and [illegible] through the warmer months, so treated [illegible] strong enough to flower in their second year.

Foxgloves.—The beauty [illegible] of Foxgloves is notable. [illegible] where the plants are to flower, [illegible] where there is more space they [illegible] seed. Now is the time [illegible] selected plants. The seeds [illegible] prepared beds for future [illegible] sown broadcast where they are intended to flower, but sometimes the seed on the open ground may be for years before [illegible] the number of the [illegible] plants [illegible] transplanted in a formal manner.

THE HARDY FRUIT GARDEN.

By [illegible], Gardener to Gwydyr Uchaf, Llandudno, North Wales.

Wasps and Ripening Fruit.—More injury is [illegible] Supposing [illegible] provide [illegible] [illegible] [illegible]

EDITORIAL NOTICE.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER, *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 59.6°

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, August 29, 10 a.m., Bar. 30.2, temp. 65° Weather: Sunny.

Isle of Wight Bee Disease.

The cause of this serious disease appears, in spite of many investigations, to be unknown. Originally ascribed to a bacterium, Bacillus pestiformis apis, the disease was subsequently attributed to the action of a parasitic protozoon, Nosena apis. Recent studies conducted at Aberdeen University and also in the West of Scotland Agricultural College do not confirm the latter hypothesis, and leave the cause uncertain. The experiments carried out in Scotland lead to the conclusion that this highly infectious disease has been introduced into various parts of Scotland through the agency of bees imported from infected districts of England. Once introduced, a diseased colony becomes, inevitably, a disseminator of the disease. The spread of Isle of Wight disease may take place in many ways. Robber bees plundering hives of which the inmates are diseased and defenceless may carry away honey and infection as well, or the diseased bees may join the robbers and infect their hives. Further, since even instinct errs, bees may enter strange nests and contract or impart disease, or by sending bees to heather the healthy and the sick may mingle and the latter affect the former.

The West of Scotland experiments* indicate the highly infectious nature of the disease. Thus, by uniting colonies in the last stage of Isle of Wight disease with healthy colonies the malady broke out among the latter in the course of 4-6 weeks. Needless to say, hives in which bees have died from this distemper should be thoroughly disinfected by scraping and washing inside and out with a strong solution of formalin (1 in 60), or, if numbers of hives are to be treated fumigation may be practised by means of lighted formalin candles placed on the floor of the hives.

None of the specifics usually recommended has given Mr. Tinsley successful results, but a new treatment, consisting in the supply to the bees of a pure culture of another bacillus, B. bulgaricus, appears to be promising. This bacillus was prescribed by Metchnikoff as a remedy for intestinal troubles, and hence it seems worth while trying whether it would have any effect on bees affected with Isle of Wight disease, which is known to disturb their digestive apparatus. A culture of Bacillus bulgaricus mixed with syrup, and fed to the diseased bees by means of spraying led to a diminution of the disease, but so far the evidence is not conclusive that a cure may be effected by this means.

The author already referred to believes that the best hope of relief from the disease lies in breeding immune strains. In support of this hope it may be mentioned that strains of bees highly resistant to the disease are known to exist. Experiments are being made with Dutch, Italian, American, and Punic bees. Of native bees those of smaller size appear to be the more resistant. The author believes that as a result of these experiments it may be possible shortly to re-stock districts which have been swept free of bees by the ravages of disease.

* *Preliminary Report on Isle of Wight Bee Disease*, by Joseph Tinsley, Bull. 85, The West of Scotland Agricultural College.

A Seed-Testing Station for Scotland. — It has been officially announced that the Scottish Board of Agriculture has decided to set up a station for the testing and registering of agricultural seeds, and that negotiations are in progress for the leasing of a farm of 200 or 250 acres within easy reach of Edinburgh for the purpose. The present seed testing station of the Board in Edinburgh is to be incorporated in the new scheme, and a manager, with scientific training and practical knowledge of farming, is to be appointed. The superintendent of the station will be an expert with experience of plant breeding and the raising of new varieties, and it is stated that the superintendent of the present seed testing station in Edinburgh is likely to be appointed to this post. The station will be under the control of the Board, and they will be assisted by a representative committee of fifteen, drawn from the Highland and Agricultural Society, the Scottish Chamber of Agriculture, the Scottish National Farmers' Union, the Scottish Seed Trade Association, the Agricultural College, and the National Association of Corn and Agricultural Merchants. The work will comprise the testing of agricultural seeds, with a view to ascertaining the cropping powers of different varieties, of discovering whether new varieties really differ from existing varieties, the determination of synonyms, etc., and of their disease-resisting powers. This station is not to be confused, however, with the proposed research station in connection with plant breeding which it has been suggested should be set up in Scotland.

Eucalyptus.—The thirty-fourth part of Mr. J. H. MAIDEN'S *Critical Revision of the Genus Eucalyptus* treats of the following western species of Eucalyptus, namely: E. redunca, E. accedens, E. cornuta, and E. Websteriana. Each of these offers points of interest. Thus the type form of E. redunca is described as a shoot 3 feet 6 feet high, and it is spread over a considerable area between King George's Sound, Cape Riche, and York. Four other varieties of this species are described, one of which (elata) is a large tree, sometimes reaching a height of 120 feet, with a diameter of 17 feet. The timber is a Jarrah substitute, and some authorities pronounce it to be more durable and even better than Jarrah. It is estimated to occupy 10,000 square miles in the south-west region, from Albany to Murchison River. This variety of E. redunca is said to be the only one of economic importance. It seems odd that the type of a species should rank lower than its varieties. E. cornuta and other species of this group are remarkable for the long, horn-like operculum of their flowers. E. Websteriana is a newly-described, shrubby species, having small, thick, ovate leaves, and otherwise very distinct in its characteristics.

Vegetable Seeds for British Prisoners of War in Germany. — In March last, Messrs. KELWAY AND SON sent a parcel of vegetable seeds for each of the Prisoners' of War Camps in Germany. These were received and forwarded by the Central Prisoners' of War Committee, and Messrs. KELWAY have now received from the Committee a letter of thanks, and also the grateful thanks of the men who have sown the seeds and cultivated the resulting crops in the camps at Altdamm, Dulmen, Friedrichsfeld, Gardelegen, Geissen, Gustrow, Langensalz, Lechfeld, Minden, Munster, and Stendal. Raising vegetable crops from seeds relieves the monotony of existence, and also adds to the amenities of camp life at home, therefore it must be immeasurably interesting and useful in prisoners' camps in an enemy country.

War Item. The latest list of casualties includes the name of Private H. HOLTON, son of Mr. R. H. HOLTON, foreman at Messrs. J. CHEAL AND SONS' nursery, Crawley, Sussex, to whom the deepest sympathy will be extended by his numerous friends in the horticultural world.

The Acacias of Tropical Queensland. — In continuation of his studies of the Acacias of tropical Australia, Mr. J. H. MAIDEN contributes a synopsis of the known Queensland species to the *Proceedings of the Royal Society of Queensland*, Vol. XXX., pp. 18-51, with seven plates. The author has had the advantage of figuring a number of old types preserved at Kew and the British Museum, thus enabling him to clear up many obscure and doubtful points. Sixty-two species are recorded, including four new ones, and they represent practically all the sections of the genus Acacia. No attempt has been made at citing aboriginal or popular names.

The Destruction of Rats. — The abridged account* of Mr. R. SHARPE'S article on "Rats: How to Exterminate Them," contains a large volume of valuable information on a subject which is of great importance at the present time. Mr. SHARPE insists that where poison is used for the destruction of rats it must be used in all parts of the infested ground on the same day otherwise success is not likely to be attained. It is as though the rats, when only part of the area is treated, got to know that something was wrong, and took the precaution of abstaining from doubtful food. Mr. SHARPE recommends SANFORD'S rat poison as being superior to arsenic or strychnine, and harmless to cats and dogs, because they do not touch it, but care must be taken in laying it so that it is out of reach of fowls, pheasants or partridges. The method practised by the author is to collect a supply of small pebbles and to plaster on them one by one, by means of a broad-bladed knife, a pellet of poison about as big as a small Hazel Nut. The pebble is rolled well down the first rat-hole, so as to be out of the reach of thrushes or other birds, and so on with each hole. Mr. SHARPE suggests that the authorities should fix especial rat-poisoning days and insist on the one day treatment of each place infested with these vermin. It is of no use to lay the poison in the same area more often than twice in a year, unless in the case of an area which has been invaded after having been totally cleared. In order to destroy the survivors, some of which are sure to remain after poison day, trapping should be practised. It should be begun three or four days after the laying of the poison. The traps should be laid in the main runs, and not elsewhere. They should be placed lengthwise but somewhat obliquely to the run.

* *Journ. of Bd. of Agric.*, XXIV., No. 12, March, 1918.

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables in *Gardeners' Chronicle* for August 3, p. 42.)

(*Continued from p.* 83.)

3. ENGLAND, E.

Hertfordshire.—The fruit crops in this district are most disappointing. Pears are the worst failure; there were no flowers on any of the Pear trees. There was an abundance of Plum and Apple blossom. Plums flowered a fortnight earlier than usual, but the snow and cold winds of April prevented the blossom from setting fruits. Apples flowered later; the trees were a picture when in bloom and the weather was not unfavourable to pollination, but the trusses of flowers were attacked by aphis. Strawberries have done exceedingly well, and so have other small fruits.—*Walter Fulford, Dellow House Gardens, Abbenhall.*

——There was a good display of bloom on Plum and Cherry trees, but the excessive amount of rain and dull, cheerless weather during the greater part of April destroyed all prospects of a crop. Apple trees in a few sheltered positions are bearing light crops, but many trees are bare, and the Apple crop is one of the lightest we have had for many years. Raspberries and Red Currants were good, but other small fruits were not above the average.—*Thomas Norton, Cheldwellbury Gardens, St. Albans.*

There was very little Pear bloom this season and there is a light crop of fruit. Apples flowered well, but the blossom seemed to be poor, and there is a very light crop. Plum trees flowered profusely and produced a heavy crop, but the fruits failed to swell. Small fruits were good, but the severe drought adversely affected them. Peaches and Nectarines set well and have swelled satisfactorily. Apricot trees set a very heavy crop and the fruits had to be thinned freely. Our soil is a very heavy overlying the London Clay.—*[illegible] Hill, North Mymms Gardens, Hatfield.*

Leicestershire.—[illegible] crop of apples [illegible] Orchards. Apples are a moderate crop, but are not matured, but Pears and Plums are almost entirely absent. Pear trees are bearing an average crop, the trees are clean and making good growth. Small fruits suffered from the continuous drought of June. Raspberries, Strawberries, and Black Currants were the most affected. The soil is of a fairly heavy nature, on a subsoil chiefly of red clay.—*H. Roberts, Prestwold Gardens, Loughborough.*

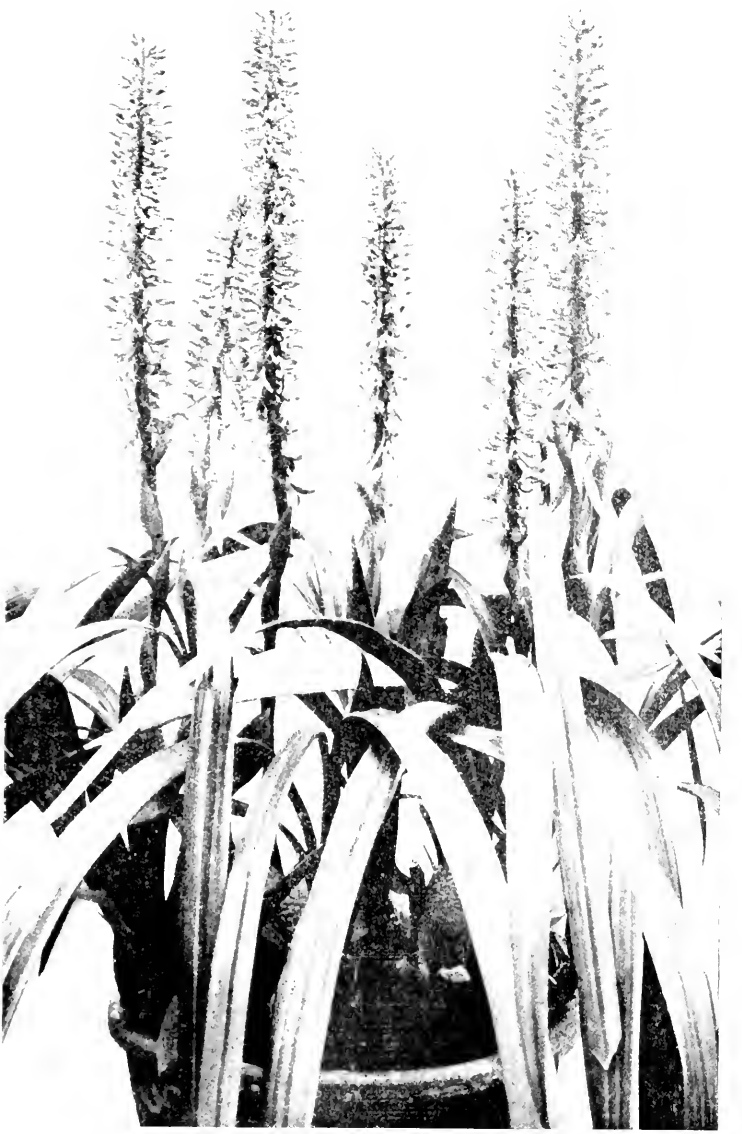
Seldom has there been such a promise of abundant supplies of fruits as this season. Apples, Pears, Peaches and Plums were a mass of bloom, and there was almost an entire absence of frost; but a long succession of cold, moist, genial nights destroyed the blossom. Apple and Pear trees are bearing very thin crops. Wall Peaches, which did well last year, are leafless, while a fair crop of Plums has set on some standards in the open wall trees lost most of their fruit directly it had set. There was a fair crop of Strawberries and bush fruits in the district, but the fruits were of small size owing to a long spell of drought. Our soil is a stiff clay.—*J. Shallcross, Burrough Hill Gardens, Melton Mowbray.*

There is an average crop on some Apple trees, but practically no Pears or Plums. Raspberries are plentiful and very good. The same remark applies to Black and Red Currants and to Gooseberries. The continued drought since May has prevented the small fruits from becoming fully matured, otherwise the crops would have been good.—*W. Paterson, Swithland Hall Gardens, Loughborough.*

Northamptonshire.—The fruit crops generally are very light and of poor quality, but Apricots and Plums on warm walls are yielding fairly well. Gooseberries bore a good crop, but drought and cold nights adversely affected other small fruits, especially Strawberries. Standard Apples and Plums are a failure. Insect pests have been very troublesome. The soil is light loam, overlying ironstone.—*John Meager, Harrowden Hall Gardens, Wellingborough.*

Currants and Strawberries were the best amongst small fruits. Black Currants were a failure.—*S. Barker, Chumbey Park Gardens, Worksop.*

——The hardy fruit crops are, with very few exceptions, under average. The trees generally flowered magnificently, but the good prospects vanished with the advent of the caterpillars,



[Photograph by C. P. Raffill

Fig. 32.—Coptis macrosepala.—flowers rose-coloured.

(See p. 92.)

Nottinghamshire.—Apples, Pears and Plums are very scarce. There was a good show of blossom generally, but it had a weak and unnatural appearance, and did not set well. Although there was a partial set on certain varieties of Apples, a severe attack of caterpillars completed the failure of the Apple crop. Raspberries, Red Currants and Strawberries were the best amongst small fruits. Black Currants were a failure.—*S. Barker, Clumber Park Gardens, Worksop.*

——The hardy fruit crops are, with very few exceptions, under average. The trees generally flowered magnificently, but the good prospects vanished with the advent of the caterpillars, which destroyed whole plantations in some neighbourhoods.—*Arthur C. Ashmore, Peel Hall Gardens, Mansfield Woodhouse.*

The Apple crop this season is uneven, and many varieties are barren. Those carrying good crops are Ribston Pippin, Worcester Pearmain, Lady Sudeley, Mr. Gladstone, Bramley's

Seedling, The Queen, and Newton Wonder. A severe attack of caterpillars when the fruit was setting did much damage to the leaves and fruit. The trees were abundantly laden with blossom, but a general weakness was noticeable in the stamens, and to this I attribute the poor crop more than to the ravages of caterpillars. *James Gibson, Walled Abbey Gardens, Worksop.*

The fruit crop is a disastrous failure in this district. There was a good show of blossom, but a windless weather, followed by a plague of caterpillars, destroyed nearly every thing. *J. R. Pearson and Sons, Lowdham.*

Apple trees bloomed very well, but after a long, dull spell the weather became suddenly very warm, and seemed to scorch the bloom. Worcester Pearmain, Cox's Orange Pippin, King of the Pippins, Edinville Seedling, Warner's King, and Lord Suffield are the best varieties with us. Pears are very scarce in this district. Cold, east winds prevailed when the trees were in flower. Raspberries yielded a fine crop in spite of want of rain. *Thomas Simpson, Newstead Abbey Gardens, Lynby.*

(*To be continued.*)

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

American Blight. With me this pest is much more plentiful than I have ever seen it. Why, I am at a loss to understand. Even the Crab trees in the hedges are smothered with the insects, but how they got there I cannot understand. As to varieties of Apples that are the more susceptible to the pest, there is not much to choose. Warner's King has always been the most seriously affected sort here. Cox's Orange Pippin and Worcester Pearmain follow closely. While wounds on the main branches from canker are the favourite hiding places of the insects, the young shoots are not immune. I have used many so-called remedies including methylated spirits and tar, but none is so effective as Bunyard's Blight Cure, which is easily applied to the affected parts with a stiff brush. *J. Molyneux, Swanmore Park Farm, Bishop's Waltham.*

Fruiting of Chimonanthus fragrans (see p. 83). The production of a fruit of the "Wax Tree Sweet" at a recent meeting of the Scientific Committee of the Royal Horticultural Society would suggest that the fruiting of this shrub in England is rare. This is not the case. In Surrey, at Fox Oak, Walton-on-Thames, for three consecutive seasons, I saw a wall shrub and also a shrubbery specimen both fruiting freely, and the gardener, who has been there for many years, told me that it was quite usual to have a good crop of fruits. I sowed nine seeds and seven germinated, growing into healthy plants very quickly. In *Trees and Shrubs*, an abridgement of *Arboretum et Fruticetum Britannicum*, London states: "The plant is generally propagated by layers, but it frequently produces seeds, from which many plants have been raised." *H. C. Burbidge.*

SOCIETIES.

ROYAL HORTICULTURAL.

August 27.—Although the attendance was very small at the meeting held in the Drill Hall, Westminster, on Tuesday last, the exhibition was a creditable one for late August. The Joint Dahlia Committee, consisting of members of the R.H.S. Floral Committee and the National Dahlia Society, made nine awards to novelties. The Floral Committee recommended six Awards of Merit and awarded eight medals, including a Gold Medal for a splendid display of Montbretias.

The Fruit and Vegetable Committee awarded one medal to a collection of fruits. The Orchid Committee granted one First-class Certificate and two Awards of Merit to novelties, and awarded three medals to groups.

Floral Committee.

Present: Messrs. H. B. May (in the chair), R. C. Notcutt, Sydney Morris, John Green, E. A. Bowles, G. Reuthe, John Heal, C. R. Fielder, J. F. McLeod, A. Turner, W. H. Page, Thos. Stevenson, H. J. Jones, J. W. Moorman, Chas. Dixon, John Dickson, E. F. Hazelton, W. P. Thomson, Chas. E. Pearson, R. W. Wallace and E. H. Jenkins.

AWARDS OF MERIT.

Montbretia Queen Mary (see fig. 33).—This glorious variety grows about a yard high and bears many-branched spikes upon which numerous flowers remain open at the same time. The individual blooms are about 2 inches across, coloured light orange-yellow, with deeper orange reverse, and small crimson marks at the mouth of the tube. The stems are dark and stout.

FIG. 33.—MONTBRETIA QUEEN MARY.
(See Awards by the Floral Committee.)

Montbretia Nimbus.—This variety is of more upright habit than most, the side branches growing more erect than usual. The colour of the flowers is deep gold, with a ring of soft red-brown towards the base of the segments, and a few small markings of the same colour at the

mouth of the tube; a very free-flowering and effective variety.

Montbretia Queen Alexandra.—An erect, slender-stemmed variety which bears moderate-sized flowers that are of unusually good, rounded form. The colour is light apricot-yellow, with purplish-red markings at the bases of the lower three segments; a very elegant variety. This and the two following varieties were raised and shown by SYDNEY MORRIS, Esq. (gr. Mr. S. Henley), Earlham Hall, Norwich.

Gladiolus Prophetess.—A dainty variety with shapely flowers and good spikes. The blooms are cream white, with large red-brown blotches on the bases of the three lower segments. In form and texture the flowers are first-rate. Shown by Mr. J. S. PARKER, Upton Cheyney, Bitton.

Lilium Parkmanii Hayward's var.—A handsome form of a fine Lily. It was exhibited as the result of crossing L. speciosum magnificum with L. auratum macranthum. In general appearance it is like a glorified L. speciosum with the segments flattened out instead of being recurved. The colour is deep pink, with whitish margins and red-brown spots. One spike shown had a fasciated stem and carried a large number of blooms, but these were not so fine as those on an ordinary inflorescence. The flowers are very fragrant, with the scent of L. auratum but not so strong. Shown by Mr. P. S. HAYWARD, Pearls Farm, Great Clacton.

Lobelia Mrs. Humbert.—A useful, free-flowering hardy herbaceous Lobelia, with stems a yard high bearing a 15-inch spike of clear pink flowers. Shown by Messrs. LADHAMS.

MEDALS

Gold.—To S. MORRIS, Esq., Earlham Hall, Norwich, for Montbretias. *Silver-gilt Banksian.*—To Mr. L. R. RUSSELL, for stove plants. *Silver Flora.*—To Messrs. H. B. MAY AND SONS, for Ferns and Bouvardias. *Silver Banksian.*—To Messrs. CHEAL AND SONS, for Dahlias and shrubs; Messrs. LADHAMS, for herbaceous Lobelias and other hardy flowers; Rev. J. H. PEMBERTON, for Roses; Mr. G. REUTHE, for hardy plants; and to Mr. W. WELLS, June, for Delphiniums in great variety.

DAHLIAS.

The Joint Committee of the R.H.S. and the National Dahlia Society was as follows: Messrs. H. B. May (in the chair), J. Cheal, J. Green, J. A. Jarrett, D. B. Crane, H. J. Jones, Arthur Turner, C. H. Curtis, E. M. Jenkins, J. F. McLeod, and S. Mortimer.

The following Dahlias received the R.H.S. Award of Merit and the N.D.S. First-class Certificate:—

Marion Walton.—A charming garden Cactus Dahlia of great decorative value. The stems are long and stiff; the flowers of fair size, are coloured rich rose-pink, with buff shading at the bases of the central segments.

Purple Emperor.—A very handsome and distinct decorative variety. The flowers are of large size and carried boldly on stout stems. The segments are broad and the blooms regular in outline. The colour is deep purple tinted maroon with bright purple reverse, the latter colour showing up in the short, central segments.

Pennant.—This handsome Cactus variety has large blooms composed of slender incurving segments that produce an elegant effect. The colour is rich salmon-rose, a distinct shade.

Meridian.—A large Cactus Dahlia of fine form with graceful, slender-pointed segments and a neat centre. The colour is pale straw-yellow. Stems long and stiff.

These four varieties were shown by Messrs. J. STEVENSON AND SON.

President Wilson.—A huge and gorgeous decorative Dahlia of splendid form and with very long, stout stems that carry the flowers erect. The broad segments have their edges somewhat reflexed towards the ends, thus producing a pointed effect that adds to the fine appearance of the bloom. Shown by Mr. J. T. WEST.

Southern Star.—This is another addition to the "Star" group of Dahlias. This group consists of very useful varieties, particularly suitable for garden decoration and for supplying cut blooms. The variety has the same elegant form as its congeners, but the colour is scarlet, streaked with yellow, and shading into pink at the tips of the segments. Shown by Messrs. J. CHEAL AND SONS.

Pink Apollo.—A long-stemmed Paeony-flowered Dahlia. The blooms have two, sometimes three, rows of broad segments, and are over 6 inches across. The colour is clear pink.

Star of Stars.—A bold Collerette Dahlia. The flowers are of fairly good form and size, and carried on stiff stems. The broad segments are deep rosy-scarlet, tipped with pale yellow; the prominent "collar" is pale yellow with red shading.

Evelyn.—A showy Coloniette variety, with broad, slightly reflexing segments. The colour is maroon-scarlet, paler at the tips. The "collar" is composed of very narrow, pale yellow segments, those at inch long.

These three varieties were raised and shown by Mr. J. A. JARRETT, Anerley.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Sir Harry J. Veitch, Messrs. Jas. O'Brien (hon. secretary), C. J. Lucas, W. H. White, W. Bolton, Walter Cobb, J. E. Shill, J. Charlesworth, Fred. Sander, W. J. Kaye, Richard G. Thwaites, J. Wilson Potter, Chas. H. Curtis, S. W. Flory and R. A. Rolfe.

AWARDS.

FIRST-CLASS CERTIFICATE.

Cattleya Hardyana alba, var. President Wilson, from Messrs. FLORY AND BLACK, Slough.—A magnificent variety resulting from crossing C. Dowiana aurea and a white-petalled C. Warscewiczii. The large, broadly developed flowers have pure white sepals and petals and glowing ruby purple lip with gold lines from the base to the centre, where, on each side are patches of light chrome-yellow.

AWARDS OF MERIT.

Cattleya Iris Andoldus variety (bicolor × Dowiana aurea), from J. ANSAULDO, Esq., Rosebank, Mumbles. A large, handsome variety, differing from others in having more of C. Dowiana aurea in the constitution, and in consequence a broader isthmus of the lip. The broad sepals and petals are pale sap-green, changing to primrose-yellow, and with faint, purplish veining. The lip is deep purplish-crimson with gold markings in the median area; column white.

Cattleya Ignea, Prince of Denmark (Dowiana aurea), from Messrs. CHARLESWORTH AND CO., Haywards Heath.—The flowers are formed like those of C. Dowiana, but with shorter petals. The sepals and petals are bright yellow, the lip ruby-crimson with gold veining from the base to the centre.

CERTIFICATE OF APPRECIATION.

Odontoglossum Ingall-Skinnerii × crinnium, from C. J. LUCAS, Esq., Warnham Court, Horsham (gr. Mr. Duncan). A new hybrid with well-formed flowers of medium size and showing O. Uro-Skinneri in a marked degree in the labellum. The sepals and petals are heavily barred with purple, the white ground showing through in narrow, wavy lines. The lip is white with purple blotches around the yellow crest and a band of small rose-coloured spots inside the margin in front.

GROUPS.

Messrs. STUART LOW AND CO., Jarvis Brook, Sussex, were awarded a Silver-gilt Flora Medal for an extensive and well-arranged group of showy species and hybrids. Cattleya Warscewiczii in several good varieties; Sophro-Cattleya Doris, S.-C. Blenheim and other Sophronitis crosses were effectively displayed with showy Laelio-Cattleyas, the best of which was L.-C. Sargent (L.-C. Lustre × C. Hardyana), a very large and handsome rose flower with broad, ruby-claret lip. New hybrids included Brasso-Cattleya Cuneata (B. Digbyana × C. Mrs. Myra Peeters), a large silver-white flower tinged with rose-colour on the broad, fringed lip being the darker shade.

Messrs. CHARLESWORTH AND CO., Haywards Heath, were awarded a Silver Flora Medal for a group of showy hybrids, including forms of their Laelio-Cattleya Appam, which secured an Award of Merit at the previous meeting; L.-C. Marina varieties with large and finely formed flowers, and several handsome varieties of their strain of Cattleya Serbia, all of good shape and bright colouring.

Messrs. HASSALL AND CO., Southgate, were awarded a Silver Flora Medal for a group of showy hybrids, the novelty in which was Brasso-Laelio-Cattleya Muriel (B.-C. Madame Chas. Maron × L.-C. Feronia), a large, light rose-coloured flower with greenish-yellow disc to the broad, fringed lip. Forms of Cattleya Nardi candidissima × Hardyana), one richly coloured form approaching C. Venus in the glowing crimson and form of its lip, and white-petalled varieties of Cattleya Hardyana were included in the exhibit.

Fruit and Vegetable Committee.

Present: Messrs. Joseph Cheal (in the chair), W. Poupart, Owen Thomas, W. H. Divers, J. C. Allgrove, Edwin Beckett, A. Markham, F. Jordan, A. Bullock, A. W. Metcalfe, E. A. Bunyard, George P. Berry, and the Rev. W. Wilks.

Messrs. S. SPOONER AND SONS exhibited a few dishes and baskets of Apples, the most attractive varieties being Lady Sudeley, Worcester Pearmain, and Williams' Favourite (Silver Knightian Medal).

An attractive Apple, shapely and with crimson streaks and shading on a pale yellow ground, named Maidstone Favourite, was shown by Messrs. G. BUNYARD AND CO.

LIVERPOOL VEGETABLE EXHIBITION.

AUGUST 23 AND 24.—The show held at St. George's Hall, under the auspices of the City Council and the Liverpool Horticultural Association, was a great success. The exhibits were about 2,000 in number, and in many cases the produce was of excellent quality.

The premier award, a Silver Challenge Vase presented by Alderman J. R. Grant, was won by the Walton Allotment Gardens Association, Seeds Lane, Fazakerley, and the ten plot holders who contributed to the collection each received a silver medal.

Two Silver Goblets were offered for the best collection of vegetables from any Association, arranged on a space of 50 square feet; one for allotments cultivated during 1918, in which the Waverley Allotment Association proved the winners, and the other for allotments cultivated prior to 1918, in which the Walton Allotments were successful. Both exhibits had a varied and excellent display of vegetables.

Five Gold Medals were given for individual plots. Those for plots cultivated prior to 1918 were won by Mr. W. SWINDELLS, Seeds Lane North District; Mr. J. H. WALKER, Green Lane Drive (South), and Mr. W. JACKSON, Bowring Park (East). For the plots broken up during the present year, Mr. E. G. MAYLETT, Sefton Park (South) and Mr. W. C. HUMPHRIES, Woolton (East) were the winners.

DUMFRIES AND DISTRICT HORTICULTURAL

AUGUST 24.—This Society held a show of vegetables and a gift sale of vegetables, flowers and fruit in St. Mary's Hall, Dumfries, on the 24th inst. There was a large attendance at the opening, presided over by Provost S. Arnott, Mrs. Gillespie, chairman of the Society; the show was opened by Sheriff Campion. Prize cups were presented by Provost T. S. Macaulay, Dumfries. The show of vegetables was an excellent one. A bronze medal was awarded to Mr. J. Cromie, June., York Place Nursery, Dumfries, for a collection of Potatos. The gift sale, which was on behalf of war charities, was handsomely supported by contributions from a number of gardens in the district.

In the open class the best collection of vegetables was shown by Mr. R. A. Gricor, Junr., Dalswinton Gardens.

The challenge cup presented by the proprietors of the "Dumfries and Galloway Standard" for the best collection of vegetables was awarded to Mr. W. KERR, Dalswinton Village.

The show of the Dumfries Burgh Allotment Holders' Association was held in conjunction. The Dumfries Burgh Cup for the champion allotment was won by Mr. J. BUSHEL, Crairs Road Allotments.

CROPS AND STOCK ON THE HOME FARM.

Wheat.

Much Wheat is being threshed owing to a lack of straw for thatching ricks of cereals and second-cut hay, of which much is being made. These second crops of hay are very good, and the weather is favourable for them. Owing to the tardiness of the authorities in fixing the price for Wheat for the current harvest, few sales are taking place; with the increase in wages, manures, and all feeding-stuffs, growers are naturally anxious. In fixing the price of Barley at 67s. per quarter, and Oats at 47s. 6d., the Government has treated farmers quite liberally. Many farmers state that Wheat is not threshing out in such good condition and quality as was expected. From observation of our own and other crops, I think there will be disappointment as to the quality of the grain, especially where the land was not well prepared. What I mean by quality is explained by the word "strength," a term used by millers to indicate that the endosperm of the Wheat should be hard and translucent, resembling horn when cut across. Such Wheat contains "strength," much appreciated by the miller, yielding flour which produces loaves that are large and spongy in texture. In "weak" Wheat the floury part of the grain is white and opaque, and looks like chalk when cut. Grains with such a starchy content are usually soft and not so desirable as the stronger grains.

The cold, sunless weather in April and early part of May no doubt caused many plots to be affected by rust (Puccinia graminis), thus checking the progress of the Wheat plant. The extreme dry weather during the latter half of June and the early part of July checked the filling out of the grain. Although Wheat does not require so much moisture as other grain crops, a sufficiency is needed to swell the grain to its fullest extent. Some samples are termed "hoaty," as the centre of the grain is not filled out. It is difficult to imagine a Wheat crop of the finest quality when the leaves have been ruined by this disease. Large breadths of spring-sown Wheat were cultivated this season, especially on newly-ploughed pu grass land, mainly of the Red Nursery variety. The demand at that time appeared to be more for Wheat than Oats and farmers responded readily to the request to increase the supply of this cereal. In my own case, nine acres of grass were ploughed and sown, on March 6, with Red Nursery Wheat, which has given an excellent crop of high quality. The yield of this Wheat is not equal to that of autumn-sown plots of other varieties, but where a late growth is required this is an excellent variety to sow.

Cleaning Stubbles.

Directly harvest is completed the cleaning of stubbles usually occupies the horses. With the spell of dry weather usually experienced in September a good opportunity is afforded of getting rid of troublesome weeds, which are all too common this season. In many cases this is owing to the extra grass, old Sainfoin leys, and rotation grasses being ploughed. From those latter we always expect a full Couch crop. For tearing up stubbles of this class nothing is so useful as steam tackle for scarifying the land twice in opposite directions. Then with the aid of sun and wind, horse cultivators and harrows, the loll of the weeds and stubble can be gathered, burnt in small heaps, and the ashes spread over the soil.

Sunflowers.

The recent spell of hot weather preceded by the copious rainfall in the middle of July, has been all in favour of rapid growth and the development of the flower heads, which are, in the case of the Giant Russian variety, some 15 inches in diameter, now well set with seed. In my acre plot half was sown with seed and the remainder dibbled with seedlings raised in boxes in a cold frame and planted during the middle of May. Although the former batch has grown more vigorously (now 7 feet high the frame-raised plants are more uniform in growth, and perfecting a full seed crop which should ripen well. *E. Molyneux, Swanmore Park, Bishop's Waltham.*

Vegetable Marrows, per doz	2 0	4 0
Watercress, per doz	0 0	9 1/2

Remarks. The apple continues to be fairly well supplied with Apples, both for cooking and dessert varieties, but supplies of Pears are limited. Plums and Greengages have shown a slight increase in supply this week. Home-grown Melons are now practically at an end, but Canada has a few medium size fruits available. The first shipment of Grapes are expected to hand. Peaches and Nectarines are in short supply this week, but all varieties of Grapes are fairly abundant. Supplies of Tomatos have shown a slight increase, and Mushrooms, Cucumbers, Marrows, and Cabbage are scarce, especially the last. Scarlet Runner beans are plentiful, but Cauliflowers somewhat scarce. Supplies of Peas are limited. *E. H. J., Covent Garden Market, August 28, '18.*

ENQUIRY.

Druidical Plants.

I shall be very grateful if your readers will kindly (1) mention any plants that are associated with Druidical rites or that are known to have been noticed or used by the early Britons, and suitable for planting in this connection, and (2) refer me to any accessible books on plant lore that would deal with the subject. *Welsh Reader.*

Obituary.

Peter Loney.—We regret to announce that Mr. Peter Loney died suddenly at the residence of his son, Dr. Loney, Wrenbury, Cheshire, on the 11th inst. Mr. Loney was head gardener at Marchmont, Berwickshire, the residence of Sir Hugh Hume Campbell, and he was afterwards appointed overseer on Sir Hugh's Marchmont and Hume estates, in which capacity he acted for many years. Over twenty years ago he retired, and took up his residence in Edinburgh. For some years he was honorary secretary of the Scottish Horticultural Association, of which he was an honorary life member. He was in his 85th year.

Andrew Thomson.—We regret to announce the death, on August 21, of Mr. Andrew Thomson, a leading amateur horticulturist of Galashiels, and for many years president of the Galashiels Horticultural Society. Mr. Thomson, who was headmaster of the Galashiels Burgh Schools, was 66 years of age.

ANSWERS TO CORRESPONDENTS.

Barberries: *M. E. H.* The fruits of Berberis Aquifolium are edible, but not particularly palatable. The fruit of the common, wild Berberis vulgaris, are edible, but rather arid. Most of the Barberry fruits make good preserve and are sometimes employed for making into jelly.

Names of Fruits: *Ignorammus.* Plums: 1, Victoria; 2, Belgian Purple; 3, Prince Engelbert; 4, Prince of Wales; 5, Monarch.—*J. E.* Apple, Irish Peach; Pear, Hessel; Plum, Rivers' Early.

Names of Plants: *H. S.* 1, Clethra alnifolia; 2, Koelreuteria paniculata; 3, Arbutus Unedo; 4, Abelia grandiflora; 5 and 6, varieties of Hibiscus syriacus. *G. H. E.* Colquhounia grandiflora. *B. W.* Artemisia vulgaris. *C. D.* 1, Exochorda grandiflora; 2, Rhododendron myrtifolium; 3, Cornus Mas; 4, Holboellia latifolia; 5, Skimmia Laureola; 6, Forsythia viridissima; 7, Cornus capitata (?).—*A. N.* Lycium chinense (see answer under "Wayside Shrub").—*C. G.* 1, Old Monthly Rose; 2, probably Lathyrus amphoricarpus.

Celery Leaves Injured: *S. R.* The leaves are attacked by Celery Leaf Blight, Cercospora apii. Collect and destroy all diseased leaves, and, next season, spray the young plants with a solution of ammoniacal carbonate of copper.

Potatos on Newly Dug Pasture: *Ploughman.* There is no royal road to combatting wireworm in old pasture; an application of gas-lime, when the ground is fallow, is the best means of destroying this pest. Each succeeding season you will have less trouble in this respect, as a proportion of the grubs will hatch into the beetle stage each year, and they rarely return to cultivated ground. With respect to manures, as you are unable to obtain stable dung, dress the ground with superphosphate as soon as it is dug in the spring and apply sulphate of ammonia at the time of planting the seed tubers. If preferred, you can substitute basic slag for the superphosphate, but this fertiliser should be applied in the autumn, as it is very slow in action. Use superphosphate at the rate of 3 ozs. to the square yard, and about half that amount of sulphate of ammonia.

Wayside Shrub: *H.* So far as we are aware, the fruits of the wayside shrub (Lycium chinense, better known as L. barbarum) are not edible. The fruits of many solanaceous plants are poisonous and others are unpalatable, but fruits of a few cultivated kinds are largely used for food, notably Tomatos, Aubergines, Capsicums, Chilies, and Cape Gooseberries.

ANGELICA.

THIS summer the grievance of our war-time food supplies has been aggravated by the general enhancement in price of fresh fruit, whilst the shortage of this season's harvest of Plums, Pears and Apples promises to make matters increasingly difficult until the crops of next season mature. Thus it has fallen to the lot of Rhubarb to fill the gap to such an extent that its higher price and lower quality are much in evidence. The fruit-grower who possesses acres of Rhubarb fields finds himself comparable to the owner of a gold mine. The greengrocers' shops show very plainly how the rapid realisation of the gross profits of present opportunity are somewhat straining the productive capacity of the Rhubarb fields during the coming year by reason of prolonged and excessive gatherings, which are incompatible with the rest period so necessary after midsummer for recovery of growth and preparation for proper crop development next spring.

Whilst Rhubarb, our emergency substitute for bush and tree fruits, is thus being made to supply the wants of the multitude, not a few of us are inclined to revolt and long for some amelioration of this too frequent component of our daily meals. Rhubarb jam and Rhubarb tarts have become odious to many palates even when doctored with ginger, lemon, and common flavouring essences. A blend of Raspberry and Rhubarb has been the most popular standby, but even such a compound is a luxury often not obtainable.

Accordingly the times seem fit for the rehabilitation of the "herb Angelica" in some part of its old-time repute; unfortunately, it is nowadays seldom to be found either in the cottager's garden patch or in the best old manor house gardens; it is quite unknown to the war-time allotment holder. Its best use by us when it may be classed as a food rather than a mere condiment, is woefully neglected or unknown.

Archangelica officinalis (garden Angelica) merely lingers inconspicuously to-day amongst the stock-in-trade of our surviving medicinal herbalists, generally in the form of a dry, powdered root. It is known to modern cooks and confectioners only in the form of crystallised "candied Angelica," prepared from split lengths of the flowering stems cut in the month of May. Botanists and antiquarians have written fully about this deliciously aromatic herb and old-time food plant, but nevertheless its food and condiment value have practically been lost to us following upon its disuse in medicine and its banishment from our kitchen gardens, which occurred a little earlier than 1800, when, however, the second edition of the *Gardeners' Chronicle* still represented the herb as "a well-known plant in most cottage gardens."

The herb Angelica belongs to the Natural Order *Umbelliferæ*. Several of our common wild Umbelliferous plants [illegible] Angelica, which is sometimes found wild, but is only a garden escape. Our wild native plant Angelica sylvestris, [illegible] Hemlock, of Water Dropwort, Cow Parsnip, Cow Chervil, Fool's Parsley, Water Hemlock, or Water Dropwort, Wild Carrot, Hedge Parsley, Sweet Cicely, Sanicle, Alexanders, Lovage, Masterwort, Caraway, Fennel, Parsley, Celery, Hemlock, Spotted Hemlock, Wild Parsnip, Wild Chervil, Sea Holly, Sea Parsley, Samphire, Stone Parsley, Hare's Ear, Milk Parsley, Wild Angelica, Water Hemlock, or

a very sugary confection thereof, somewhat resembles candied Angelica in flavour.

In Courland, Livonia, and the low lakelands of Pomerania and East Prussia wild-growing Angelica abounds; there, in early summer-time, it is the custom of some peasants to march into the towns carrying the Angelica flower-stems and to offer them for sale, chanting some ancient ditty in Letzish words, so antiquated as to be unintelligible to the singers themselves. The chanted words and the tune are learned in childhood, and are to be attributed to a survival of some Pagan festival. The Finns esteem the herb also as a food, as well as otherwise; they eat the young stems baked in hot ashes, and an infusion of the dried leaves is drunk either hot or cold; the flavour of this decoction is rather bitter; the colour is a pale greenish-grey, and the odour greatly resembles China tea. The roots of Angelica are, or were, used medicinally either fresh, or dried and powdered, in which latter form one dram, a little more or less, constitutes a dose.—*G. Harlstone Hardy (Major), Twickenham.*

a dark violet shade, the central part being bright claret-red with some light orange markings. The side lobes of the lip are light rose colour marked with fine purple lines; the fleshy column is white.

The variety King Edward VII., with yellow sepals and petals tinged with rose colour and with a magenta-rose coloured lip, was illustrated in *Gard. Chron.*, October 16, 1909, fig. 114.

CATTLEYA SUNSET

A flower of a new cross between C. Dowiana aurea and C. Tankervilliæ (bicolor × Rex) is sent by C. J. Lucas, Esq., Wareham Court, Horsham (gr. Mr. Duncan), in whose garden it was raised. In the chief features it resembles a very fine C. Iris, but the introduction of C. Rex has produced a broader expansion of the side lobes of the lip which are apricot yellow outside and veined with purple inside—and a fine development of the purplish crimson front lobe, which has a narrow, white, undulated margin. The narrower middle part of the lip is bright yellow, with crimson lines. The sepals and petals are apricot yellow tinged and slightly veined with rose-crimson. The column is white flushed with purple and is very fleshy.

THE MARKET FRUIT GARDEN.

August was a glorious month, with more than the average amount of sunshine and less than the normal rainfall. The opening week was wet, but from the 8th to the 24th inclusive there was an interval without any measurable quantity of rain, the weather being fine and warm. The total fall for the month in my garden was only 1·27 inch, which fell on 9 days, a great contrast to 5·66 inches on 20 days in August, 1917. But the contrast was even more satisfactory in the matter of wind. Last year there were two severe gales in August which brought down hundreds of bushels of Apples and many Plums. All available buildings were filled with windfalls, for which an adequate supply of "empties" could not be obtained. This year there have been remarkably few windfalls, the season's immunity from gales being quite exceptional. The weather has, moreover, been favourable for gathering the crops and for hoeing, and the light crops have necessitated so little time being devoted to the former operation that there has been ample opportunity for keeping down weeds. The plantations are therefore unusually clean for the time of year.

The extraordinary failure of the fruit crops is realised more strikingly in the packing and marketing department than anywhere else. Usually at this season we are accustomed to pack daily at high pressure, and often send three times to the railway station day after day. This year packing has seldom occupied more than two days a week, and the van makes one journey to the station on each occasion. As varieties ripen they are picked and marketed direct, and the fruit-room is empty.

PRUNING BLACK CURRANTS.

So little time being required for picking and packing, there are opportunities for doing work which usually has to be neglected. The pruning of Black Currants is a case in point. Our practice has always been to cut back the bushes for the first two years after planting, but after that they have received no attention from the knife, more urgent pruning work occupying the time of the few skilled men. This year some of the bushes have been dealt with, and they certainly

FIG. 34.—FRUITS OF PYRUS YUNNANENSIS.

ORCHID NOTES AND CLEANINGS.

CATTLEYA IRIS ANSALDO'S VARIETY.

Cattleya Iris, obtained by crossing C. bicolor and C. Dowiana aurea, was first recorded in *The Garden* as *Chron.* 8 September 28, 1901, p. 250. The hybrid proved to be one of the most distinct and popular of Orchids, and good types of it are eagerly sought to-day as they were when it first made its appearance. Considerable variation is seen in size and colour as displayed in different forms of the cross, but hitherto the shape of the lip, with its more or less restricted isthmus in the centre and its short side lobes at the base, has been inherited from C. bicolor.

In the case illustrated in fig. 36, for which J. Ansaldo, Esq., Rosebank, Mumbles, Glamorgan, received an Award of Merit at the meeting of the Royal Horticultural Society on August 27, the influence of C. Dowiana aurea is especially pronounced, with the result that the segments are broader than usual and there is a greater expansion of the labellum. The sepals and petals are pale sap-green, changing to primrose-yellow, with a pale rose flush and veining of light purple. The labellum is deep ruby crimson with

TREES AND SHRUBS.

PYRUS YUNNANENSIS
(syn. P. VEITCHII).

We owe to Mr. E. H. Wilson the introduction to gardens of this interesting and attractive tree. He found it during one of his early journeys in China on behalf of Messrs. J. Veitch and Sons. Its chief beauty is its rich crop of fruits, which are at their best in September. The fruits are a rich, dark red, dotted with pale spots, almost globose, and about half an inch in diameter. The flowers are white, but the spring beauty of the tree is inferior to that of our best flowering Pyruses. It is evidently a very hardy tree, and thrives in good, loamy soil in full sunshine. Messrs. J. Veitch and Sons showed the species a few times at the R.H.S. fortnightly meetings under the provisional name of Pyrus Veitchii, and on October 8, 1912, when it bore a remarkable crop of fruits, it was given an Award of Merit.—*W. J. B.*

look all the better for the attention. Neglected Black Currant bushes are somewhat puzzling subjects to prune. The object is, of course, to cut out old wood and make room for new, but it is often difficult to remove the one without a considerable amount of the other. The work is bound to involve the sacrifice of a portion of next season's crop, but it is hoped that it will produce more young wood for the crops of future years and give the bushes a longer lease of life. Unpruned bushes crop well, but I believe that they wear out prematurely, whilst they grow so tall as to be a nuisance in a mixed plantation of trees and bushes. My chief aim in this pruning has been to cut back some of the old wood to within a few inches of the ground, in the hope of inducing the bushes to throw up some strong, young shoots: they never do this freely on my land, which does not suit the crop.

In some of the plantations the bushes were planted only 3 feet apart in the rows, with the object of cutting down alternate specimens at intervals, and so keeping them perpetually furnished with young wood, and possibly defeating the bud mite. Unfortunately the plan has never been carried through. It has been put off from year to year, because it seemed a pity to cut down bushes that were bearing fully. Last year, however, a few bushes were treated as an experiment, and the result is so favourable that I have now cut down alternate bushes in the greater part of one plantation that is not too old to give the system a fair test. There is no doubt about the success of the plan with regard to the formation of new wood. Plenty of very strong shoots are formed, and the bushes are quite rejuvenated. It remains to be seen, however, whether this wood will remain free from bud mite. I shall not be surprised to see it badly infested, as the pests seem to prefer young shoots. Nor am I at all sure that there will not be a proportion of reverted bushes as a result of the treatment. Some of those cut back last year look suspicious.

DEAD WOOD IN PLUM TREES.

The opportunity is now being taken to prune the older Plum trees. It would be too severe, of course, to deal with young trees, on which the leaders have to be shortened, but older trees require nothing beyond the removal of dead and overcrowded wood, and this can be done at any time of the year. It is, indeed, much easier to distinguish dead wood whilst the leaves are still on the trees. There is a great deal of it, particularly on trees of Czar, as a result of brown rot disease, of which there has been a particularly severe attack this year, here and elsewhere. Silver-leaved branches also should always be cut out early, as they cannot be distinguished when the leaves change colour in autumn. We have already gone through the plantation with this object, marking trees that show silver-leaf all over to be grubbed, and sawing off diseased limbs where the trouble is restricted to part of the tree. This disease also has spread seriously this year. The variety Victoria, as usual, is affected worst, but the trouble is found also in Czar, Pond's Seedling, and a few trees of Monarch.

THE COBNUT CROP.

There is a light crop of Cobnuts, but it is better than was expected. There was a heavy crop last year, and Cobnuts seem to cycle, with many varieties of Apples and Plums, the habit of bearing in alternate years. There was, however, a stronger reason for expecting a very light yield in the scarcity of catkins. Most of the trees carried plenty of female blooms, but the majority were entirely bare of male catkins. At the same time I never remember to have seen catkins so profuse on the wild Hazel in the hedgerows adjoining the plantation. With the object of seeing whether the wild pollen was capable of fertilising the Cobs, I examined a number of the female blooms of the latter under the microscope in March. Where the blooms were taken from trees separated from the hedgerow only by the width of a headland they were seen to be freely sprinkled with pollen grains. Blooms taken from trees more towards the centre of the plantation showed only a few pollen-grains, and in many cases none. The crop now hanging seems to bear out this observation there being most Nuts on the trees near the hedgerow, whilst there is a plentiful sprinkling further in the plantation. At the time when the pollen was ripe there was a strong wind blowing from the hedgerow across the plantation, so that conditions were favourable to the wild pollen reaching the cultivated trees. Some of the wild catkin bearing branches were cut off and hung in the Cobnut trees, but there is no evidence to prove whether this has been of use or not. I have little confidence in the plan, because most of the pollen is shed in the process of collecting the bunches, and the catkins soon die after they are taken from the trees. *Walter Cooper.*

of Peas is to allow plenty of room both between the plants and the rows. This year we grew eight rows in trenches, each 110 yards in length. Besides the variety named above, we grew Duke of Albany, Quite Content, Distinction, and Autocrat, which form a good succession. By allowing ample room between the rows, other crops, such as Beetroot, Carrots, and Cauliflowers, can be successfully grown between Peas. *Frank Beckett.*

CROPPING GLASS HOUSES WITH VEGETABLES IN WINTER.

In view of the scarcity of fuel for glasshouses, many kinds of outdoor flowering plants will be missed from most establishments during the coming winter, and many houses will be free for the cultivation of useful food crops. It may be necessary to utilise a little fire heat, but only the minimum amount should be used. Few crops pay better than Tomatos in winter, provided the plants are sufficiently advanced to ensure a full crop being set in November. Plants for this purpose should be ready for transference

FIG. 55.—PEAS GROWN IN TRENCHES AT ALDENHAM HOUSE GARDENS. THE VARIETY IS DISTINCTION; THE CARROT MATCHLESS PERFECTION.

ON INCREASED FOOD PRODUCTION.

PLANTING PEAS IN TRENCHES.

Though the cultivation of Peas in prepared trenches by no means an original method, it is not nearly so generally practised as it deserves, and there are some excellent reasons why it should be more widely adopted. Peas grown in this way are practically proof against drought, and a potato manure. The value of trenches lies in the fact that by excavating the soil to a good depth, and filling in the excavation either with suitable soil or well-decayed farmyard manure, the roots are provided with a deep root-run, and in dry weather can be supplied much more readily than when the plants are growing on the flat. We cultivate practically the whole of our culinary Peas in this way, with the best possible results. At the time of writing (August 27th) we are picking a plentiful supply from a long row of "Edwin Beckett," which we commenced to gather from the first week in June. The present yield is, of course, from secondary growth.

The chief point to observe in the cultivation of Peas is to allow plenty of room both between the plants and the rows. This year we grew eight rows in trenches, each 110 yards in length. Besides the variety named above, we grew Duke of Albany, Quite Content, Distinction, and Autocrat, which form a good succession. By allowing ample room between the rows, other crops, such as Beetroot, Carrots, and Cauliflowers, can be successfully grown between Peas. *Frank Beckett.*

CROPPING GLASS HOUSES WITH VEGETABLES IN WINTER.

In view of the scarcity of fuel for glasshouses, many kinds of outdoor flowering plants will be missed from most establishments during the coming winter, and many houses will be free for the cultivation of useful food crops. It may be necessary to utilise a little fire heat, but only the minimum amount should be used. Few crops pay better than Tomatos in winter, provided the plants are sufficiently advanced to ensure a full crop being set in November. Plants for this purpose should be ready for transference

through the surface, apply a light top-dressing of rich soil. The top growth should be carefully thinned, stopped and tied as necessary throughout the winter. Crowding of the plants should never be permitted; remove deformed fruits as soon as they appear. A temperature of 70° is suitable, but it may be allowed to drop to 65° during cold nights.

French Beans may be grown in quantity during the late autumn, but they are seldom profitable sown later than the middle of October. Pots 7 inches in diameter are best for late crops, and the plants should be grown to within 18 inches of the roof-glass in a house having a temperature of 60°. Good results may be obtained from sowings made early in January, either in beds or pots. From this sowing pods should be ready to gather about the last week in February, when choice vegetables are scarce. In order to maintain a regular supply, a fresh sowing should be made every ten days, and this crop should prove remunerative as time advances in spring and less fire-heat becomes necessary. The Belfast and Osborn's Forcing are good early varieties and prolific croppers.

Glass-houses may also be used in winter for the growing of salad plants, such as Lettuce and Endive, without fire-heat, except when very severe frosts occur, when sufficient heat should be afforded to protect the crops from injury. For winter crops several sowings should be made in September and the seedlings transplanted as soon as they are large enough to handle. If once allowed to become drawn in the seed beds they will be of very little value as a winter crop. Rich soil is necessary to ensure quick growth, and, during the autumn and early winter, a liberal supply of soft water should be given. Golden Ball, Little Gott, Monument, and Maximum are suitable sorts. The last two varieties are good for autumn and winter cropping in the order named.—*John Dunn.*

FRUIT REGISTER.

A NEW LATE RASPBERRY.

MESSRS. STORRIE AND STORRIE, Glencarse, Perthshire, have sent us fruiting sprays of their new Storrie's Excelsior Perpetual Raspberry. In this variety the canes begin to produce ripe fruits from the top laterals downwards, and each succeeding lateral, as in the samples received, shows ripe fruit at the apex, flowers at the base, and fruits in different stages of development between. The result is that ripe fruit may be gathered continuously during summer and autumn. The fruit is large and finely flavoured, and the canes will grow to a height of 7 to 8 feet in ordinary garden soil.

PEACHES ON WALLS IN THE OPEN.

ONE of the best early Peaches on our open walls facing south-east is Duke of York, which ripened medium-sized fruits of good flavour and colour at the end of July. Peregrine followed a fortnight later with handsome, highly-coloured, good-flavoured fruits, some of which weighed 8 ounces each. This variety is one of the best Peaches for growing both indoors and in the open. Owing to cold winds [illegible] and other varieties were affected by [illegible] This variety was immune, and has [illegible] with free from red spider. The variety Barrington has, up to this season, done well, but the dry weather of June retarded its growth, and there are very few fruits. The same is true of Crimson Galande, one of the best outdoor Peaches in ordinary seasons. Trees of Alexander Noblesse are carrying fair crops of good sized fruit, and have made good growth free from red spider. Royal George is not a success here; the fruit is woolly and the tree is very susceptible to blight. Violette Hâtive is our best and latest variety; the tree is quite hardy and never fails to carry a medium crop of good sized, well-flavoured fruits. Early Rivers Nectarine ripened choice fruit on a south wall at the end of July. All the trees are free from blister, having been sprayed with Bordeaux mixture a short time before the flower buds expanded.—*A. B. Wadds, Englefield Gardens, Reading.*

NOTES ON IRISES.

IRIS SPURIA.

IT has long been apparent that the name of spuria covers a number of local forms of an Iris which is widely distributed over Europe, and, indeed, in Asia. Herbarium specimens are of small value in comparing the various forms, for the growth of the different plants varies considerably according to the conditions of soil and climate in which they are grown, and, moreover, the same plant may differ appreciably from one season to the next, as conditions of heat and moisture are seldom identical in two consecutive years.

It has at length become possible to obtain plants from most of the known European habitats of this species, and to grow them side by side under conditions much more nearly identical than those in nature. It cannot be certain that this comparison is entirely satisfactory, for there still remains the possibility that some of those forms vary from seed, and that the one or two plants collected in any locality were therefore not representative of only one of the forms to be found in that district. However, bearing in mind this possibility, which can only be investigated by raising a number of seedlings from each locality, the various local forms seem to fall into three groups.

I. The plants are dwarf and slender, and usually produce only two flowers. The reduced leaves on the stem are narrow and tapering, and entirely clothe the stem. This form is found near Agde, in the Department of Hérault, in the South of France, near l'Hermenault in Vendée on the west coast of France, and near Madrid.

II. The plants are stouter and slightly taller than those of the first group, and the stems produce one or two lateral flowers set close below the terminal head. The reduced leaves are broader and less gradually tapering, but in this group, too, they entirely clothe the stem. Specimens of this form are found in the marshy meadows between Hyères and the Mediterranean, on the Danish island of Saltholm, in one locality in the fens of Lincolnshire, and near Algiers. I have not myself visited the habitat in the fens, but there seems no doubt that the plant is really wild there, though it was unknown to Bentham and Hooker.

III. The third group consists of taller plants, with the clusters of flowers and the reduced leaves set much further apart on the stems, so that the internodes are always uncovered for some distance. This form occurs at Trebur, near Darmstadt, and also near Perth, and in Hungary, and it is presumably the same form that was named subbarbata by Joo.

There is practically no variation in the actual flowers, though the shade of blue differs a little in different specimens.

So far as my experience of the plants goes, I should be inclined to expect that seedlings of groups I. and II. might be found to be indistinguishable, or to contain specimens of both forms, but that III. would remain distinct.—*W. R. Dykes, Charterhouse, Godalming.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Ripening Onions.—The long period of bright, sunny weather has been favourable to the maturation of Onions generally. All thick-necked bulbs, which never keep, with foliage erect, should have their stems twisted down to check top growth and assist in hastening the swelling and ripening of the bulbs. The sooner those with their tops nearly or quite brown are cleared off the moist ground the better, otherwise they may start rooting afresh, and this will impair their keeping qualities. The bulbs must not, however, be stored till they are thoroughly ripened by being laid thinly on mats, sunny walks, greenhouse stages, or shelves of comparatively empty houses. The old-fashioned plan of roping Onions and suspending them in airy sheds is still the best method. Tripoli Onions are invariably the worst keepers, and should be used first. After these those of the White Spanish type and other varieties with flat, straw-coloured bulbs should be used. This season, such late-keeping varieties as Brown Globe, The Wroxton, and James Keeping will be specially valuable.

Winter Spinach.—If from any cause the seed sown in August has failed to germinate, more should be sown at once. On land with warm subsoils these later sowings sometimes succeed the best, but, as a rule, the earliest-raised plants prove the most serviceable, and every care should therefore be taken of them. Transplanting may safely be done in showery weather, and for this reason it is advisable to thin out seedlings very lightly where they are crowded and thin finally when the plants are large enough to be dibbled out. Sprinklings of soot and frequent surface hoeings have a most beneficial effect on Spinach.

Tomatos.—Outdoor Tomatos have grown well and are fruiting heavily, very little disease being apparent. Should fine weather continue for a few weeks longer the fruits will ripen rapidly. All superfluous growths should be kept closely cut away, and where the leaves smother the trusses these should be thinned out to let the fruits have full exposure to sunlight. Too often the leaves are removed wholesale, but this is a mistake, as the loss of foliage either from disease or premature removal checks the growth of the fruits and also spoils their quality. Let the ripening for the present be natural and, if much of the fruit still remains in a comparatively green state when cold weather may reasonably be anticipated, the trusses may be cut off and the greater portion of the fruits ripened in a dry, warm house. Keep the roots well supplied with liquid stimulants and the top growth as dry as possible.

General Remarks.—This has been a fairly good season for the growth of all kinds of kitchen garden crops, and of weeds as well. Besides clearing off crops that are no longer profitable and storing others for winter, there is much work to be done in getting the land free from weeds while the sun is still strong enough to dry them quickly. After September this work becomes much more tedious and expensive. It is surprising what constant hoeing and scarifying the surface soil will do in clearing the worst cases of foul land. Late crops that have been put out recently should be encouraged to make growth while the warm weather lasts. Applications of liquid manure will assist all crops, as they require an abundance of moisture while making growth.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

Selection of Trees for Planting. — The selection of fruit trees for planting is an all-important matter, and one that calls for careful attention. I advise that it be attended to as

soon as possible after this date. The trees should be selected in the nursery, for it is only by this means that specimens can be chosen to suit any given position or locality. I like to see the trees growing; it is an education to do this, and one cannot learn too much from the fruit tree expert. It is preferable to obtain trees from exposed situations, where they are exposed to the wind from almost every quarter. This tends towards a hardier constitution. My advice is not to be guided by the vigour of any kind of fruit tree so much as by its uniformity of growth and symmetry. If often happens that the district is, to some extent, strange to the person in charge. When this is the case, find out beforehand what varieties of fruit do best in that particular district and select accordingly. When visiting a fruit nursery make it a practice to inspect the trees in a quarter that has been drawn upon the previous year, where, as a matter of course, the trees stand further apart and can be viewed easily. Besides, these trees have had more exposure, and possibly, too, not so much manurial stimulants in the past season. True, such trees may cost a little more, but it will be money well spent.

Trained Fruit Trees.—In selecting trained trees, such as Peaches and Nectarines, avoid those with a central leader, as these are not so likely to form well-balanced specimens in the near future. Always watch for any symptoms of canker and reject such trees as are affected. Where there is room it is preferable to have two trees of any given variety rather than one only. If I purchase Cherries and Plums as fan shaped trees I eventually get them into the horizontal form, for on our soil Cherries do better when horizontally trained. In the case of Pears, horizontally trained trees are preferable, for fan trained examples cannot at all times be formed into well balanced specimens. For quickly filling a wall both single and double cordons (on the gridiron forms are stout) to be recommended. This is great help in furnishing a wall as quickly as possible, and the somewhat additional cost in the first instance is soon well repaid by the quicker return in crops of fruit. With respect to pyramids, the trees should be well furnished and well balanced also. Trees that have been grown at a fairly good distance apart are much to be preferred even if not quite so tall for their age.

Bush and Standard Fruit Trees. Specimens marks apply to dwarf Apple on the Paradise stock. The true secret with all these trees to get them well established at the commencement. In selecting standard trees always choose those with clean, well-developed stems. There is often a great variation in the trees, but the cleanest in the stem are the best to choose, even if somewhat dearer than others.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to SIR JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Odontoglossum.—A few Odontoglossums have started well into growth, and where a representative collection of these Orchids is cultivated some of the plants require attention at the roots at intervals throughout the year. But the month of September is the best time for general repotting or replenishing the surface materials, as may be found necessary. Plants that have grown to the sides of the pots, and those that are in old compost and have become exhausted should be repotted. The best time for this operation is when the young growths are from 2 to 3 inches long, as at this stage new roots are developing from their bases. The plants should be turned out of the pots and the old materials shaken from the roots. Decayed roots should be cut away, also old, leafless pseudo bulbs, leaving two or three pseudo-bulbs behind the young growths. Small, healthy plants are best repotted annually, and this should be done without much root disturbance, while plants growing in 5 or 6 inch pots that were repotted last year and with compost in good condition should not be disturbed, but some of the materials should be carefully picked from the surface and replaced by fresh. In repotting, select a clean pot that will accommodate the plant for two seasons, and fill it to one-third its depth with clean crocks, covering these with either a small quantity of Sphagnum moss or the rougher portions of the compost. Keep the back part of the plant near to the side of the pot, and the base just level with the rim; press the soil with moderate firmness against the rhizome and between the roots. When the plant is potted the front of it should rest on the surface of the compost. A suitable rooting medium for Odontoglossums consists of equal parts of Osmunda fibre and A1 fibre, with chopped Sphagnum moss, half-decayed oak leaves, and crushed crocks added. After the plants are repotted they should be placed in the house and watered with a can having a fine rose, and shaded from bright sunshine. Keep the atmosphere humid by damping the bare spaces whenever they become dry; on bright days a light spraying overhead will be beneficial. Water the plants with extra care until the roots have grown freely into the new compost. Plants that are in a dormant condition should not be repotted until the young roots have made suitable growth.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Lachenalia.—The Lachenalia is a desirable plant to grow in these times of fuel shortage, as it requires absolutely cool treatment. Bulbs may be potted now in comparatively small pots filled with a rich, open compost. The plant is very suitable for growing in hanging baskets or pans. When the bulbs are potted water them and place them in a cool house or pit, using fire heat only when there is danger of severe frost.

Chrysanthemums. These plants should receive their final stopping so far as the weather permits day or two, but the buds should be ready for the first autumn shoots there be danger of frost. Plants of the large flowered kinds should be placed under glass as soon as the buds show colour, as rains or heavy dews will cause the petals to damp. Late flowering varieties will remain out of doors for several weeks later than those of the main batch, but they should be placed in a position where covering at short notice may easily be placed over them when frost is imminent.

Begonia Gloire de Lorraine.—Let this Begonia have plenty of water and stimulants, the latter on two or three occasions weekly. The young shoots are growing freely and need constant attention in tying to keep the plants shapely. If less fire heat than usual is employed let there be a corresponding reduction of moisture in the atmosphere. If the plants are not required to flower early pick off the blooms for the present.

Climbing Roses. The final thinning of the shoots of all climbing Roses should be done now in order that those left for flowering may become thoroughly matured before the winter. The roots should still be supplied with an abundance of water and stimulants; neglect in this matter is often the cause of an attack of mildew. Should this disease appear on the foliage dust the plants with flowers of sulphur.

FRUITS UNDER GLASS

By W. J. GEISE, Gardener to Mrs. DEMESSIE, Keele Hall, Newcastle, Staffordshire.

Melons. Late Melon plants in houses or pits are swelling their fruits, and require a little warmth in the bottom pipes to maintain the requisite temperature. Every advantage should be taken of sunheat, by closing the house early, but the nights are very chilly, and it is therefore necessary to supplement this with a little fire heat, as good Melons cannot be obtained if the temperature is allowed to fall much below 70°. Syringing the foliage of Melons (as I have before remarked) is often carried to excess, and, provided the foliage is clean, the practice should now be discontinued. The paths, walls, and other bare spaces may be damped on fine mornings, and again when the house is closed, but the damping must be strictly in accordance with the weather. Remove all superfluous shoots that would obstruct the light. Top-dress the beds with a thin layer of fresh loam and a little bone-meal or fine, old lime rubble. As large Melons are not desirable at this period manure should not be used; rather aim at producing medium-sized, well-flavoured fruits averaging 4 lbs. in weight.

Melons in Frames.—Melons in frames should be just approaching the ripening stage. If the frames are furnished with hot-water pipes there will be no difficulty in obtaining fruits of a rich flavour by high temperature and dry atmosphere, essential to obtain finely finished specimens. Very little moisture is required, but just sufficient is needed on bright mornings to keep the foliage from flagging. Water should be withheld at the roots and the soil gradually allowed to become dry when the fruits are ripening; it is a good plan to arrange the fruits above the foliage by placing them on inverted flower pots, as the quality and flavour is considerably improved by full exposure to the sun. Keep the glass, both inside and out, perfectly clean.

Tomatos.—Winter-fruiting Tomatos should be shifted at once into large pots. It is not advisable to fill the receptacles with soil, but it should be made firm; leave ample room in the pot for adding top dressings on several occasions. Keep the house closed for a few days until the roots are established in the fresh compost, then admit air freely, to encourage the development of short jointed, sturdy growths.

THE FLOWER GARDEN.

By E. F. HOUGHTON, Gardener to the Earl of RADNOR, Coleshill, Twyngham, East Isbury.

Border Pinks.—Varieties of Border Pinks, as well as some spreading species, are at this time of the year easily increased by division. If the atmosphere has been most numberless roots will have formed along the stems, but even where no roots have formed the pipings will root with certainty. Notch lines in the ground for their reception, and it will be productive of nice firm growth if some old potting material is placed over the stems before filling in the soil. They may be watered, but at this season it is not essential, especially if the soil is pressed very firmly. There is a very pretty form of Cyclops which I have had off and on for many years, which also should be propagated now, but this I increase by means of cuttings inserted in 5 inch or 6 inch pots which are stood in the Carnation house till spring, when they are ready to plant out.

Carnations. If Carnations were layered early the young plants are now ready to transplant into beds where they are to flower. The benefit of early planting, apart from strengthening the plants, is that frost has no evil effect, as is so evident in the case of those planted late, in lifting them partially out of the ground. In 1915, when time to do things right seemed impossible, I planted Carnations in undug and otherwise unprepared ground, and nothing could have done better than they did. Not only were usual border varieties included, but also show sorts and Picotees, generally restricted to pot culture. The lesson from that is that Carnations must have a very firm soil for rooting in, and consequently, after digging, the ground should be made firm by foot pressure before planting, and very porous soil be made firm after planting. It is to be remarked that the Carnation is semi fruticose, and therefore must not be planted deep, with the further caution that strong plants may require support until established. Instead of inserting a short stick parallel to the plant for this purpose I prefer to put it in askant and secure the plant to it with a single tie where it touches the stem. A percentage of layers should be potted in order to have spare plants to fill blanks in spring, and now is also a good time to pot up the whole stock where spring planting is the custom. During much rain the plants should be placed in frames.

EDITORIAL NOTICE.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, SEPTEMBER 10—
Roy. Hort. Soc. Comms. meet and National Dahlia Soc. (combined show).
WEDNESDAY, SEPTEMBER 11—
Acton Allotment Show.
FRIDAY, SEPTEMBER 13—
Southend Food Exhibition (2 days)
TUESDAY, SEPTEMBER 24—
Roy. Hort. Soc. Comms. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 58.4°.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, September 5, 10 a.m., Bar. 29.8, temp. 61. Weather—Close and damp.

SALES FOR THE ENSUING WEEK.

TUESDAY—
Sale of Winter Blooming Heaths and Greenhouse Plants at Burnt Ash Road Nurseries, Lee, S.E., by Protheroe & Morris, at 11 o'clock.
WEDNESDAY—
Sale of Bulbs, Palm Seeds, &c., at 67 to 68, Cheapside, by Protheroe & Morris, at 1 o'clock.

Wood.

We are so familiar with the uses to which wood is put that the amazing and varied properties which timber possesses rarely if ever excite our wonder. Yet those properties of strength, elasticity, and durability confer on timber, as is pointed out by Prof. Groom,* a superiority over all other structural material.

Suitably used and treated, wood is more durable than iron, and may be subjected to processes which enable it to withstand temperatures at which iron becomes a molten fluid. By its disintegration the fibre for paper and cordage is obtained, and by distillation or partial decomposition of wood all manner of precious chemicals—alcohols of various kinds, acetone (so necessary for munition work), formalin (one of the chief antiseptics), turpentine, as well as dyes, scents, and drugs—are produced.

In spite of the ever-extending use of metals, wood holds it own, and every year the consumption of timber per head of population steadily rises

The insatiable demand of this country for wood is revealed by the import returns. As Prof. Groom points out, the value of timber imported in 1913 was: Soft wood, 32 million pounds sterling, and hard wood, 10 million; and to this must be added the not inconsiderable value of the home-grown timber which was felled.

Since the supplies of soft wood and their accessibility are decreasing, it is evident that the price of soft wood of large dimensions—Douglas Fir, Pitch Pine, and Scots Pine—is bound to increase. It is, therefore, important, as Prof. Groom insists, that increased economy and production be practised, and it will also be necessary to substitute, as time goes on, available hard woods for soft wood. In spite of the enormous consumption of timber in this country we cannot be charged with extravagance, for our annual consumption per head of population is less than that of any other great Power except Italy. Whereas we only use 14 cubic feet per head of population, France uses 24.6, Germany 36.6, Canada 192, and the United States 260. Prof. Groom insists that afforestation must be practised in order to provide for home needs, and points out that our climate is well suited to the growth of Coniferous—that is, soft-wooded timbers. The timber produced here is good, and can be used for many purposes. Scots Pine grown even in the South of England is good enough for wood paving, and the slow-growing trees of Scotland produce timber good enough for use in the construction of the vital parts of aeroplanes. The difference between the value of timber from trees of a given species—Scots Pine, for example—is due not to differences in quality of woody substance, but to the relative amounts of spring and autumn wood formed each year. Spring wood has relatively thin walls and large spaces, autumn wood thicker walls and smaller spaces. Since climate determines the relative amounts of spring and autumn wood formed in each annual ring, it is possible to predict with considerable accuracy the properties and value of the timber grown under different climatic conditions. In this way Germany, with its well-regulated forests and research laboratories, was able to ascertain at once from which forests timber suitable for use in aeroplane construction was to be obtained.

Prof. Groom gives an interesting example of the economic loss which follows from the present confusion in nomenclature of certain hard woods, such as mahogany. Wood from various trees is sold in this country as West African mahogany. Many of these spurious mahoganies come from the German Cameroons. Germany sent us false mahogany which enjoyed the prestige of the name, and so realised a better price than if it had been sold under its proper name. The importance of proper seasoning of timber is due to the fact that many of the desirable qualities of timber vary in inverse proportions to the amount of water which it contains. On the other hand, the presence of considerable quantities of water in timber permits of its being manipulated, as, for example, by compression to form railroad keys or bent for use in furniture-making. Seasoning has, of course, another effect of great value, that of rendering wood less apt to decay. The loss from decay in unseasoned wood such as that generally used for pitprops is prodigious. For instance, it has been estimated that if the pitwood in the United States were treated with antiseptics before use there would be a saving of 50 per cent., or of 50 million cubic feet per annum. The wastage of pitwood may in some cases be so great that props require to be replaced in from 4 to 12 weeks, whereas creosoted props in the same mine may last 8 years. We cannot here do more than give a brief summary of Prof. Groom's valuable paper, but we would recommend all who are interested in the use of wood and the development of the timber resources of the Empire to procure a copy and peruse it with attention.

* "Timber Industry," by Percy Groom, D.Sc., *Journ. of Roy. Soc. of Arts*, July 5, 1918.

National Dahlia Society.—The annual exhibition of the National Dahlia Society will be held in the Drill Hall, Buckingham Gate, Westminster, on Tuesday, September 10, in conjunction with the Royal Horticultural Society's fortnightly meeting.

Garden Judges. — Some comments upon the action of a competitor in interfering with the judges at the recent competition for prizes for the best gardens in the Burgh of Kirkcudbright were made in the judges' report submitted to a recent meeting of the Town Council. It was alleged that one of the competitors had interfered by offering the judges some uncalled for advice regarding their duties. The Council agreed to intimate that exhibitors interfering with the judges in their duties would be disqualified.

Prices for Vegetable Marrows.—The Food Controller has made an Order fixing the following maximum prices for Vegetable Marrows, which are largely used in the manufacture of jam:—Grower's price on sales to a licensed jam manufacturer (f.o.r. at grower's station), £6 per ton; grower's price to retailers (delivered ex market or to retailer's premises), £6 10s. per ton; grower's price on any other sale except retail sale (f.o.r. grower's station), £5 10s. per ton; wholesale dealer's price (delivered ex market or to the buyer's premises), £6 10s. per ton. Retail Sales: One penny per lb. or any part of a lb., with a maximum of 7d. for any single Marrow. No charge for delivery is permitted. In a season when the fruit crop is poor Marrows are also short of the demand. It has, therefore, been arranged that jam manufacturers shall be at liberty to buy for jam making, in priority to any other purpose, any Vegetable Marrows in the hands of growers or wholesale dealers on tendering the maximum price. If the Marrows are in the market this price will be £6 10s. The Order, which came into operation on August 28, cancels contracts above the maximum price: it does not apply to cooked, preserved, or Custard Marrows, nor to Marrows grown in Ireland.

Flowers in Season.—Mr A. DAWKINS, King's Road, Chelsea, sends flowering shoots of his new Calceolaria Buttercup, which gained the R.H.S. Award of Merit on May 28, 1918, and was illustrated in fig. 97, in our issue for June 1, 1918. The inflorescences are exceedingly floriferous, the blossoms being rich yellow. Mr. DAWKINS states that "the branches were cut from one of the plants exhibited at the Drill Hall on May 28 last. After flowering in the greenhouse the plant was cut back and planted in a border: it commenced to flower early in August, and is still in full bloom."

Jam.—An Order amending the Jam (Prices) No. 2 Order, 1918, came into operation on Monday last. Prices show an advance of 1½d. to 3d. per lb. on those which have hitherto been in force. New varieties of jam have been added to the Schedule of the Amended Order. Rhubarb jam and Rhubarb mixed with other fruit can still be bought for 11d. a lb., and Gooseberry and Apple mixed is the same price. Jam mixtures not specifically scheduled are 10½d., which is a halfpenny up; and other prices range from 11½d. to 1s. 2d., Cherry (a penny up) and Strawberry being bracketed at the latter figure. Marmalade is 1s., as before: Raspberry, Black Currant, and Loganberry, at 1s. 1½d., are un-

changed; Red Currant and Plum are each 1s. 0½d.; Apricot and Pineapple are increased ½d., now making 1s. 1½d.; Blackberry, Peach, and Greengage have risen 1d., Peach being 1s. 1½d., and Blackberry and Greengage 1s. 0½d; while Damson and Plum, 2d. dearer, are on the 1s. 0½d. level. Mixtures with Melon are listed at 1s. 1½d.

Destruction of Rats.—The Ministry of Food has issued an Order giving power to local authorities to take such measures as may appear to them to be necessary to secure the destruction of rats, and making it compulsory for all persons concerned to comply with the regulations issued under the Order. The intention of the Food Controller, we understand, is to permit local authorities to decide for themselves what steps are most likely to be successful in their own districts.

Food for Bees in Winter.—Bee-keepers are recommended by the Food Production Department to inspect their stocks immediately. Those which are weak and have less than five seams of bees should be united to form strong colonies of not fewer than eight seams, and all those which are short of food should have a quantity of syrup fed to them for immediate storage in the combs. This syrup can be made by dissolving each one pound cake of candy in 10 ozs. of water by heating over the fire. The manufacturers of this candy, Messrs. Jas. Passmore, Ltd., Blackfriars Road, London, S.E., are receiving large numbers of orders from bee-keepers, who are apparently ordering sufficient supplies not only for autumn feeding, but to last them right on the winter and spring. The supply of candy so far available may prove insufficient for both purposes, and as a result many bee-keepers, especially those who have nucleus stocks, may be unable to obtain any for immediate use. This candy has been manufactured solely to supply present demands, and, under these circumstances, bee-keepers should obtain just now only those supplies necessary for immediate syrup-feeding. The candy required for winter and spring feeding should be ordered at a later date.

Food for Pigs.—The War Emergency Committee of the Royal Agricultural Society, having called the attention of the Ministry of Food to the difficulty of obtaining food for pigs, has been informed that priority certificates for millers' offals are now issued by live stock commissioners in respect of pigs. Allocations of Palm kernel cake are also being made to county feeding-stuffs committees for pig feeding, and persons desirous of obtaining either cake or millers' offals should apply to the live stock commissioners of their area for the certificate.

Caterpillar Plagues and Their Prevention. In view of the immense amount of damage done to fruit and vegetable crops by caterpillars the Food Production Department directs attention to the fact that if all fruit growers would combine in a great preventive campaign against fruit tree pests they would be insured against a repetition of this year's attack, which caused much damage in gardens and orchards. It cannot be too often stated that the greater part of the ills that afflict garden, market garden, and orchard crops can be obviated by preventive measures taken in due season. To prevent a plague of caterpillars next spring, and summer standard and bush standard fruit trees should be grease-banded now and other precautions taken during the winter and spring. As soon as possible, and not later than the end of September, the grease-bands should be applied. Early in October the wingless females of the Winter Moth family begin to crawl up the trunks of the trees and to lay their eggs on spurs and twigs. In the spring these eggs will hatch into small caterpillars, and these caterpillars will soon strip the trees of their leaves, to the great detriment of the immediate fruit crop and the eventual health of the tree. The best method of preventing these attacks is to tie bands of stout, grease-proof paper smeared with a sticky preparation sold for the purpose around the trunks of the trees. The moths in attempting to climb the trunks become entangled in the grease and eventually die. Fresh grease should be smeared over the bands every four or five weeks, or whenever the outside surface has become dry from exposure.

Harvesting Sunflower Seed.—Sunflower seed will ripen on the open in a fine autumn, but care must be taken to protect it from birds and to prevent the ripe seed from falling on the ground. A small piece of muslin should be tied over each head, when the planting is small. When the head shrivels and the seeds are ripe, the plants should be cut at the ground level, and stood with their heads uppermost like sheaves of corn. When the heads are thoroughly dry the seed should be rubbed out, the remaining stock fed to cattle or used for litter, and the seed stored in bags in a dry place. Before winter sets in, the seed should be carefully picked over, and all that is not perfectly sound rejected. It is then ready for sowing in the spring. If the plants are cut at the ground level as soon as the seed is ripe and tied in an inverted bundle, the seed will keep until the heads shrivel, the bundle is untied and placed in single layers on the floor of a shed open in the evening, leaving the doors and windows open. When the fire is made up in the morning, the heads should be removed and replaced in the evening.

War Item. The Canonbie Horticultural Society held a highly successful Floral Fete at the end of August, and realised a sum of about £150 for the Scottish Red Cross Funds.

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables in *Gardeners' Chronicle* for August 3, p. 42.)

(*Continued from p. 92.*)

3. ENGLAND, E.

OXFORDSHIRE.—The fruit crops this season are disappointing. Apple trees developed plenty of bloom, but the fruits failed to set. This is largely owing to the scarcity of bees in this district, most of the stocks have died out. There are no Pears. Plum trees flowered freely, but cold winds injured the bloom, except in the case of trees sheltered by a south wall, and these are carrying good crops. Black and Red Currants

FIG. 96.—CAULIFLOWER VEGETABLE MARROW VARIETY (see p. 104).

are good and clean. There was a splendid crop of Raspberries (Superlative and of Gooseberries. Strawberries were a good crop, but owing to the drought the season did not last long. Our soil is a fine loam on lime stone. *William J. Sheat, Mid-dleton Park, Bicester.*

The fruit crops this season are very much under the average. Apples and Plums, although the trees bloomed profusely, failed to set. There was a sprinkling of Apples on young trees, but Plums are a complete failure. The latter rotted apples also to Pears; for some reason the trees failed to bloom. Peaches provide much the best fruit crop in these gardens. Small fruits, on the whole, gave average crops, but suffered from the prolonged drought. Early and mid-season Strawberries bore good crops,

but late varieties suffered from drought. I never remember a worse season for insect pests, particularly caterpillars and aphis. Unfortunately, shortage of labour has prevented measures being taken for their destruction. The soil is light, shallow loam, on lime-stone brash. *Ben. Campbell, Combury Park Gardens, Chadlbury.*

—— Apple trees are yielding an average crop; they are fairly free from blight. We have no Pears. Plums and Cherries can only be described as fair, but Gooseberries, Red Currants, and Strawberries were plentiful and good. The soil is a light loam on gravel and chalk. *J. A. Hall, Shaplake Court Gardens, Henley-on-Thame.*

—— This is a bad fruit year. Plum trees, Cherries, and bush fruits were in full bloom in April when snowstorms and cold nights did much damage. Our Apple trees bore very little bloom this year; the temperature at flowering time was on one day 38° in the shade, so that what bloom existed had little chance of setting. *A. J. Long, Wyfold Court Gardens, near Reading.*

—— The fruit crops here are the worst I have ever known. Scarcely any blossom developed on Pear trees. Apple blossom was also sparse and weak, and even the most promising trees set very few fruits. On the contrary, we had a wealth of Plum blossom, but, unfortunately, frost and snow prevailed at the setting stage. Cherries flowered abundantly, but notwithstanding the absence of frost during their flowering period they failed to set fruit, with the exception of the Morello variety, of which we had a fair crop. Excepting Strawberries, Raspberries, Loganberries and Wineberries, soft fruits have been disappointing. Fortunately, we have abundant crops of stone fruits under glass. The soil here is a heavy marl, the subsoil chalk, being near the surface. *Frank J. Clark, Aston Rowant Gardens, Aston Rowant.*

—— Apple trees did not bloom well, probably on account of the heavy crops they carried last year. Wall trees blossomed freely, but the cold, frosty nights of April injured flowers of Pears, Plums, and Cherries. Apricots set fairly well, but although under glass coping and canvas, many of the young fruits were destroyed by frost. *C. E. Munday, Nuneham Park Gardens, near Oxford.*

5. SOUTHERN COUNTIES.

BERKSHIRE.—With the exception of bush fruits and Strawberries, the fruit crops are comparative failures, owing chiefly to the bad weather prevailing at the time of flowering. Apples and Pears, with the exception of one or two kinds, are very scarce, and we have practically no Plums, although the trees flowered well. *W. Miles, Caversham Park Gardens, Reading.*

—— The fruit crops in this neighbourhood are much below the average, especially as regards Apples and Pears; indeed, it is the worst season I have experienced in forty years. Some of the varieties showed plenty of flower, but it was late in developing. The only Pear trees carrying a crop are of the old Williams' Bon Chrétien variety. Plums are also scarce. Peaches and Nectarines are bearing good crops, while Apricots are the best for some years. Strawberries suffered much from the drought, and Raspberries were very disappointing, many of the canes dying back in the late spring, although they had previously looked healthy. Loganberries, Mulberries and bush fruits have borne good crops, but Black Currants were smaller than usual. *J. Howard, Basham Palace Gardens, Newbury.*

—— The fruit crops here, with the exception of small fruits and Peaches, are much under average. Pears are a failure. The trees showed the usual quantity of flowers in spring, but the blossoms were weak, and they dried up before pollination was effected. The heavy crop of 1917 must have had a weakening effect on the trees, and during the flowering period the weather was too dry. The soil here is of a light nature over a gravel subsoil. *J. Minty, Oakley Court Gardens, Windsor.*

—— Apples and Pears are scarce. Plums on the walls are bearing light crops. All bush fruits were good. Strawberries were small on account of the absence of rain. Peaches, Plums, and Apricots were in bloom in March, when we experienced frost and snow. Apples have fallen for want of rain; a few trees that are bearing are Beauty of Bath, Worcester Pear main, Lane's Prince Albert, Royal Jubilee, Bismarck, Mere de Menage, Ribston Pippin, and King of the Pippins. *A. B. Wadds, Engle field Gardens, Reading.*

DORSETSHIRE.—Pears and Plums this year are the greatest failures in my recollection. I have counted upwards of 50 trained wall Pear trees without a solitary fruit, and pyramid trees are quite as fruitless. Beurre d'Anjou on a south wall is the only variety bearing anything approaching a crop. The same remark applies to bush Apple trees, but in the orchard we have about one third of a crop. Cherries, both Sweet and Morello, have borne average crops, and are good in quality, and the same applies to Peaches and Nectarines but Apricots are a very light crop. Except Black Currants, which yielded badly, small fruits have been plentiful and good. Strawberries suffered from the drought in June, and were much under the average. Nuts of all kinds are a light crop. The soil is of a retentive nature, on both rock and clay subsoil. *T. Turton, Castle Gardens, Sherborne.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Double Cropping in the Lea Valley.—Your interesting article on double cropping in the Lea Valley, on p. 75, states that the report does not give the date at which the Potatoes were planted, nor that at which they were lifted. If you refer to the report you will find that it distinctly states that "the sets were planted, after sprouting, on January 20, and the crop was lifted on May 7. *A. D. Lister, Director, Experimental Station, Cheshunt.*

Potato Majestic. When Mr. Cuthbertson lectured on Potatoes at the Mansion House early this year he made special mention of a Potato named Majestic. As Mr. Cuthbertson's knowledge of Potatos is extensive, I at once obtained seed of this variety, and now regret I could not procure more, but that was not possible, as only a limited quantity was on the market. This variety is in every way all that was claimed for it. The growth is of medium height, the crop heavy, and the tubers clean, pebble shaped, and white, with very shallow eyes. When cooked the Potatos are floury, white, and of excellent flavour. *E. Molyneux, Swanmore Farm, Bishop's Waltham.*

Cultivation of Drug Plants.—In one of the London daily newspapers recently there was a short paragraph on the establishment of a company called the British Drug Farms and Distilleries, Ltd., for the growth of medicinal herbs in Cornwall, and establishing a college of horticulture in connection with the drug farm. It appears, therefore, that a serious effort is to be made to create a British drug industry and to maintain it. If this is the case in reality, it should in the future assist the nation to become independent of foreign supplies of raw material for one of its most vital needs, in addition to developing further our natural agricultural assets. It is indeed surprising that such a step has not been taken until now. *C. W. Howard.*

"Rogues" among Potatos (see p. 83).—Mr. Jackson calls attention to what I said about rogues in Potatos in one of my recent lectures. He thinks the rogues should be more mercifully treated than I advised because "some of them are entirely new sorts produced from the tuber itself . . . The Potato, like many other plants, has the power to produce new sorts vegetatively apart from seed." Perhaps Mr. Jackson will tell us of some examples of this. I have been looking for them for twenty-five years, and have not found any of importance. Colour variation I have found, e.g., I have found King Edward give tubers red in colour all over, which maintained that character when propagated in the usual way. It will be remembered that Northern Star has a touch of reddish-purple colour in the eye. I found a tuber once at a root of Northern Star with the eye-colour distributed over the whole tuber, that also remained constant when propagated. Many years ago a writer in a contemporary—a gentleman who now occupies a high position in the horticultural world—said that the way raisers got new varieties was by marking outstanding plants in their crops and working up stock from them! If Mr. Jackson or anyone else can give us indisputable evidence of such mutations as he writes about it will be welcome information to both raisers and scientific investigators. *W. Cuthbertson.*

Fruit Crops in Hertfordshire.—It may interest you to know that the Apple crop in Hertfordshire is not a failure. Most trees in these gardens are laden with fruit, and especially those of the varieties Lane's Prince Albert, Queen, Bramley Seedling, Newton Wonder, Stirling Castle, and Royal Jubilee. Dessert varieties are all fruiting heavily, with the exception of Cox's Orange Pippin and The Houblon. The crop of Pears on wall trees is below the average owing to a scarcity of bloom, but trees that bloomed have set fruits freely. Gage Plums are an excellent crop, and especially Early Transparent Gage and Oullin's Golden Gage. Plums Early Prolific and Jefferson are good, but other varieties are failures. Apricots, Morello Cherries and Peaches are average crops. Bush fruits were quite up to the average, with the exception of Red Currants. Nuts were never better. *T. Pateman, Node Gardens, Welwyn, Hertfordshire.*

SOCIETIES.

VEGETABLE SHOW AT DOVER.

AUGUST 23.—A successful show of allotment produce was held on the Sports Ground, Dover, on the 28th ult., in connection with a military display. The produce shown was of high quality, especially in the classes for Potatos, Onions, Carrots and Beets. The soil at the various camps is a flinty loam of not more than 8 inches in depth, upon pure chalk, and it was surprising to find such excellent produce as was exhibited.

Mushrooms are grown in quantity in the galleries of the old fortifications and also in the dungeons of the Castle, while on the chalky slopes overlooking Dover Harbour plants of Tomato Holmes' Supreme are carrying splendid crops. Sea Kale is extensively grown in the open and blanched in the subterranean chambers which abound in the old fortifications. Marrows also appear to luxuriate on the hot, arid slopes.

The cultivation at the various centres is under the direction of practical gardeners drawn from the ranks, and who in the past have superintended private establishments where considerable staffs of under-gardeners are kept.

The whole of the produce was judged by two local horticulturists and a representative of the Horticultural Division of the Food Production Department. The arrangements of the exhibition were carried out by 2nd Lieut. Grant White in a most business-like manner.

In 1917, within Dover Garrison, the acreage under cultivation was 35 acres, and in 1918 has increased to 60 acres.

The following was the total yield for 1917: Potatos, 150 tons; Brassica (Cabbage, Turnips, etc.), 420 tons; Vegetable Marrows, 6,300; Beans, 2 tons; Lettuce, 6,000 heads. The crops of 1918 promise to give even better results than 1917, and up to the present the total yield is: Potatos, 193 tons; Brassica (estimated), 600 tons; Vegetable Marrows 9,000; Beans, 4 tons; Lettuce, 10,000 heads. Roughly, 1,400 tons of vegetables have been grown in the garrison during 1917 and 1918, thereby releasing 156 railway wagons, or 7 trainloads, to carry foodstuffs for the civil population.

CHESTER PAXTON.

CONSIDERABLE impetus has been given to the allotment movement locally by the Chester Paxton Society's offer of prizes and cultural certificates for the heaviest cropped and best kept allotments. Considerably over a hundred allotment holders entered for these awards this year, with the result that more than 60 prizes and certificates have been awarded by the judges. Last year there were some 1,200 allotment gardens in the city and suburbs, and the number during the present year has been increased to nearly 1,550.

CROPS AND STOCK ON THE HOME FARM.

CLEARING UP THE HARVEST.

ON our 350 acres of arable land Wheat cutting commenced on July 31, and to-day (August 31) we are clearing up the Barley raking, which usually covers the latest operations. Although much of the Corn was laid and twisted, with patience and by using the binders one way in case of bad lands, the cutting was carried out quite satisfactorily, and the bulk of the harvest promises well. Where a Wheat rick is erected I like to see that a quantity of straw at once, as Wheat and rye comes it better if well dry in the rick, even when, as in our case, it is sold off the land in October. Barley, too, is not covered the day after the rick is built, as rain affects Barley straw more than that of any other cereal, especially when cut moist, and even when in shelves the straw does not be so noticeably as in the case of Oats or Wheat, therefore my advice is, that a Barley rick promptly. Oats are the worst of all cereals to manage well. If they are strongly set on the straw has extra large green nodes which contain much sap and take a long time to mature thoroughly. This is why Oats require a lot of field room. If Oats are carted too quickly, especially if grass, Thistles or weeds are in the sheaves, extra exposure is needed or the whole will ferment, ending in "musty." Corn which is noxious for seed and not very valuable for cattle. The straw too is deprecated for use as fodder. Some of the strong growing hybrid Oats are safer to these failings, but Black Tartarian is not nearly so liable to them as others. If there is any doubt about the condition of the rick watch the apex early in the morning, and if steam is coming through, and there is the slightest suspicion of anything wrong, delay the thatching. Use the bar 12 feet long thrust into the middle of the rick is useful for testing its condition; if it is quite cold, or nearly so, at the end of twenty-four hours, there is then no danger of heating.

After threshing, the straw ricks should be promptly thatched, as the straw is thereby kept in good condition. I have heard persons say, "Rake down the roof, it will be all right." This is not so, as rain seems to have the power of collecting in certain parts of the "roof" and then thoroughly wets the straw in that area and quickly discolours it. The saving short straw from the threshing machine, as well as the "hulls" (chaff covering of the grain) should be collected and kept dry.

Where threshed cereals of any kind are to be kept any length of time the grain should not remain in the sacks too long especially if on a cold or damp floor. Wheat quickly becomes "cold," and is then not in a good condition for grinding. All grain should be spread on a wood floor and turned occasionally, well ventilating the building by day when the weather is not foggy or wet. It is strange how quickly threshed Wheat attracts moisture. Growers of seed Corn should remember that before sale the grain must be tested for purity and germination at some establishment authorised for this purpose; no Corn may now be sold without a certificate of purity and germination. I fear too many farmers sow seed without cleansing it from weed seeds and spurious grains; all tested seed will be sold at its correct value, which is a step in the right direction.

EARLY SOWING OF WHEAT.

It is important that wherever harvest operations will allow, and the district does not suffer from drought in early autumn, Wheat should be sown early. Experience has shown that the advantages that accrue from early sowing in a normal season are often considerable. Light crops of Wheat due to late sowing are more frequent in many parts of the country than is realised. A smaller quantity of seed should be used when sowing early: 1½ bushel per acre sown in September will give as good a crop as 2 bushels sown in October, or 2½ bushels in November. There are similar advantages from early sowing in the case of Rye.

CLOVERS.

The seed sown with the Corn in the spring has a very irregular appearance. Some parts of a field may have a regular growth, while on others adjacent to the same field there are bare patches. No doubt the moist weather at the end of March and in the first half of April started the young plants into growth, and the subsequent unfavourable weather "matted" the seed, thus killing the growth. Italian Rye Grass or Trifolium may be sown this autumn, at the rate of 1 bushel of the former per acre, or 20 lbs. of the latter, will make good plants and provide a more regular crop either for sheep or cattle. *H. Molyneux Simmonds (Farm Bailiff to H.M. the King).*

NEW INVENTION.

FRUIT FARM PLOUGH.

MESSRS. J. B. CROFT AND W. P. SEABROOK have invented a handy implement that is especially designed for use in fruit plantations. It has an adjustable mould and movable handles, and it is drawn from a stake on the boom instead of from the horse, consequently when horse and plough are turned to the right hand to the next row the horse is not required to walk on the ploughed land, but passes to the right of the stake.

TRADE NOTES.

RECONSTRUCTION OF THE HORTICULTURAL TRADES ASSOCIATION.

UNDER the presidency of Mr. Alfred Watkins about one hundred and fifty members of the horticultural trade met in the Cambridge Room, Great Eastern Hotel, on Tuesday, September 3, to consider the subject of reconstructing the Horticultural Trades Association. The meeting was announced to commence at 2.30 p.m., but as that hour the president's address on the business of the annual meeting held in the morning was not finished, consequently the latter meeting could not be called to order until a quarter to 4. A common Holders' Association was discussed, with the result that the meeting eventually agreed to recommend to the Food Production Department a scheme whereby the allotment business should be worked through the retail seedsmen, who would be prepared to allow a rebate on quantities.

At the close of this discussion the president brought forward the matter of all absorbing interest to the reconstruction of the constitution of the H.T.A., and he suggested that the principles as set forth in the circulars sent out to the trade should be adopted, and that the details and rules be left for the consideration of a special committee. Mr. R. Wallace then outlined the scheme which commences with District or Local committees, who are to appoint representatives to County or Group Committees. The latter will elect representatives to the Central Committee. The Central Committee will decide into trade groups for the consideration and settlement of their own special affairs. The Central Committee will account the Executive Committee, which, while having no power to veto the findings of the Central Committee, will deal with all financial matters and see that the findings of the Central Committee are carried out. The Executive Committee will also appoint the secretary, rent offices, and appoint similar details.

Mr. Wallace is a most able speaker and he roused considerable enthusiasm. He was followed by Mr. Evans, of West Bromwich, who has been the moving spirit in connection with the reconstruction scheme. Mr. Evans made a great point of the need of co-operation to make the proposed new conditions a success, and he said that it would not suffice for a member to pay his subscription and then lose all interest in the work of the Association until he was in need of help. Financial support was decidedly necessary, but the personal interest of every member was equally necessary. Both Mr. Wallace and other speakers spoke very highly of the work accomplished during the past twenty years by the secretary, Mr. E. Pearson, the hon. secretary and other officials of the Association.

Mr. C. P. Pearson, who was very heartily and [illegible] received when he rose to speak, [illegible] approval of the principle of the [illegible] but it was rather cumbersome [illegible] and energy might be wasted [illegible] matters filtered through from [illegible] committees to the Central and Executive [illegible]. He suggested dropping the [illegible] Association started [illegible] was now 670; there [illegible] 2,000. The time had come [illegible] and he could not give the [illegible] to hoped the new scheme would be successful, so that the efforts of the past year [illegible].

When the president put the resolution to the meeting the principle of the scheme was carried without dissent. Mr. E. J. Deal considered £1,000 necessary for propaganda work, and asked for promises of donations. Eleven members promised £10 each, 15 promised £2, and five promised 2 guineas each, which, with the chairman's promise of £21, made a total of £216 10s. It was a pity Mr. Deal did not ask for donations to a guarantee fund, as he had raised the enthusiasm of the members. It is obvious that if, as Mr. Wallace suggested, a capable secretary was needed at a salary of £500 a year, a considerable guarantee fund will have to be raised to carry on until large numbers of members are enrolled. With London offices, clerical staff, travelling expenses, expenses of meetings, stationery and printing, a guarantee fund of from £1,000 to £1,500 appears to be necessary, because in the year just ended the H.T.A. subscriptions only came to just under £400, and, necessarily, some time will elapse ere subscriptions will balance the proposed expenditure.

The meeting left the consideration of details, preparation of rules, and selection of a secretary, subject to approval by the Executive Committee, to a committee composed of Messrs. E. Jackman, E. J. Deal, E. A. Bunyard, Finnegan, Cuthbertson, C. Page, G. W. Leak, Evans, R. Wallace, J. Cheal, Baker, E. Horton, Staymaker, Weeks, J. Harrison, junr., C. P. Pearson, A. Watkins and H. Morgan Veitch. Meanwhile the present officers and Council will conduct the business of the Association until the new scheme is brought into being.

A vote of thanks to Mr. Alfred Watkins closed the proceedings.

SEED BEANS AND PEAS.

By the Farm Peas and Pulse Requisition Amendment Order Beans and Peas imported for seed are exempted from the Requisitioning Order of 1917. Certain particulars are required to be furnished to the Food Controller, and the Beans and Peas must be passed by him as suitable for seed purposes.

TESTING OF SEEDS ORDER, 1918."

Although, under the "Grain Prices Order, 1918," which came into force on the 2nd inst., the prices of Wheat, Rye, Oats and Barley are fixed, there is an express provision to the effect that the Order is not to apply to any Grain which is suitable for seed, and which is also sold specifically for seed, in compliance with the provisions of the "Testing of Seeds Order, 1918." No grain so sold is to be used for any other purpose, and the buyer of any grain so sold (except when he is a person buying the grain for use as seed on his own establishment) must hand to the seller at the time of sale a declaration signed by him to the effect that he will resell the grain specifically as and for the purpose of seed.

The Order also prohibits the sale of grain otherwise than by weight, as well as the forcing or bleaching of grain.

Answers to Correspondents

AURICULAS: *C. F. P.* September is generally a good time in which to divide garden Auriculas, but if your northern garden is in a cold situation it would be well to do this work a fortnight or so earlier on future occasions. It is usual to divide pot-grown plants at about the end of May or during June, in order to allow the maximum time for them to become re-established before the next flowering season. In your light soil it would be well to add good turfy loam and to give a light dressing of slaked lime to counteract the heavy dressing of stable manure. Plant firmly and keep the crowns of the plants high when planting to prevent damping-off during the winter. After the planting is done keep the plants well supplied with water until rain falls

BOWLING-GREEN IN AN UNSATISFACTORY CONDITION: *W. A. J.* If the sample of turf submitted is typical of the bare patches on your green then there is a marked absence of lime in the upper portion of the soil. This fact would readily account for the grass dying off in the manner you describe. We would advise you to have the affected parts immediately forked over and dressed with builder's ground lime at the rate of 8 ozs. to the square yard and the remainder of the green treated with unslacked lime, using about 4 ozs. to the square yard now and a like dressing applied again in February. It would be futile to sow seeds until the spring, by which time the caustic effects of the lime will have passed off. By sowing thickly in early spring and by giving special attention to the green it may be possible to permit of playing on it by June. While this method will deprive the public of about a month's play, sowing is preferable, in these days of scarcity of labour, to turfing

CARNATIONS: *C. F. P.* The border Carnation generally thrives in ordinary good garden soil, but as your ground is rather light it will be well to incorporate a good proportion of fibrous loam and to also add either slaked lime or finely sifted mortar rubble. Plant very firmly and do not allow the plants to suffer from lack of moisture. October and March are the best months for planting; unless the situation is very damp the former is the best time, as the young plants become well established before their flowering season. But in cold, wet soils it is generally necessary to winter pot plants in frames and plant them out-of doors in March. To have a succession of first class blooms it is necessary to raise young plants by layering at least every other year. The layers should be pegged down as soon as the flowering season is over. A good selection of standard varieties includes Bookham White; Basuto, crimson; Brigadier, scarlet; Mrs. Elliott Douglas, yellow; Duchess of Wellington, lavender; Ellen Douglas, silvery grey; Fuyuyama, red; Elizabeth Shiffner, orange; Greyhound, heliotrope; Innocence, blush pink; Mrs. Robert Gordon, pink; Rosy Morn, rose-pink; Miss Willmott, coral-pink; Mrs. Andrew Brotherstone, purple and white; Mrs. A. J. Keen, yellow edged with rose; Montrose, white marked with scarlet; Zulu, dark maroon; and Purple Emperor

CATERPILLARS ON COPPER BEECH: *J. A.* The caterpillars are those of the Buff Tip Moth, which is always very common in this country

COLOURED POTATOS: *R. P. and N. D.* The specimens sent are self-coloured sports from King Edward. Such sports are fairly common, and will remain fairly true when propagated, but they show no advance either in cropping capacity or in quality on King Edward.

CREOSOTE AS A CURE FOR MILDEW: *W. P. N.* We have submitted your query to Mr. C. E. Bridgett, who has replied as follows: "While the vines are dormant, prune and rub off the rough bark. Mix clay with creosote until the mixture is of a paint-like consistency, and then apply it with a paint-brush to rods and spurs, taking particular care to fill up all crevices but not to paint the buds. My experiment was carried out last winter on Muscat of Alexandria and Black Hamburgh vines only, so that it is quite possible other varieties may not stand the treatment. I note *Market Grower's* appreciation of creosote as a cure for American Blight on Apple trees, but would state that it is only applied to the old wood, as it will kill green wood, therefore I find it best to cut away and burn all badly infested young shoots."

FRUIT AND VEGETABLE FARMING ABROAD: *Columbus.* Full particulars of the conditions which obtain may be had from the Agents-General of the countries referred to. There will be good openings for market gardening, especially fruit cultivation, in many countries after the war, but experience and capital are necessary, and the former can only be obtained by residence in the country you elect to start business in. Apply for information to the Consul General, Argentina, 601, Salisbury House, E.C.; the United States Consul-General, 42, New Broad Street, E.C.; and to the Agent General for British Columbia, 1, Regent Street, S.W.

NAMES OF FRUITS: *T. B.* Apple Handbling's Seedling.—*J. D.* Apple Early Nonpareil (syn Hicks' Fancy).—*J. P. and Co.* Apple Washington.

NAMES OF PLANTS: *J. Potts.* Artemisia vulgaris (Mugwort). It is sometimes grown in gardens.—*T. Brockbank.* 1, Leaves of a species of Salvia (not recognised); 2, Borago officinalis (Borage).—*L. S. Ilmenauth.* 1, Sidalcea spicata; 2, Chenopodium polyspermum var. cymosum; 3, Rumex crispus; 4, Verbesina encelioides; 5, Aethusa Cynapium.—*T. J. C.* Rubus phoenicolasius (Japanese Wineberry).—*G. B.* 1, Pyrus rotundifolia; 2, Crataegus Crus-galli var. pyracanthifolia; 3, Crataegus mollis; 4, C. melanocarpa; 5, Calluna vulgaris purpurea.

ONIONS DISEASED: *G. F.* The Onions are suffering from an aggravated attack of Onion Mildew, caused by the fungus Peronospora Schleideniana. Collect and burn all diseased plants, and scatter over the remaining healthy ones a mixture of powdered quicklime and sulphur, in the proportion of one part of lime to two of sulphur.

OVERGROWN FRUIT TREES AGAINST A FENCE: *G. E. T.* Plum and Cherry trees which have received no attention during the past two or three years are not easily brought under control and limited to the fence-space provided. Severe pruning would mean the removal of a large amount of the growth above the top of the fence and this would encourage further growth at the expense of fruit production. If it is possible to do so remove the branches from the fence and lift and replant the trees directly the leaves show autumnal colouring. A little root pruning may be desirable. Lime rubble and some fresh soil should be provided, and the whole made very firm about the roots. Everything should be made ready, so that replanting, on the same site, may immediately follow lifting. Give a thorough watering. Tie up the branches loosely to prevent damage by wind, and syringe them on warm days so long as the leaves remain. Later on, when the soil and trees have settled again, rearrange the branches and nail or tie in all that room can be found for. Do not be afraid to head the branches and endeavour to furnish the whole of the fence. Remove all awkwardly placed shoots as the work proceeds, and, if necessary, cut some of the branches back to the base of the tree.

PREPARING HOME-GROWN TOBACCO FOR SMOKING: *H. B.* It is usual to harvest Tobacco as soon as the leaves are ripe, commencing with the lower leaves, which are always the first to arrive at proper condition. "Ripeness" is indicated by loss of smoothness and gloss, by increase of substance and brittleness, by change in colour, by curling of the edges and the drooping of the leaves. Gather the leaves as they ripen and string them back to back, on thin twine. Deal separately with the leaves harvested at each gathering and hang them in a shed where ventilation can be controlled and artificial heat provided if necessary. Probably a greenhouse could be so adapted as to serve as a drying shed. The curing of the best pipe Tobacco is a somewhat complicated process, as atmospheric moisture must be controlled as curing proceeds. Full particulars of the cultivation, harvesting, and curing of Tobacco, as practised in Ireland, may be obtained from leaflets published by the Department of Agriculture for Ireland, Upper Merrion Street, Dublin, and sent post free on application

PRICES FOR HOME-GROWN ONIONS: *H. J. B.* So far as we are aware the Order fixing the prices for home-grown Onions, as published in *Gard. Chron.*, April 20, 1918, has not been rescinded. We understand, however, that a new Order on the subject will shortly be issued by the Food Production Department.

PRUNING CLEMATIS: *Dun.* Clematis belonging to the Jackmanii and Flammula groups, and also some of the lanuginosa forms, may be pruned severely in late winter or very early spring, some time before new growth commences. Unless a specimen has become excessively crowded with growth it is not desirable to cut back the whole of the growths. A better plan is to cut a proportion of the stems well back, and thin out the remaining growths.

ROOT PRUNING TRAINED FRUIT TREES: *A. F. B.* Take out a trench 2 feet from the stems of the trees, and all along one side of the row. Remove the soil with a fork so as not to damage fibrous roots unnecessarily. Cut back strong roots and bring the finer roots nearer the surface. Work underneath the root system and sever strong, downward-growing roots. Add a little lime rubble when filling up the trench and ram the soil firmly. With reference to double digging or trenching in the kitchen garden where there are standard Apple trees, it will be almost useless to trench nearer than 6 feet from the stems, because vegetable crops will not succeed under the spreading branches of the trees.

SUGAR FROM SUGAR BEET: *W. L.* Clean and boil the Beet until well cooked, then rub the skin off and cut the roots into thin slices and chop finely. Put 2 pints of water into an enamelled saucepan and bring it to the boil, then add 2 lbs. of the chopped, cooked Beet and boil with the lid on for three-quarters of an hour. Press the whole through a fine sieve and then strain it through a cloth. Put the strained juice into a clean saucepan, bring to the boil again, and add half a teaspoonful of bicarbonate of potash. Keep the juice boiling until it is reduced to one-third, then pour it into a hot bottle and cork tightly at once. There should be about 6 ozs. of sugary syrup.

USEFULNESS OF CYDONIA FRUITS: *Solopian.* The fruits of Cydonia (Pyrus) japonica may be used for jelly-making in the same way as the fruits of the common Quince. Fruits of Cydonia Maulei may also be used for the same purpose.

VEGETABLES FOR GROWING IN A CONSERVATORY: *G. M. S.* Tomatos may be grown in the conservatory during the winter, but their cultivation is hardly a profitable business, having regard to the fuel necessary to maintain the requisite temperature. If salad plants are in demand, a regular succession of Mustard and Cress could be grown, and Cos Lettuces, raised thickly in boxes and cut while quite young, would serve in the absence of larger examples. Under the plant stages or in a darkened part of the house Rhubarb and Seakale could be forced easily. If not too lofty the conservatory would be a very suitable place in which to raise vegetable seedlings early in the New Year for the purpose of securing sturdy plants for setting out of-doors as soon as the condition of the weather permits.

THE CONTROL OF ROSE DISEASES.

IN recent years vast improvement has taken place in the colour and form of the Rose and its freedom and continuity in flowering. The flowering period, which formerly ended in July, has, through the efforts of the hybridiser, been extended to late autumn, and in mild seasons to Christmas. This is a great gain, and has given to the Rose a first place among hardy English flowers. But the gain has been accompanied by a serious increase in the destructive character of fungous diseases among the plants. Mildew makes the loveliest foliage unsightly, weakens the plants, and spoils the flowers. Black Spot defoliates the stems in late summer, and ruins the autumn flowering, while crown canker—a comparatively new disease—will in a few years destroy the plants altogether.

It is not so much that Roses are more susceptible to disease than was formerly the case; in fact, I think the contrary is more likely to be true, for many of the older Roses were prone to be affected by disease if it came their way. John Hopper and Baroness Rothschild will fall victims to mildew as readily as Killarney, while we have a few modern Roses nearly mildew proof. It is rather that the great increase in the number of Roses grown has provided more hosts for the diseases and enabled them to spread more generally.

This being the case, efficient and ready methods of controlling and combating diseases have become almost as essential to the continued popularity of the flower as improvement in its form and habit. This has been specially impressed on the rosarian by the difficulties he has met with during a four years' war, when labour has become increasingly scarce, and he has had many other matters on hand to distract his attention from Rose growing.

Hitherto the methods chiefly relied on to control disease have been spraying the plants with some fungicide, such as cyllin or carbolic soap, or proprietary specifics such as Abol and Vek. It was soon recognised that these methods were preventive rather than curative, that to be even moderately successful spraying had to be repeated at intervals of ten days or so, and, moreover, to be done with a certain amount of skill, while in wet weather the protection afforded was of the slightest. Lime sulphur and Bordeaux mixture are more satisfactory in one sense, namely, that they adhere longer to the foliage and are less easily neutralised by rain, but they have the great disadvantage that they quite spoil the appearance of the foliage, Bordeaux mixture covering the leaves with a fine, bluish-green dust, while lime sulphur leaves a number of small white spots completely covering the foliage and impairing its beauty.

In the circumstances, an article by Dr. L. M. Massey, Plant Pathologist, Ithaca, N.Y., contained in the *American Rose Annual*, the third number of which has recently been distributed, becomes of more than ordinary interest. Dr. Massey has for the past two years been conducting an investigation into diseases of the Rose, both by inquiry among a large number of Rose growers and by careful experiment. About 600 Rose plants are being grown under experimental conditions in the greenhouses of Cornell University, and Dr. Massey is not only experimenting in the control of the better-known diseases, but is also investigating new diseases, while life-history studies of several fungi are in progress. He considers that the results to date are all that could be expected, and are very encouraging.

In the article before me he deals with crown canker, black spot, and mildew. Plants suffering from crown canker disease are affected at the crown, usually just at the surface of the soil, the definitely diseased region extending several inches above the ground. The union of scion and stock and the area immediately above it are the most common points of attack. Affected plants do not die quickly, but linger on, and yield progressively poorer and fewer blossoms. Moisture plays an important rôle in the severity of the disease, and inoculations made several inches above the soil frequently made no progress unless kept moist by being surrounded by wet cotton. This seems to have led one grower to adopt a system of planting whereby the graft union is above the soil, with the object of preventing infection at that point, and he also removes the soil from about the crown to secure a dry condition at that susceptible part. Dr. Massey, however, considers these methods objectionable. He has as yet obtained no definite results in the control of the disease, and thinks the control may resolve itself into some method of soil sterilisation. The fungus grows well in both acid and alkaline media, so that the possibility of control by developing an acid or alkaline condition of the soil does not appear to be promising. From the progress of his experiments he hopes to be able to offer growers definite advice in the near future.

With the control of black spot and mildew he has been more successful, and considers that a sulphur arsenate dust mixture is an efficient control, amounting almost to a specific.

Experiments were carried out in the Nursery and also in the Test Garden of the American Rose Society at Ithaca, N.Y., various sprays and powders being used, including sulphur arsenate (a mixture of 90 parts sulphur with 10 parts arsenate of lead, applied as a dust), Bordeaux mixture, ammoniacal copper carbonate, and lime sulphur. The treatment was applied at the end of May, and twice in each of the three succeeding months. For black spot, sulphur arsenate, Bordeaux mixture, and lime sulphur were found to be efficient fungicides, ammoniacal copper carbonate being less satisfactory. On the contrary, in the case of mildew the bushes treated with sulphur arsenate were found practically free from this disease, which developed severely on those sprayed with lime sulphur and Bordeaux mixture.

Dr. Massey therefore considers the sulphur arsenate dust not only superior in fungicidal qualities, but less liable to render the plants unsightly than Bordeaux mixture or lime sulphur. The article gives careful details of the experiments, and should be consulted by those interested in the subject.

Sulphur has been long used in this country as a fungicide, and, under glass, where there is no wind and conditions of moisture can be regulated, and, moreover, it can be dusted over the hot water pipes, it is practically a specific and efficient control of fungous disease.

A certain amount of warmth, however, seems to be essential for its maximum value, and, used alone, it is comparatively of less efficiency in windy and rainy weather. It remains to be seen whether in combination with arsenate of lead it is of more value than when used alone under these conditions.

The best time for its application seems to be early morning during spells of hot, sunny, and still weather, while the dew is still on the plants.—*White Rose.*

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM CENTAUR.

A PRETTY and graceful hybrid not previously recorded, obtained by crossing Odontoglossum Edwardii and O. harvengtense (crispum × triumphans), named Centaur, is now flowering in two varieties in the gardens of Mrs. Bischoffsheim, The Warren House, Stanmore, Middlesex. The plants bear the long, branched spikes of O. Edwardii, and in size and colour the flowers approach nearest to that species, but the form of the lip and its crest bear distinct evidence of O. triumphans. In their early stage the flowers, which are about 2 inches in width, are deep claret-purple with lighter colour in the margins and tips. When mature they assume a

gold bronze tint, showing the yellow and brown of O. triumphans as a ground-colour.

CATTLEYA SYBIL VARIETIES

IN *Gard. Chron.*, August 21, 1915, p. 119, illustrations were given showing remarkable variation in forms of Cattleya Sybil (Dowiana aurea × rubrescens), one of the plants illustrated having the form of C. bicolor, with its narrow, elongated lip, and the other the shape of C. Eldorado, the lip having a tubular base with ample expanded front as in C. Eldorado, the reversions being to the two species which were the parents of C. iridescens.

Plants of a small batch, several of which have flowered in Mrs. Bischoffsheim's gardens, The Warren House, Stanmore, give similar evidence of dissimilarity. So far as they have been proved, those of the type nearest to C. bicolor are the most frequent, but one in flower at the present time of the C. Eldorado type closely resembles the variety rotunda bella in the illustration mentioned. The fragrant flowers are light yellow: the labellum has a mauve-coloured front, orange disc, and gold lines at the base.

at the roots for several days afterwards: overhead sprayings twice daily will suffice for a time, but much depends in this respect on the climatic conditions. The soil must never be allowed to get really dry nor be unduly saturated. For several weeks after the final potting water should be applied overhead through a coarse rose can, but after the middle of October this method would destroy the flower buds, and should be discontinued. Indeed, to be quite safe, overhead watering and spraying should cease after the third week in September. From that time onward extra care is necessary in applying water to the roots. Not the slightest trace of moisture should be allowed to reach the base of the flower-stems, for the least carelessness with the water-pot will kill the flower-buds. If the corms are placed high in the pot at the final potting the chance of water getting amongst the buds will be lessened.

While not a gross feeder, the florist's Cyclamen, nevertheless, is greatly benefited by judicious feeding. As soon as the flowering pots are well filled with roots, weak doses of clear soot-water should be given twice a week, to be followed after two or three weeks with weak

FLORISTS' FLOWERS.

CYCLAMEN LATIFOLIUM.

I READ and re-read with very great pleasure the interesting and instructive article on "Cultivation of Cyclamens," by Mr. J. W. Forsyth, in the issues for July 20 and 27. I have taken more than ordinary interest in these fine plants for the last quarter of a century, and, like many others, had but indifferent success at first. For the past fifteen years, however, I have been very successful, and each season have a good batch of these superb winter and early spring flowers.

Mr. Forsyth did not deal with watering, overhead syringing, feeding, and insect pests, and the following remarks on these subjects may be useful to growers.

As the soil at the final potting should be of a fairly substantial nature, unless watering is done very carefully, the compost will be liable to become sour, resulting in a serious check to the plants. As soon as potting is finished the plants should be watered thoroughly once to settle the soil, and moisture should not be given liquid manure made from sheep or cattle droppings, and this stimulant also should be applied about twice a week. Ichthemic guano is a good food for Cyclamens. Commence with a dessertspoonful to 1 gallon of water once a week, and later use a tablespoonful twice a week. It is desirable to vary the food, and these three stimulants may, with advantage, be given in alternate weeks.

When grown in proper conditions the Cyclamen is not unduly troubled with insect pests, but where the accommodation for growing the plants is not entirely suitable, green fly, thrip, red spider, and mite often attack the leaves and flowers. If the pit or house in which the plants are growing be vaporised once every three weeks it is a fairly easy matter to keep the plants clean. This specific is also a certain cure for green fly, if present. But where the other pests mentioned are present spraying with a solution of XL All liquid insecticide, at fairly frequent intervals, is useful, while for bad attacks dipping the plants in a 20-to-1 solution of the same specific will be effectual. At this strength it is certain to destroy the insects, but dipping should be repeated in three days, and finally again three days later. *C. Blair, Preston House Gardens, Linlithgow, Scotland.*

TOMATO BIDE'S RECRUIT.

THIS Tomato is proving itself as valuable for cultivation in the open as under glass. The illustration in fig. 57 shows plants growing here against a wall with an eastern aspect. The plants are 5 feet high and bearing profusely; some of the trusses are carrying twenty fruits each. The fruits are of medium size, smooth, bright red in colour, and the flavour is of the best. *E. Molyneux, Swanmore Park Farm, Bishop's Waltham, Hampshire.*

LETTERS FROM SOLDIER-GARDENERS.

NOTES FROM EGYPT.

IN the future the Sinai Peninsula may be more frequented by visitors than hitherto, because the difficulties of travel overland between Egypt and Palestine will be removed by the railway which now links the two countries and is the means of redeeming the rich plains of South Palestine from the decadence into which they have sunk.

A few miles east of the Suez Canal the large Oasis of Katia is most refreshing and restful, with its many acres of Date Palms, set amid a desolate region of undulating sand. The Palms are of large size, and each yields a bountiful crop of fruits. At the time I was there (not by personal choice) the fruits were ripening, and I noticed some trees bore deep golden-yellow Dates, while the majority carried those of the characteristic brown colour.

On the outskirts of the Katia Oasis there were newly planted trees in various stages of growth. The procedure is to make a rather wide trench by removing the loose sand to a depth of about 18 inches or 2 feet. A moist planting medium is thus found for the young trees. The leaves are drawn together at planting-time by means of a wisp of the coarse grass that grows sparsely in clumps near the groves: this is for the purpose of minimising the harmful effect of wind and sun. I imagine planting is done at about the time the fruits are gathered from the old trees, consequently the young trees become established before the return of the hot months.

Near the old-time frontier at El Arish there is another considerable area of Date groves, as well as large tracts of land under Fig trees. Some of the latter are of considerable size and planted at regular intervals, without the least indication of overcrowding. After a young tree is established no further attention appears to be needed. Although it never rains here during the long hot season, the trees perfect their crops and do not suffer to any extent from drought. It is a most remarkable thing that the sand is moist below the loose surface, and water is invariably found at very little depth in this part of the desert.

Caryopteris Mastacanthus is in flower in many gardens, and it deserves to be included where a collection of flowering shrubs forms a feature for the embellishment of the grounds. The flowers are blue, and borne on the terminals of the current year's growth. The cultural requirements of this plant are not exacting, neither is it particular as to position, provided that it is not planted under trees or allowed to be overgrown by more robust neighbours. On the sides of some of the wadis in Palestine this plant grows wild, forming fair-sized shrubs. With it Arundo Donax flourishes abundantly. I have not seen this grass grown successfully in Great Britain. Although I have seen its cultivation attempted in the south, the results did not produce a true indication of the plant's characteristic proportions. *F. Gooch, Palestine, August 10, 1918.*

FOREIGN CORRESPONDENCE.

THE BARCELONA EXHIBITION.

IN response to an enquiry as to the progress, from a horticultural point of view, of the great exhibition to be held at Barcelona after the war, we have received the following interesting letter from Monsieur J. C. N. Forestier, director of the horticultural section, who is best known to readers of the *Gardeners' Chronicle* as the *Conservateur* of the beautiful promenades of Paris, including the Bois :—

"The Barcelona Exhibition will include an International section, and a section exclusively Spanish.

"It was first planned to take place at no specific date, but to be opened a year after the cessation of the war. Work was begun in 1914, and pursued with activity, so as to be quite ready as soon as circumstances permitted the organisers to announce the date of opening. The site chosen comprises the whole of the northern slope of the mountain of Montjuich. A short time ago this mountain, situated between Barcelona and the sea, crowned by the famous citadel which commands the town and the port, was very difficult of access, there being no carriage way, and the place being separated from the town by a very poor quarter. The aim of the official Commission of the Exhibition (which is collaborating for the purpose with the town authorities and the Government) is to utilise the site firstly for the purposes of the Exhibition, and afterwards to make it form part of a scheme of permanent gardens and pleasure walks.

"The Commission has made a point of undertaking first the preparation of the roads leading to the mountain, and of the gardens which will at first be the gardens of the exhibition, and afterwards the public gardens of the town.

"The chief difficulty in the task which lies before us is the impossibility of forming beforehand a simple plan of construction for the scheme. One is under the necessity of uniting a number of small details into a complete whole which shall be not merely a collection of small gardens, but a homogeneous exhibition. Besides this, a great part of the ground chosen for the site is merely lent to the Exhibition authorities, and will have to be returned to the various owners after the Exhibition has been held. I have therefore adopted the plan of utilising the site at my disposal (which is very varied) to form a number of gardens of different kinds, which are united either by avenues of trees, or by paths from the one to the other, where they lie close together.

"I do not think it is part of the scheme to hold an International Horticultural Exhibition, but the love which is gradually developing in Spain for everything connected with flowers and gardens may lead to a modification of the original plans in this respect.

"The climate of Barcelona is almost exactly that of Nice, but the slope of Montjuich which has been chosen as the site of the Exhibition turns its back to the sea, and is exposed to the north wind. It is composed of solid rock, in which are hollowed out the crevices on which practically the whole town is built, and which contain, however, a considerable depth of very good soil. The flattest portions have the reputation of producing the best Wheat in the country."

BULB GARDEN.

LILIUM SULPHUREUM AND L. NEPALENSE.

MENTION of this grand Lily by Mr. Watson in his 'Notes from Kew,' p. 55, serves to carry one's memory back nearly thirty years. To be exact, it was first publicly shown, by Messrs. Low, then of Clapton, at the meeting of the Royal Horticultural Society, on June 27, 1889, when, as Lilium Wallichianum superbum it was awarded a First-class Certificate by the Floral Committee. A good deal of controversy arose over the name, the plant being generally regarded as distinct from L. Wallichianum, in bulb, habit, and flower, as to entitle it to specific rank. The name of L. Wallichianum superbum was given to it by Mr. Baker, but after a time that authority revoked his previous decision, and named it L. sulphureum, a name it still bears.

At the time of its introduction Messrs. Low stated that the bulbs came from a considerable elevation on the hills in Burma, where the climate was quite temperate. It has proved to be the most robust of the Burmese Lilies, though hardy only in particularly favourable districts in this country. Its late season of blooming militates against its use out of doors. The bulb is large, firm, and of a reddish-brown tint, while the stem is thickly clothed with narrow, pointed leaves, which gradually become broader towards the top of the stem. The flower is fully described by Mr. Watson in his article referred to. A notable feature of this Lily is the presence of a number of small bulbils in the axils of the leaves, which afford a ready means of propagation.

I have often found that bulbs of L. sulphureum are late in starting into growth, but when the stem makes its appearance it grows rapidly.

Somewhat less than a year previously, namely, on September 11, 1888, Messrs. Low had flowered another Lily, around which great interest was centred. This was Lilium nepalense, a species concerning which there were many and diverse opinions. It is said to have first flowered in this country in 1855, but it is quite feasible if it was the true species, such as we have frequently seen within recent years. The stock has been to a great extent kept up by importations, as the plant does not readily conform to culture in this country. Still, imported bulbs as a rule flower well the first season. L. nepalense is essentially a greenhouse species, and is wanting in the robust constitution of L. sulphureum. It is, however, such a distinct Lily as to well repay extra trouble in cultivation. The flowers, which are regularly curved, are, in the centre, of a rich purple colour, while the upper part of the segments are yellowish green or greenish yellow. The depth of the purple colouring and the amount of the flower covered by it is also very variable. As stated by Mr. Watson, some of the finer Burmese Lilies have disappeared, and in these circumstances the same fate will in all probability befall L. nepalense. *W. T.*

A NEW HYBRID LILY.

A NEW hybrid Lilium (see fig. 30), which flowered for the first time in 1917, was shown before the Floral Committee of the Royal Horticultural Society on August 27, 1918, and received an Award of Merit together with the name of Lilium Parkmannii Hayward's variety.

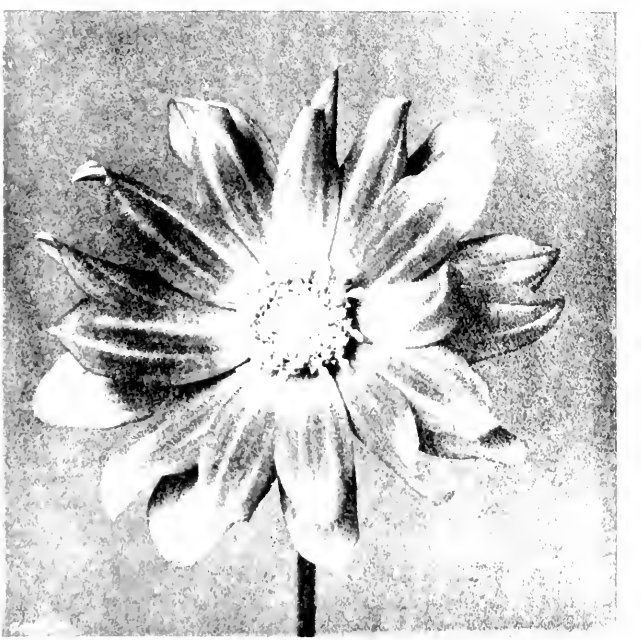

FIG. 30.—PARKMANN'S SOUTHERN STAR.—COLOUR SCARLET, STREAKED WITH YELLOW, AND SHADING TO PINK AT THE TIPS OF THE SEGMENTS. (R.H.S. Award of Merit and N.B.S. First-class Certificate, August 27, 1918.)

(See p. 110.)

The production of a first-class hybrid between the two fine and spectacular groups of Lilies is a notable event, and the long lapse of time between the arrival of L. Parkmannii and the flowering of the newcomer makes the new hybrid doubly welcome.

As the raiser of the latter I regret that L. Parkmannii did not exist in cultivation long enough to gladden the eyes of latter-day Lily-lovers—myself among them. I have had many chats with growers of the older generation, who can remember L. Parkmannii when it was at its best, and some of these who saw the new Lily after the meeting of August 27 asserted that it was not L. Parkmannii. Mr. Perry, of Enfield, whose interest in Lilies no one will dispute, has seen the new hybrid, and is certain that it is not L. Parkmannii, as it differs from the latter in form, petal, and in colour. Mr. Perry, who has had access to the wonderful collection of Lily paintings of Dr. Reed, of

Petrograd, gave me a detailed account of the differences between the two Lilies.

I do not wish to question the decision of the R.H.S. Floral Committee, but I should certainly like to see the whole question of nomenclature cleared up. The new Lily can hardly be a variety of L. Parkmannii, as the latter disappeared from gardens long before the coming of the present Lily, and of course took no part in its production. Further, Mr Parkmann's account of his hybrid gives L. auratum as one parent, whereas in the present hybrid L. aura-

The Week's Work.

THE KITCHEN GARDEN.

By E. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Celery.—Take advantage of dry days to place a few inches of soil round the stems of early Celery. It is a mistake to add much soil at one time or long before the plant has completed its growth. Early Celery may be easily blanched by binding the stems with thick brown paper or the special collars sold for the purpose. Tie the stems carefully together with soft binding material before placing the soil close to the plants, and remove the ties when the earthing up is completed. In dry weather waterings are necessary; it is almost impossible to overdo the watering of Celery, but moisture should always be given before soil is added to the plants. Break up the soil finely before using it for earthing-up and dust it freely with soot to check both slugs and worms.

Carrots.—Where early sown, stump-rooted Carrots are still in the ground the roots should now be lifted and stored in a cool spot or in pits. Roots that remain in the ground after this date become hard and dry and of little value. Thin out late Carrots sown in frames to 3 inches apart and keep the soil clear of weeds.

Cabbages.—Transplant August-sown Cabbages as soon as they are large enough for transference; small plants do not receive so great a check in transplanting as large specimens. Early, small-hearted sorts, such as Harbinger, may be planted 15 inches apart and such kinds as Flower of Spring 18 inches apart each way.

Turnips.—The roots should be thinned to 4 or 6 inches apart and the rows dusted with soot at short intervals. Draw each alternate plant for use as required, leaving the others to remain for winter use. Hoe the ground on frequent occasions to encourage a quick growth.

Leeks.—Pay extra attention to this most important crop, which serves as a substitute for Onions when the latter are scarce. Keep the ground between the rows frequently stirred and the roots well supplied with water and weak liquid manure.

Winter Spinach.—Spinach raised from seed sown as advised last month should be encouraged to grow freely. Extra attention is necessary where the soil is of a heavy nature, or the plants may soon be destroyed by slugs. Dust soot and lime amongst the plants and frequently stir the soil. Only on warm borders where the soil is light and rich should Spinach seed be sown after this date.

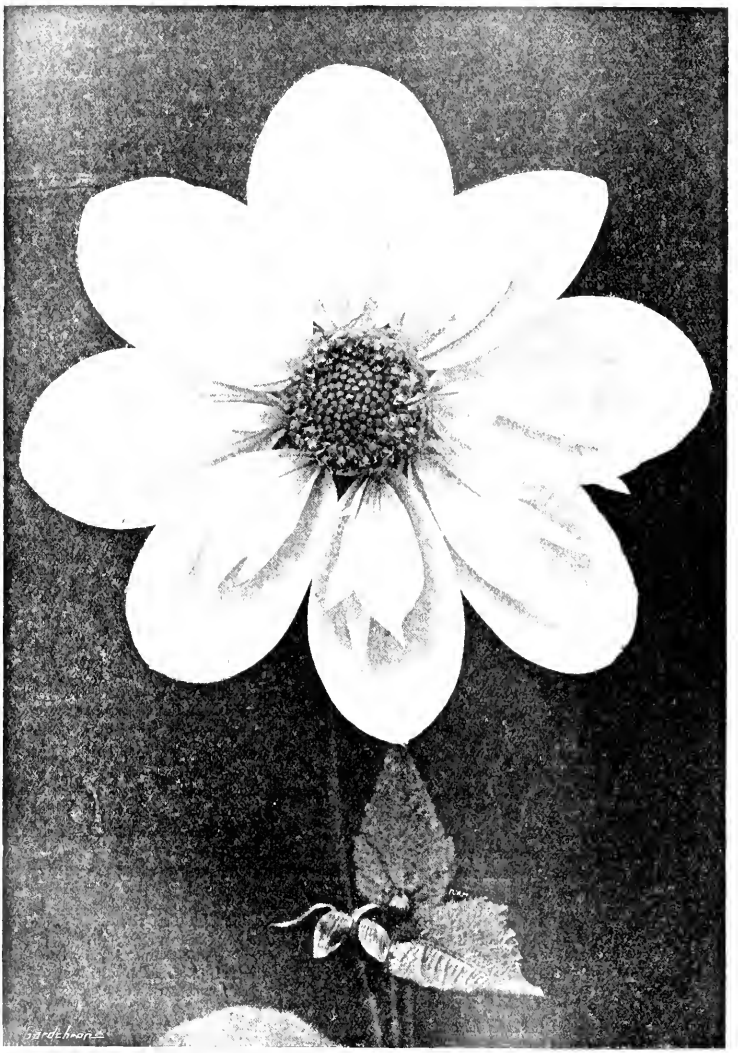

FIG. 58.—A GOOD TYPE OF COLLERETTE DAHLIA (Georgina, a pale lemon-yellow variety.)

tum . . . Hyde was the parent a very different . . . to the typical L. auratum.—P. S. *Hargreaves*, ...

[If a hybrid has been raised between two distinct species, and only named and recorded, any other hybrid raised by crossing a varietal form of one of the same species with either the type or a varietal form of the other species, becomes a variety of the original hybrid, even though the latter has become lost to cultivation in the meantime.—EDS.]

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Calanthe.—Deciduous Calanthes are in full growth and forming new pseudo-bulbs. If they are healthy, well-rooted specimens the roots will require more water at this season than at any other time of the year. It is important that the plants should be exposed to as much light as possible, without permitting them to be scorched by the sun. They should be placed near the roof-glass and whenever possible allowed plenty of fresh air.

Masdevallia.—The best months for repotting or top dressing the majority of Masdevallias are the beginning of September and February. The present time is preferable, as the roots are more active during September and October than at any other season, and, in addition, the weather conditions are cool and moist, therefore favouring a quick re-establishment of the plants. New leaves are developing and new roots will soon be produced; the latter will quickly grow into the fresh compost and be well established before winter. Healthy plants that have outgrown their rooting space, with compost in good condition, may be turned out of their pots and placed into larger receptacles with as little root disturbance as possible. Large, overgrown specimens that have become bare in their centres may be divided, and the best portions potted separately into the smallest-sized pots that will accommodate them. The smallest pieces may be placed several together in small pots, and, by next February, they should be in a suitable condition for transference to larger receptacles. Others that have sufficient rooting space for another season's growth, will, provided the compost is in good condition, not require repotting, but some of the soil may be removed from between the surface roots and fresh material substituted for it. Previously to repotting the plants it is advisable to withhold water for a few days, for the drier the roots the less liable are they to be injured. Masdevallias of the stronger-growing kind are vigorous rooting plants, requiring plenty of rooting space, and they are best grown in pots or deep pans. They include M. Veitchiana, M. ignea, M. Lindenii, M. Gargantua, M. Mooreana, M. macrura, and the numerous members of the Harryana type. Others that are not of such vigorous habit include M. Courtauldiana, M. Chelsonii and M. Stella. All those mentioned above may be grown on the plant-stage near to

the roof-glass. The dwarf-growing kinds—M. Armini, M. Shuttleworthi, M. picturata, M. muscosa, M. O'Brieniana, M. tridactylites, and others of this section—should be placed in shallow pans and suspended from the roof-rafters. A suitable compost for Masdevallias is a mixture of half-decayed Oak-leaves that have been rubbed through a half-inch sieve, short pieces of A1 Fibre, and portions of Sphagnum-moss in equal proportions. Crushed crocks and coarse silver sand should be incorporated with the other materials. The pots should be two-thirds filled with clean crocks for drainage. Pot moderately firmly, keep the base of the leaves level with the rim, and carefully work the compost between the roots. Do not afford much water until the roots commence to grow into the new compost. Shade the plants for a time from bright sunshine, and maintain a moist atmosphere. Masdevallias delight in plenty of fresh air, but cold draughts should be prevented. If a special house is not available for these Orchids they may be grown in the warmest and shadiest part of the Odontoglossum house. The white M. tovarensis, the yellow-flowered M. Davisii, and those of the Chimaera section are best repotted in February, and may be kept in a slightly warmer house during the winter months than the others.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Gloriosa superba.—Gradually reduce the supply of water at the roots of Gloriosas to allow the plants a period of rest. When the foliage has died down place the plants underneath a stage in a cool house or in a dry, frost-proof shed. Turn the pots on their sides in order that the roots may be kept perfectly dry during the winter.

Fuchsia.—A fresh stock of Fuchsia plants should be raised annually from cuttings, which may be inserted now. There are plenty of young shoots on the old plants suitable for use as cuttings. These should be inserted in a sandy compost in 5 inch pots. Make the soil firm about the base of the cuttings. Thoroughly water the soil once and plunge the pots in a moderately warm hot-bed in a propagating case. Keep the cuttings shaded from bright sunshine until roots form, and afterwards grow them on steadily in a light glasshouse near the roof-glass in a temperature of about 50°.

Tulips.—As soon as the bulbs are to hand those which are to be grown in pots should be attended to at once. Use a rich compost and pot firmly. Plunge the pots containing the bulbs in a bed of ashes in the open until the shoots have grown an inch or two, then transfer them to a cold frame.

Narcissus. All kinds of bulbs, including Narcissi, should be well established in their pots before they can be forced successfully. The bulbs should be procured as soon as possible and placed in their flowering receptacles. Paper White, Trumpet Major, Golden Spur, Emperor, Sir Watkin, Madame de Graaff, Barrii conspicuus and Elvira are all suitable sorts for pot culture.

Housing Plants.—Suitable houses should be prepared for the wintering of Cyclamens, Primulas, Bouvardias, Pelargoniums, and Salvias. Low houses or heated pits are the most suitable for those plants. Let the glass be perfectly clean both inside and out, and grow the plants near the roof-glass.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

Gooseberries.—Sometimes old Gooseberry bushes may be rejuvenated by being cut hard back, but if marked decadence is manifest then it is a better plan to arrange for a new plantation. The new site should be on ground where bush fruits have not been grown for several years. Cordon-trained plants are very serviceable, as, when they are employed, more use may be made of any given area, and the picking of the fruit is rendered easier. In selecting Gooseberry bushes exercise every caution with respect to the Gooseberry mildew. An early inspection whilst the leaves are still fresh will be advisable in any case.

Currants.—With respect to Red and White Currants one needs, as in the case of all bush fruits, to choose them from a quarter in a nursery. I like to choose bushes with a slightly more pronounced stem than is, as a rule, obtainable. There should be, in my opinion, a clear foot of stem before any branches radiate from it. I also strongly advocate standard plants of Red and White Currants. Not only are these ornamental, but from a utilitarian standpoint they are most commendable, as they will provide a good supply for the latest pickings. Standards are easy to manage and quite easy to net securely. A clean stock of Black Currants is most desirable. A few years ago it was stated that Boskoop Giant was immune to attacks of Big Bud, but I have not found the statement to be true.

Cordons.—A great deal more use should be made of cordon-trained Gooseberries and Currants for clothing bare spaces on walls. These trees will thrive well on a northern aspect, and are not troublesome to manage. Double cordons are to be preferred.

The Raspberry and Allied Fruits.—It pays well to make new Raspberry plantations and burn the old stock. The new planting, however, should be done one year in advance in the case of summer-fruiting varieties, but autumn-fruiting varieties will yield a good crop the first autumn after planting and well within the year. To me it is a surprising fact that so few of these late-fruiting varieties are cultivated. Of the summer fruiters there is a good choice; Superlative does not thrive in every garden, but there are Hornet and Baumforth's Seedling from which to choose. When purchasing Raspberries make it a condition that they are well packed, so as to prevent the roots from suffering, and when received plant them at once. The Loganberry, the Newberry, and the Lowberry are all well worth growing, and they thrive in almost any garden.

FRUITS UNDER GLASS.

By W. J. GRISS, Gardener to Mrs. THOMPSON, Keele Hall, Newcastle, Staffordshire.

Cucumbers.—Where Cucumbers are required in winter, vigorous young plants should be set out at once in narrow ridges or small mounds of compost placed on stages. The use of fermenting material is advisable, therefore a good layer of leaves and stable litter in equal proportions should be placed in a ridge and made firm. Small cones of soil may then be placed for the reception of the plants, adding more of the compost as the roots require it. Stop the leading shoot when it has grown half-way up the trellis, and pinch all laterals at the first joint beyond the fruits.

Renovating Established Plum Trees.—Old, established Plum trees in borders, which are not giving satisfactory results, should be given attention directly the crop is gathered. The borders need to be renovated periodically, for if this is not done growth becomes stunted and the trees gradually die from exhaustion. In such cases the best method is partly or entirely to renew the borders during the next few weeks, as if the work is done early in the autumn the roots will become established again before winter. The best compost for Plum trees is tough, fibrous loam of a calcareous nature; if the soil is deficient in lime a good sprinkling of chalk or mortar rubble should be added. In renovating the borders take out a trench half way round the tree, and 3 feet from the main stem. Gradually remove the old soil with a fork, working towards the tree and taking care not to damage the fibrous roots. Whilst the latter are exposed they should be syringed occasionally or covered with damp mats. Afterwards, fill in the trench evenly and firmly, laying out the roots and fibres laterally towards the surface. Give one good watering to settle the soil, syringe the trees twice daily, and shade them lightly in bright weather until they commence to make new roots.

Young Plum Trees.—It frequently happens that young Plum trees grow too strongly after planting as to need root-pruning. The tree should be lifted and replanted, or a trench may be taken out half-way around the stem and roots cut which are growing downwards or outward.

Planting Plum Trees.—Where it is the intention to plant new trees no time should be lost in deciding a selection of suitable varieties and in placing the order to the nursery. Plums need a warm sunny site under glass, and where a choice of walls is available the walls should be furnished with standard, half-standard, or dwarf trees. Cordons may be trained up the rafters, and dwarf, fan-trained trees on the back wall. With judicious treatment the trees need to bear very heavy crops of fruit, far superior to those grown outside. The following varieties are suitable for growing under glass: Coe's Golden Drop, Jefferson, Kirke's, Dennistan's Superb, Early Transparent Gage, Green Gage, Reine Claude de Bavay, and Monarch. Culinary varieties include The Czar, Belgian Purple, Victoria, Early Prolific (Rivers'), Diamond, and Pond's Seedling. When planting use similar compost to that advised for Plums in borders.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

Double Dwarf Sweet William.—This very old crimson variety, which is a mule, forms very large masses in soil that agrees with it, while in that which it does not appreciate it is important to renew the stock regularly at yearly intervals. This plant, like many Pinks, roots along the stems, and should be propagated somewhat similarly to Pinks. I have sometimes kept up the vigour of decadent plants by means of a surface dressing of light soil spread all over the clumps about this time of year, and into which new roots find their way. On the whole, however, annual propagation is preferable, resulting, as it does, in stronger and more florriferous plants, old plants never being quite so brilliant as these.

Hyacinths. I have grown Hyacinths for many years, planted thickly, for the production of loose spikes for cutting, and on that account did not regard quality at all. Bulbs, however, which have been allowed plenty of space, demonstrate the possibility of, even in Scotland, producing fairly good spikes. Justice in the eighteenth century, advised the growing of Hyacinths in Scotland, but the type of that period would not be looked at now. I am trying some of the bulbs in pots. I advise very finely pulverised soil for what bulbs one may have, and surface-dressing them with superphosphate in the spring. Only such sorts as King of the Blues, L'Innocence (which does splendidly), Ida, Robert Steiger, and similar varieties should be attempted. I would not throw away off-sets, but plant those apart to make flowering specimens.

Delphinium.—Seedling Delphiniums are very useful at this time of year, as they give a tone to borders which no other plant provides. The present time is suitable for sowing seeds saved now or recently. A large number of seedlings may be raised in an ordinary box, if placed in a greenhouse or pit to induce rapid germination. When well through the soil the seedlings should be pricked out in other boxes filled with a light compost and afforded space sufficient for their development until they are potted into 4 inch pots before winter sets in. A compost of two parts turfy loam to one part leaf-mould, with a little sand added, is suitable, and if the plants are grown in a temperature of 45° to 50° a shift into 6 inch pots in January will carry them on until fit to be planted where they are to be flowered. Such plants should give splendid spikes, very much superior to those raised from seed sown in January or February of the year of flowering. I rather prefer the lighter shades of blue, which go better than dark blue with the other autumn flowers, but all are beautiful and none need be rejected.

EDITORIAL NOTICE.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER, *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 57.09.

ACTUAL TEMPERATURE:—

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, September 12, 10 a.m.: Bar. 29.5; temp. 58° Weather—Dull.

SALES FOR THE ENSUING WEEK.

TUESDAY—
Sale of Palms, Ferns, Greenhouses, Piping, &c., at the Nursery, Bury Street, Lower Edmonton, at 12.45, by Protheroe & Morris.

WEDNESDAY—
Sale of Bulbs at 67 and 68, Cheapside, E.C., at 1 o'clock, by Protheroe & Morris

FRIDAY—
Sale of Orchids at 67 and 68, Cheapside, E.C., at 1 o'clock, by Protheroe & Morris.

Progress in Dahlias.

It is remarkable that the great family of the Compositae furnishes the chief glories of the flower garden in late summer, autumn, and winter. Already the beds and borders are gay with Dahlias, which will soon be followed by the innumerable types of perennial Asters, better known in gardens as Michaelmas Daisies. Lastly, there is the wealth of Chrysanthemums which nowadays extend the season of flowers to Christmas and the New Year.

The Dahlia being the tenderest of these plants, it is only fitting that it should open the season, and the exhibition of the National Dahlia Society in the Drill Hall, Westminster, on Tuesday last, showed that, although fewer persons are now growing and exhibiting flowers, many still continue to take a great interest in Dahlias, and that progress in the raising of new types and varieties is being well maintained.

Some critics of the flower contend that the Dahlia is too formal and stiff in appearance to make a wide appeal. This may certainly be true of the older types, such as the show and fancy varieties, but this cannot be advanced in the case of the beautiful single varieties; nor is it true of the newest type of "Star Dahlia," for which we are indebted to the firm of Messrs. J. Cheal and Sons. The Collerette, Paeony-flowered, and miniature Cactus Dahlias are all of comparatively recent origin, and in all these we have material of great decorative value for gardens. The larger-flowered varieties, and those generally known as decorative Dahlias, are especially suitable for furnishing large beds and for the foreground of the shrubbery border; in this latter position their imposing stature and brilliant flower-heads show to particular advantage.

The Cactus forms include many which are suitable for massing out-of-doors, but there has been a tendency in late years for raisers to pay more attention to varieties in this section suitable for exhibition than to those adapted to garden decoration, and many of the choicest novelties have grave defects, such as short flower-stems or sparse blooming, with the result that in gardens the foliage is more conspicuous than the blooms. Some of this section are superb border plants, and raisers should endeavour to obtain a greater selection of Cactus varieties of the best garden type. The new rule of the National Dahlia Society requiring all varieties submitted to the Floral Committee for certificates to be exhibited without artificial support was made for the express purpose of eliminating those with short or weak stems, and which do not hold the blooms sufficiently erect to allow the full beauty of the flower to be appreciated.

Varieties of the Star type are excellent for furnishing cut blooms; the stems are exceptionally long, the heads stand up well, and the growth of the foliage is not so dense as in many of the older varieties. Perhaps the best in this section is White Star, which was illustrated in *Gard. Chron.*, September 26, 1914, fig. 89.

One of the latest varieties, Southern Star, which received the Royal Horticultural Society's Award of Merit on August 27 last, is illustrated in fig. 38. The Star Dahlia originated as a seedling from a single variety, crossed, most probably, with a Paeony-flowered variety. The first one distributed by the raisers was Crawley Star, and from this was obtained the beautiful white form referred to above. Yellow Star and Lowfield Star, the latter with pink florets marked with darker colour at the bases, are two others of high merit.

The claims of the Pompon varieties as decorative garden plants must not be overlooked, for many of these elegantly shaped Dahlias possess long flower-stalks and a compact habit of growth. They are extremely useful for floral decorations, for cut blooms remain fresh for a long period. The Collerette forms are even more valuable in the garden, as their bright and shapely blooms are freely borne and carried well above the foliage. Some of the varieties of this type, such as Canopus, illustrated in fig. 39, are very regular in outline, and their symmetry of form would appeal to the most critical florist.

Sir Albert Rollit.—Sir ALBERT K. ROLLIT, V.M.H., has been re-elected chairman of the Horticultural Education Committee of the Senate of the University of London.

Phosphatic Fertilisers.—Owing to the impossibility of meeting all demands for basic slag, it is necessary that growers should make greater use of superphosphate, the supplies of which are relatively satisfactory. As compared with basic slag, half the quantity of superphosphate may be expected to give equally good results on cereal crops, and for cereals and spring crops generally, superphosphate is usually to be preferred on account of its greater solubility. Further, superphosphate may safely be mixed with sulphate of ammonia, thus economising time and labour. Economy should be exercised in the use of basic slag, in order that a moderate dressing may be available for as large an area as possible. For autumn-sown crops the use of basic slag might, broadly speaking, be restricted to the heavier clay soils, where both phosphates and lime are deficient, and the dressing should not usually exceed 4 cwt. per acre. Even where superphosphate cannot be applied as an autumn dressing growers should order as much as possible of their supplies for delivery during the autumn.

Agriculture in 1918.—The returns of acreage and live stock collected on June 4 last show that the total arable area in England and Wales this year is 12,398,730 acres, representing an increase of 1,152,620 acres, or 10 per cent. over the arable area of 1917. This is the largest area returned for the past twenty years. The area under permanent grass is 14,588,900 acres, a decrease of 1,246,470 acres on the year. The total area under crops and grass thus amounts to 26,987,630 acres, as compared with 27,081,480 acres in 1917. The greater part of the ploughed grass land has been placed under Wheat and Oats. The increase in the area under Wheat is 638,260 acres, or 33 per cent., and the total now under this crop amounts to 2,556,740 acres, which is the largest since 1884. Oats this year cover 2,778,980 acres, the largest on record, and 520,070 acres (23 per cent.) more than last year. The other Corn and Pulse crops also show increases; Barley by 42,000 acres, Rye by 45,000 acres, Beans by 40,000 acres, and Peas by 19,000 acres. To these cereal areas have to be added 141,580 acres under Mixed Corn now for the first time separately distinguished, the returns of such crops having previously been divided between the various Corn crops, according to the kinds grown. The total area under Corn and Pulse (Wheat, Barley, Oats, Rye, Beans, Peas and Mixed Corn) this year thus amounts to 7,481,000 acres as compared with 6,035,000 acres in 1917; an increase of 1,446,000 acres, or 24 per cent., and the largest area under Corn since 1879. Potatos have been increased by 125,850 acres, or 25 per cent., and the total area (633,840 acres) is much the largest on record. Most other crops naturally show a decline, especially Turnips and Swedes, which are reduced by 6 per cent., and are the lowest on record; but the Mangold area is slightly greater, and Flax this year covers 18,400 acres—more than seven times the area of last year, and the largest but two (in 1869 and 1870) for the past fifty years. The area under Clovers, Sainfoin, and Rotation Grasses has been reduced by 400,000 acres (16 per cent.), and the total (2,095,000 acres) is the smallest on record. Of this 1,446,500 acres were reserved for hay, which is the smallest area ever returned, and represents a decline of 235,000 acres on the year. Of the permanent grass 4,300,000 acres (nearly half a million less than last year) were reserved for hay. The total hay area thus amounts to not quite 5,750,000 acres, or 730,000 less than in 1917, and the smallest since 1885.

Glasgow and South-Western Railway Station Gardens.—The prizes for the best-kept station gardens on the system of the Glasgow and South-Western Railway Company have now been awarded by the judges, who visited the stations on three occasions during the season. They are divided into five classes, the premiums in these being respectively £5, £4, £3, £2 and £1. In the first class are the following: Mr W. R. BECKETT, Drybridge; Mr. JAS. HOUSTON, Closeburn; Mr. D. KELLY, Holywood; Mr. WM. NICHOLSON, Maxwelltown; Mr. JOHN INGLIS, Dalmellington; Mr. W. PATERSON, Glenside; Mr. THOS. COYLE, Dalbeattie; Mr. C. AULD, Alloway; Mr. R. MUIR, Carronbridge; Mr. JAS. DUNLOP, Cunninghamhead; Mr. ALEX. LESLIE, Paisley West; and Mr. JOHN RAE, Dumfries House.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Corn Production (Amendment) Act, 1918.—As considerable confusion still appears to exist as to the effect of the above Act, I feel that the following remarks may be of some assistance to your readers who are interested in the question. Part IV. of the Corn Production Act, 1917, dealing with the enforced cultivation of land, should have come into force on August 21, 1918, and under that Part certain rights of appeal and compensation were granted. The Government, however, wished, until the conclusion of the war, to exercise the powers which they claim under the Defence of the Realm Act Regulations, and introduced what is now the above Act, granting them the continued use of such powers. The Bill as introduced contained no rights of appeal and no statutory right to compensation, and consequently it was subjected to considerable opposition. The Government, admitting the reasonableness of the criticisms advanced, accepted certain Amendments, and the present position is as follows: (1) If a notice is served ordering a change in the mode of cultivation or in the use of the land (*e.g.*, the ploughing-up of pasture), or determining the tenancy of any land, although such notice is issued under the Defence of the Realm Act the farmer will have a right of appeal to an independent arbitrator. There is, however, this qualification, that if the notice is served "solely for the purpose of securing that the land shall be cultivated according to the rules of good husbandry," no appeal is allowed, unless the notice is one determining a tenancy; (2) if the Board of Agriculture or their agents decide to enter into possession without in fact determining the tenancy, notice will be served and a similar right of appeal granted before such possession is taken. Should, however, the land be required for gardens or allotments, or possession is taken solely to secure good cultivation, no notice will be served and no appeal will be allowed; (3) where an appeal is given the owner and occupier have the same rights of appeal, and notices will be served on both. Where possession is sufficient cause to the arbitrator, Orders issued by the Board of Agriculture or their agents, compensation can be claimed and, in default of agreement will be assessed by an independent arbitrator instead of by the Defence of the Realm Losses Commission, and the farmer can now claim this compensation as of legal right instead of as heretofore merely as a matter of grace. These concessions are of very great importance to all those interested in agriculture, and should do much to abolish any friction which might exist between agriculturists and those responsible for the issuing of compulsory Orders, with the result that the food supply, which is vital to the interests of the country, should be materially increased. The Land Union hopes at an early date to issue the text of the Act together with a full explanatory note of the present position.—*Desborough, Chairman, The Land Union.*

Old Gardening Books (see pp. 57, 71). I agree with Mr. Roberts' comment that all lists of gardening books fall short of what is wanted. The bibliographical list in the Hon. Evelyn Cecil's *History of Gardening in England* ought certainly to have been brought closer up to date. For all practical purposes it ends almost at the same point as Johnson's. And yet a large number of works on horticulture and allied subjects have appeared since the last date mentioned by these two authors. Although old seedsmen's catalogues are a part of gardening literature, it does not seem to be desirable that they should figure in a bibliography. They are a separate and distinct class of literature, and it would be unwise to encumber any horticultural bibliography with them. In all my contributions on floricultural bibliography I have generally excluded anything purely in the nature of a trade catalogue. There are some cases in which exception might be made, but they are few. John Webb's catalogue of seeds and roots may be one. I do not know it, but Robert Edmeade's catalogue, published in 1776, is certainly more than it might be supposed to be. It is entitled "The Gentleman and Lady's Gardener, containing the modern method of cultivating the kitchen garden, flower garden, etc. . . . with a general catalogue of seeds, plants, and roots . . . to which is added a catalogue of bulbous-rooted flowers and their prices," etc. There are 156 pages. The Latin names are given to each plant according to the Linnean system of classification. There is a monthly calendar of operations. The priced lists and names are of considerable interest, and the work, instead of being a mere trade catalogue, is a cultural guide or *vade mecum*, and should be placed in a higher literary rank than many of the more modern publications of its kind.—*W. H. P.*

——There is an old book called "*The Complete Gardiner; or, Directions for Cultivating and Right Ordering of Fruit Gardens and Kitchen Gardens*." By Monsieur De la Quintinye. Now commendably abridged and made of more use, with very considerable improvements by George London and Henry Wise. 4th Edition. Corrected, 1704. With a number of plates, plans, etc. Can any reader inform me as to the probable value of the book.—*H. J. Shelley, Desborough Lodge, High Wycombe.*

Collecting Herbs. In many old established gardens large quantities of herbs are grown which are not required for use and are ultimately wasted; it should be possible to obtain a beverage from those which could be used and refreshing, and quite as palatable as some of the tea which is now on the market; we have also large quantities of native herbs, such as Marjoram, Thyme, Wood Sage, and others; if these were included there would be a large supply of material which would only need collecting and drying. Can any reader of the *Gardeners' Chronicle* furnish me with a recipe for utilising these herbs, for if less tea is imported more shipping will be available for other purposes.—*W. H. Divers, Westbourn, Hook, near Surbiton.*

SOCIETIES.

ROYAL HORTICULTURAL.

SEPTEMBER 10.—It was a pleasure to find such a large attendance at the meeting held on Tuesday last, and to see the Drill Hall filled with exhibits. Dahlias were prominent flowers even in the classes provided by the National Dahlia Society, and Roses were extensively shown in the classes provided by the National Rose Society. Orchids were another fine feature, and vegetables were well shown.

The Floral Committee granted one First-class Certificate and eight medals. The Fruit and Vegetable Committee awarded two Cultural Commendations and three medals. The Orchid Committee's awards consisted of one First-class Certificate, one Award of Merit, and two medals. The Joint Dahlia Committee selected nine Dahlias for award.

FIG. 30.—THE HON. PARKMAN'S HAYWARDS VARIETY (see p. 112).

Floral Committee.

Present: Messrs. H. B. May (in the chair), John Green, Sydney Morris, R. W. Wallace, A. G. Jackman, J. F. McLeod, G. Reuthe, John Heal, W. Cuthbertson, C. R. Fielder, Wm. H. Morton, George Paul, Arthur Turner, H. J. Jones, J. W. Moorman, Jas. Hudson, Chas. E. Pearson, E. F. Hazelton, W. P. Thomson, E. H. Jenkins and Herbert Cowley.

FIRST-CLASS CERTIFICATE.

Berberis concinna. This is a very handsome Barberry that makes a fair-sized bush of graceful habit. The spiny leaves have a white under surface, and this is most conspicuous on the leaves of the new growths. The berries are one-third of an inch long, generally in pairs, and they are slightly elongated oval in shape, coral-red when ripe, and yellowish-green before ripening. The fruits are freely produced, and as they are pendulous the decorative value of the sprays is very great. Shown by Messrs. R. WALLACE AND CO.

INTERESTING PLANTS.

Large fruiting sprays of Rosa Moyesii were very attractive in a group of autumn fruiting shrubs staged by Messrs. R. WALLACE AND CO. In Mr. REUTHE'S exhibit a pan of Schizocodon ilicifolius was a pleasing feature, the glistening bronze-green leaves attracting much attention. Mr. W. MILLER had a bold stand of Tritoma nobilis among other hardy flowers, and in a group of Delphiniums Mr. W. WELLS, junr., made a fine feature of the deep violet-blue variety named Cossack. Mr. L. R. RUSSELL'S stove plants were greatly admired, especially the Bertolonias under large bell glasses. Messrs. B. LADHAMS' hardy herbaceous Lobelias had many admirers, but their blooms of Gaillardia Rownham's Queen attracted even more attention; these are pale yellow with crimson centres.

MEDALS AWARDED.

Silver-gilt Banksian.—To Mr. L. R. RUSSELL, for stove plants, and to Mr. G. REUTHE for hardy plants. *Silver Flora.*—To Mr. G. W. MILLER, for hardy flowers. *Silver Banksian.*—To Mr. W. WELLS, junr., for Delphiniums. *Bronze Flora.*—To Messrs. J. CHEAL AND SONS, for coloured and berried shrubs, and to Messrs. H. B. MAY AND SONS, for Ferns and Veronicas. *Bronze Banksian.*—To Messrs. B. LADHAMS, LTD., for hardy flowers, and to Messrs. R. WALLACE AND CO., for fruiting sprays of hardy shrubs.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Sir Harry J. Veitch, Messrs. Jas. O'Brien (hon. secretary), Frederick J. Hanbury, William Bolton, W. H. White, J. Charlesworth, Chas. H. Curtis, T. Armstrong, and Fred Sander.

AWARDS OF MERIT.

FIRST-CLASS CERTIFICATE.

Laelio-Cattleya President Wilson (*L.-C. Thyone* × *C. Dowiana aurea*), from Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells.—A magnificent hybrid, and by far the best of its class, with the fine form of C. Dowiana aurea and its firm substance intensified. The broad sepals and petals are bright yellow, the wavy-edged petals being finely displayed; the large lip, which in its colouring much resembles C. Dowiana Rosita, is carmine-crimson with rich orange-coloured lines extending from the base to the front, where they are of a lighter tint.

AWARD OF MERIT.

Brasso Cattleya Olympus Langley variety (*C. Hardyana* × *B. C. Madame Chas. Maron*), from Messrs. FLORY AND BLACK, Orchid Nursery, Slough.—A fine addition to a favourite class, and distinguished by the broad expansion of its fringed labellum and an unusually large, clear yellow disc to the lip. The colour is white tinged with lilac, the lip being of the darker shade.

GROUPS.

Messrs. STUART LOW AND CO., Jarvisbrook, Sussex, were awarded a Silver-gilt Flora Medal for an extensive and well-arranged group in which all the plants were excellently well grown and profusely flowered. A selection of Laelio-Cattleyas and Catt'eyas included the new C. Iris Buttercup, with bright yellow sepals and petals and claret-coloured lip with broad, yellow margin, and C. Gaskelliana My Lady, a pretty white form with mauve blotch on the lip, the spike bearing five flowers. Fine plants of Vanda coerulea, the rose and white Oncidium incurvum, and the yellow O. varicosum were arranged with dwarfer Orchids.

Messrs. CHARLESWORTH AND CO., Haywards Heath, were awarded a Silver Flora Medal for a good group in which their home-raised Miltonias were effective, and included two fine new forms of M. vexillaria, viz. Marshal Foch, with large, light rose-coloured flowers, the labellums of which were nearly 4 inches across, and Dulcies, coloured bright magenta-rose with a very distinct mark on the lip. A good selection of Odontoglossums and Laelio-Cattleyas, including a finely-coloured form of L.-C. Aquam, were included in this exhibit.

Messrs. J. AND A. MCBEAN, Cooksbridge, staged a small group in which were a good form of Cattleya Hardyana alba, Vanda Sanderiana, Cattleya Venus, Brasso-Cattleya Nodina, and the now rare Rodriguezia secunda, with four sprays of rose-pink flowers.

Messrs. ARMSTRONG AND BROWN showed Cattleya Ella Orchidhurst variety (bicolor × Warscewiczii), a fine flower of a light salmon shade tinged with yellow, and broadly expanded violet-crimson lip.

Messrs. FLORY AND BLACK showed the white-petalled Cattleya Warscewiczii Fran M. Beyrodt in excellent form.

Fruit and Vegetable Committee.

Present: Messrs. Joseph Cheal (in the chair), Owen Thomas, W. Bates, Edwin Beckett, E. A. Bunyard, P. W. Roach, W. H. Divers, George P. Berry, A. R. Allan, J. C. Allgrove, Fred G. Treseder, and Sir Albert Rollit.

This Committee was occupied with business for a longer time than usual. From the R.H.S. gardens a small collection of Haricot Beans was brought, and cooked examples of each variety were tasted. We understand that a report upon the cropping and culinary qualities of these Beans will be published in due course.

No award was granted to a novelty, but Messrs. BARR AND SONS gained a Cultural Commendation for eighteen finely grown and heavily fruited plants of Tomato Barr's Scarlet Beauty. This is a highly coloured form bearing even-sized, smooth fruits in clusters of six to ten each. The plants carried an average of six clusters each. (Silver-gilt Banksian Medal.)

Messrs. SUTTON AND SONS were awarded a Silver-gilt Banksian Medal for a collection of vegetables. Potatos, Spinach and Peas planted or sown on July 15 were exceptionally good, and proved very interesting. Runner Beans were also a great attraction, some pods of Prizewinner measuring 16 inches in length.

Several varieties of Figs grown and ripened out-of-doors at St. Anne's Hill, Chertsey, secured a Cultural Commendation and a Silver Banksian Medal for Sir ALBERT ROLLIT.

A new and attractive Apple obtained by crossing Cellini Pippin with Gravenstein was exhibited by Messrs. H. CANNELL AND SONS under the name of James Lawson.

NEW DAHLIAS.

The Joint Floral Committee, composed of members of the National Dahlia Society and of the Royal Horticultural Society's Floral Committee, sat at 10.30 a.m. to judge the new Dahlias submitted.

Present: Messrs. H. B. May (in the chair), D. B. Crane, E. H. Jenkins, H. J. Jones, Arthur Turner, Chas. H. Curtis, Joseph Cheal, John Green, J. A. Jarratt and J. F. McLeod.

The following Dahlias gained the Royal Horticultural Society's Award of Merit and also the National Dahlia Society's First-class Certificate:—

Defiance.—A handsome decorative variety, of large size, but in no degree heavy or ungainly. The colour is pink with a golden flush over the centre of the flower, which is carried on a long stiff stem.

Our Annie.—A rather small decorative Dahlia with two rows of florets, and a very useful variety for floral decorations, as the blooms are about 3½ inches across. The florets are pink, a lovely shade, with golden bases and golden shading running into the pink. The stems are dark, long, and stiff. These two varieties were shown by Messrs. J. BURRELL AND CO.

Sincerity.—A large white, decorative variety, very double, but with pointed segments. The heavy blooms are carried on stout stems, and they should be very useful for the making of wreaths and other large floral designs.

Bullfinch.—A large and finely formed Collerette Dahlia with broad, rounded segments of a clear, rich scarlet shade. The neat collar segments are yellow. The flowers are very attractive, and borne erect on stiff stems. These two varieties were shown by Messrs. J. STREDWICK AND SON.

Rising Star.—Although this has not the elegance of earlier members of the "constellation," it is a most attractive variety, as the colour is deep, velvety vermilion, with gold tips and lines. The blooms have two rows of segments, and, as in the case of other "stars," the stems are stiff and wiry. Shown by Messrs. J. CHEAL AND SONS.

Lady W. Thomas.—A medium-sized Collerette variety of good form. The ground colour is blush, but the centre of each segment is crimson, and there are rosy markings between this colour and the margin. The whitish collar is evenly developed.

Clematis.—A striking single variety eminently suitable for garden and floral decoration, but not of sufficiently rounded form for show purposes. The slender stems are long and wiry. The colour is clear rich mauve, with a narrow zone of yellow round the eye. The variety is well named. This and the foregoing variety were shown by Messrs. J. TRESEDER AND SON, Cardiff.

Oriole.—A very distinct decorative variety that might be classed as a semi-double Cactus Dahlia. The flowers have three rows of segments, which are broad at the base and pointed at the apex. The colour is rich orange-scarlet. Shown by Mr. J. T. WEST.

Péronne.—A bold and effective Collerette variety with full-sized, rounded flowers of a rich, soft scarlet colour, with a well-developed yellow collar. Stems long and stiff. We believe this variety was raised by Messrs. W. Treseder and Sons, of Cardiff. Shown by Mr. J. A. JARRATT, Anerley.

THE NATIONAL DAHLIA SOCIETY'S SHOW.

Messrs. W. TRESEDER AND SONS, Cardiff, were the only exhibitors of 24 Show and 12 Fancy varieties, and were awarded the 1st prize in both classes. In the former class the best varieties were Nugget, R. T. Rawlings, Penelope, Perfection, Gracchus, and David Johnson. The Fancy blooms were not quite so good; the best were Rev. J. B. M. Camm, Nansen, and Comte de le Saux. Messrs. TRESEDER AND SONS won the 1st prize for 6 blooms of one variety with a fresh and very evenly developed bloom of Shottisham Hero; 2nd, Mr. S. COOPER, Chippenham.

In the open classes for Cactus Dahlias there were no exhibits of 18 varieties or of 48 blooms, but Messrs. TRESEDER AND SONS were awarded the 1st prize in the class for 24 blooms with such sorts as Border King, Gigantic, and Dorothy Hawes. With excellent blooms of Valhalla, Mr. S. T. WHITE, Eastleigh, Hants, won the 1st prize for 6 blooms of one variety; 2nd, Mr. PRYOR, Hitchin.

Messrs. J. CHEAL AND SONS, Crawley, showed alone in the class for 12 vases of garden Cactus Dahlias; the exhibit was worthy of the 1st prize, which was awarded. The vases of Mary Purrier, Richard Box and Cygnet were very decorative. Only one of the classes for Pompon Dahlias was represented by an exhibit; the exhibitor was Mr. D. B. CRANE, Highgate, and he was awarded the 1st prize for a charming set of such varieties as Annie, Doncaster, Little Beeswing, Bacchus, and Little Gem.

Showing almost perfect vases of such sorts as Mikado, Hilda, Columbine, and Winona, Messrs. CHEAL AND SONS were awarded the 1st prize for 24 vases of Single Dahlias, and Messrs. TRESEDER were similarly placed for a graceful shower bouquet of Mrs. Irwin Dahlias.

Competition was rather disappointing in the classes for the popular and highly decorative Paeony flowered and decorative Dahlias. Mr. J. A. JARRETT, Anerley, won the prize for 6 varieties with appropriate foliage, showing such sorts as Meyerbeer, Mrs. J. A. Jarrett, and Old Gold; 2nd, Messrs. CHEAL AND SONS. Mr. JARRETT was also placed first for 6 vases of decorative varieties, with Mr. TOFIELD, Southampton, who was awarded 1st prize for a beautiful vase of Paeony-flowered varieties, second.

AMATEURS' CLASSES.

In this division the competition was better, and several amateurs whose ambition justified their entry into the open classes competed.

Of the Show and Fancy classes that for 24 blooms was not competed in; Mr. COOPER was placed 1st and Mr. J. WAITE, Chippenham, 2nd, for 12 blooms, and Mrs. S. MAY, West Grinstead, was 1st for 6 blooms.

Mr. C. LUCKIN, Pulborough, won 1st prizes for (a) 6 vases of garden Cactus, (b) 12 blooms of Cactus, (c) 12 blooms in four varieties, and (d) 6 varieties of Single Dahlias, and was 2nd for 9 vases of Cactus varieties. Mr. G. PRYOR, Hitchin, won the Dean Gold Medal with a good collection of 9 vases of Cactus Dahlias, which included Margaret Phillips, H. H. Thomas, and Julian, in splendid condition, and he was also placed 1st for 6 blooms of Cactus Dahlias.

Mr. A. BROWN, Seagrave, was placed 1st, and Mr. J. WAITE 2nd, in the class for 6 vases of Pompons. Mr. D. B CRANE excelled in the class for 6 12 vases of Single and 6 3 vases of Star Dahlias, while Mr. JARRETT took 1st prizes in the classes for 6 4 vases of Incurved and (b) 6 of Paeony-flowered Dahlias, and Mr. H BROWN, Luton, for 6 vases of Collerette Dahlias.

Messrs. J STREDWICK AND SON won the Gold and Silver Medals which they offered for the best seedling exhibition Cactus Dahlias on a wire frame, with fine examples of Pennant

CORY CUP.

Messrs. CARTER PAGE AND CO. were the only entrants in the annual competition for the Cory Challenge Cup, which is offered for the best display of garden Dahlias. The decision lies with the Council of the R.H.S., and in the absence of competition the cup was not awarded. All sections of the flower were represented, and the individual blooms were the acme of freshness and high quality, and arranged with great skill.

NATIONAL ROSE SOCIETY'S CLASSES

THE autumn show of this society, held in conjunction with the R.H.S. meeting, assisted materially in the general success of the fixture. The various trade displays were admirable.

SEEDLING ROSES.

This section was decidedly weak, and for some reason not readily apparent the three novelties failed to reach the high standard that is usually associated with the shows of this society. A Certificate of Merit was awarded to Capt. Fane Bold, a dark crimson H.P. Rose, shown by Messrs. ALEX. DICKSON AND SONS. As seen at the hall it was a good Rose, rather weak in the stem, though of good form and size; the bloom was rich and very effective of mildew, but the blooms possess the indispensable quality of fragrance, and this may have induced the award. Claire Jacquier, of Messrs. A. Haworth, the other two sorts, were due badly in poor condition, but they were splendidly shown a month ago.

GROUPS OF ROSES.

These in search of good autumn flowering varieties could have spent time much more profitably in inspecting the magnificent trade displays than with the few seedlings above mentioned. In spite of many handicaps, half a dozen well-known firms set up admirable collections of fresh and fragrant Roses, often in such masses as to give an instant impression of great floriferousness.

Of the many sorts so abundantly shown, it was noticeable that those of yellow colour and shades, Constance, Mrs. Wemyss Quinn, Rayon d'Or, Lady Hillingdon, and the like "took the eye," though Ophelia was the "Rose of the show."

Mr. E. J. HICKS was awarded a Gold Medal for an outstanding exhibit, which included splendid vases of Red Letter Day, Princess Mary, Ophelia, Lady Hillingdon, Chas. E. Shea, Rayon d'Or, Florence H. Veitch, and the pale pink, semi-double Queen of the Belgians.

In the fine collection which won a Silver-gilt Medal for Messrs. ALEX. DICKSON AND SONS, we noted Clarice Goodacre, Lady Pirrie, K. of K., Mrs. Wemyss Quinn, and Alexander Emslie, rich crimson, as being worthy of special mention, while in the collection which won a similar high award for Messrs. E. CANT AND CO. the outstanding vases were of Constance, General McArthur, Ophelia, Irish Fireflame, Modesty, and Jessie.

Silver medals were awarded to the Rev. J. H. PEMBERTON, who had generous quantities of Pax, Moonlight, and Rayon d'Or; and to Messrs. B. R. CANT AND SONS, in whose collection Lady Hillingdon, Mdme. Ed. Herriot, Snow Queen, Muriel Dickson, and Mrs. Alfred Tate were excellent. A Bronze Medal was awarded to Mr. HARRY DREW for a smaller group.

DECORATIVE CLASSES.

In several classes medals were awarded for baskets, and the floral arrangements were all beautiful, and well worthy the awards.

Mr. E. J. HICKS was the only exhibitor of 3 baskets, and was awarded a Silver-gilt Medal for good blooms of Red Letter Day, Joanna Bridge, and Princess Mary. Mr. HICKS also was awarded a Silver Medal for a bowl of Isobel, a rose-tinted sport of fine size and much beauty.

A Silver-gilt and a Silver Medal were awarded to Mrs. COURTENEY PAGE for bowls of roses. Mrs. J. M. MCKAY and Mrs. OAKLEY FISHER received Silver-gilt Medals for displays of Roses, and the latter lady also won a Silver Medal for a bowl of Roses, while Mr. A. DE V. FRYER was rewarded with a Silver Medal for a charming decorative exhibit of Irish Elegance. Bronze Medals were won by the Rev. J. H. PEMBERTON and Mr. HY. DREW for the varieties PAX and Irish Elegance respectively.

VEGETABLE SHOW AT ST. ALBANS.

IN their 1915 Catalogue of Vegetable and Flower Seeds Messrs. Ryder and Son, Ltd., St. Albans, offered 20 prizes of £5 each for the best specimens of Runner Bean, Broad Bean, Haricot Bean, Long Beet, Round Beet, Cabbage, Carrot, Cauliflower, Cucumber, Celery, Leek, Onion, Parsnip, Pea, Salsafy, Sweet Corn, White Turnip, Yellow Turnip, Tomato, and Vegetable Marrow. Entries were restricted to one of each, though any number could be sent in, in any one class or any number of classes. There was no entrance fee, and no stimulation as to varieties or where the seed was purchased. Nearly 500 exhibits were staged on the 5th inst., and they were judged by Mr. Ed. Beckett and Mr. E. Molyneux. Exhibits were sent from all parts of the British Isles, and these on the whole, were of excellent quality. The exhibits of Onions filled one table, and the majority were fine, well-matured bulbs, the heaviest specimen weighing 3 lbs. 6oz., which is a credit to the grower. The Runner Beans were the finest Runner Beans we have ever seen, the pods being 18 inches long and perfect in shape. Many others were from 10 inches to 15 inches in length. Pods of Broad Beans containing seven or eight large Beans were arranged on a table next to Haricot Beans containing nine or ten Beans. Parsnips 2 feet to 3 feet long, one measured 3 feet 6 inches, and Carrots 2 feet or more in length were assembled in hundreds. Turnips and Beets were present in quantity, but the samples were very uneven and many were large and coarse. The winning roots however, and a fair proportion of the others were of good quality. Vegetable Marrows were of all sizes, some weighing from 25 lbs. to 35 lbs. each, but the monsters were disqualified as being only suitable for jam-making. The winner was a large, clean specimen, quite young, probably weighing 10 lbs. or more. Salsafy and Sweet Corn were represented by a comparatively large number of exhibits. Though the season was somewhat late a considerable number of Peas were exhibited, the pods containing ten or eleven Peas of perfect colour and shape. Tomatoes were not numerous, probably owing to the difficulty of sending ripe fruit by rail, but the quality of those exhibited was good, and it was not an easy matter to determine the best. Cucumbers resembled the Marrows in that half the specimens sent were too old, though a few were young and of good quality. Leeks and Celery were plentiful and of good size, as also were Cabbages and Cauliflowers, the latter being medium sized, very firm and white. The winning cabbage measured 2 feet across, and was well shaped, firm, and young.

The following is the list of prize-winners:—

Runner Bean: J. SELBY, Flock House, Taunton; Broad Bean: D. WILSON, 17, Croftbeat Terrace, Glashurn, Keighley; Haricot Beans: W. C. PAGRAM, 3, Redfern Cottages, New Road, Weybridge; Long Beet: J. DEVOY, 30 Dalrymple Street, Stranraer; Globe Beet: M. HOAD, 96, Albemarle Road, Willesborough, Ashford; Cabbage: A. PINNOCK, 42, Prospect Road, St. Albans; Carrot: J. MCRONALD, Station House, Philorth, Fraserburgh; Cauliflower: J. I. PINNOCK, 2, Albert Street, St. Albans; Celery: J. DARQUE, Plunderheath, Haydon Bridge; Cucumber: H. BOWLES, 27, Burleigh Road, Malden; Leek: W. CARTLEDGE, Garmondsway, Coxhoe; Parsnip: C. BATE, Post Office, Overton Bridge, Bridon; Salsafy: C. WEBSTER, The Rookery Gardens, Westcott, Dorking; Maize: W. H. THORNE, The Lodge, Dimcroft, Staines; White Turnip: T. AVERY, The Gardens, Gaddesden Place, Hemel Hempstead; Yellow Turnip: H. BOSLEY, 61, Fern Street, Boothtown Road, Halifax; Peas: W. B. CURTIS, Perranwell Station, Carnwell, Truro; H. WHEELER, Wenvoe, near Cardiff; Tomato: G. HACKER, Manor Cottages, Shirrell Heath; Vegetable Marrow: F. EATON, 16, Ladysmith Road, St. Albans.

H.M GRETNA FACTORY SHOW.

THE first annual flower show in connection with the Gretna Factory Horticultural Association was recently held in the Institute Hall, Gretna. There was an excellent competition, no fewer than 730 entries being made. Vegetables formed the principal feature of the exhibition, and these were of exceptionally fine quality as a whole, the Potatos being both numerous and of sterling quality.

The show was opened by Mr. J. C. Burnham, C.S.I., the superintendent of the factory, Mr. J. Harkness, Town Manager, occupying the chair. Mr. Burnham made an interesting speech, in which he give many encouraging details regarding the horticultural and agricultural efforts being made at the factory. The prize list is a long one, and we have only room to publish a few details of some of the leading classes. For the heaviest crop of Potatos grown on 20 roots in a continuous row Mr. C. BURLEY was placed 1st, with a crop of 74 lbs. 8 oz. of the variety Duchess of Cornwall. There were 42 competitors in this class. For the best aggregate of points in the vegetable section Mr D. MAXWELL was placed 1st, and he was also awarded the 1st prize for a collection of vegetables. A number of prizes were offered in the garden and allotment competition, in which Mr W. MCWHIR won the 1st prize for the best kept Ministry bungalow garden in the Gretna district, and Miss JOHNSTONE-DOUGLAS that for a similar garden in the Eastriggs district. For the best kept allotment in the Factory area Mr. JOHN ARNOTT, Eastriggs, was placed 1st.

CROPS AND STOCK ON THE HOME FARM.

RYE.

LAST week I referred to the value of Rye for sheep food. I have just threshed the crop from 11 acres of this cereal, and the yield is 400 sacks—quite a full crop considering that 8 sacks per acre is regarded as a maximum yield. Now that Rye is so much required by the miller for flour, it would seem that this cereal is almost as valuable a crop as Wheat to grow, especially on poor land. No other cereal crop succeeds so well under inferior culture and poor manuring as Rye does, but I need hardly say the crop responds well to liberal treatment. Nitrogenous manures should be applied carefully, as the straw is longer and more slender than in any other cereal, and with heavy manuring would be more liable to fall. Rye is usually sold at the same price and weight per bushel (56 lbs.) as Wheat.

Those who have poor land to deal with might do well to sow Rye in September, first spreading 3 cwt. of superphosphate per acre. Early sowing is most important, in order that the plants may obtain a thorough roothold before winter.

ROOTS.

In southern counties Turnips are very poor, owing to the ravages of the Turnip fly. The outlook for sheep food during the winter and spring is not encouraging to those with a breeding flock to provide for. Backward patches should be encouraged to grow more vigorously by the aid of sulphate of ammonia sown evenly

at the rate of ¾ cwt. per acre. Keep the horse-hoe at work between the rows to accelerate growth as much as possible.

Swedes are generally a good crop, that will prove most useful in March and April to the sheep farmer.

Mangolds have improved very much, but many plots had to be ploughed owing to the attacks of Turnip fly—a most unusual experience with Mangold.

Farmers with a poor prospect of roots for sheep will be well advised to sow more Rye, at the rate of 4 bushels per acre, Winter Barley, Vetches, and Trifolium, both early and late sorts. All such crops will be useful in the early spring months.

WINTER OATS.

This crop has this season been a success, giving yields with plenty of straw, which is an important item. The advantages of winter over spring sown Oats are many. First, they ripen a fortnight in advance of those of the other section, enabling harvest to be commenced earlier, thus easing the harvesting of Wheat and spring-sown Oats, which at times ripen with a rush, and, if not cut promptly, much of the Corn is "butted." When Oats for use run short before harvest, the earlier ripening winter Oats fill the gap; and, lastly, Charlock does not affect this crop, as it does all too often spring-sown Oats. September is the best month in which to sow winter Oats, at the rate of three bushels per acre. Choose a clean Wheat stubble, thoroughly burying the straw by the aid of the skim coulter affixed to the plough. The ground once ploughed, well harrowed, and the seed sown broadcast or drilled, is all the preparation required. Either the black or the grey variety is equally good. *E. Molyneux. Swanmore Farm, Bishop's Waltham.*

TRADE NOTES.

FUEL RATIONING FOR MARKET GARDENS.

WHERE adequate supplies of coal for agricultural purposes cannot be obtained through the ordinary trade channels, application should be made immediately to the County Agricultural Executive Committee. The Food Production Department has made arrangements with the Controller of Coal Mines which it is hoped will ensure such supplies that are strictly necessary on the farms during the coming winter and spring. "Agricultural purposes" include steam ploughing, threshing, pumping, "and other direct farm uses," the work of blacksmiths engaged in repairing and making agricultural implements and shoeing farm horses. Work on market gardens and nurseries also comes within the term, but whereas it is hoped to supply the farmer with his full quota of fuel, the allowance to market gardens and nurseries has been cut down by about 20 per cent. The County Committees will not entertain any application unless an effort has been made to obtain coal from the usual coal merchant or factor and has failed.

ANSWERS TO CORRESPONDENTS.

ASPARAGUS PLUMOSUS NANUS: *J. P. and S.* Sow the seeds, as soon as they are ripe, in pans or beds of light soil in a house having a temperature of 70°. As soon as the seedlings are large enough to be handled easily place them in small pots, in a compost of sandy loam, old manure and leaf mould. If you require pot plants, place several seedlings together in the small pots and eventually place each potful in a 5-inch or 6-inch pot. A lower temperature will suffice when the plants are thoroughly established. If the feathery growths are needed for floral decorations set out the best individual plants in a well-drained bed of soil. In either case the plants will receive great benefit from frequent applications of diluted liquid manure when well rooted and commencing to grow freely.

BOOK: *T. W. B.* The best book on Conifers is *Veitch's Manual of Coniferæ*, but we believe the work is out of print, and can only be obtained from the second-hand booksellers.

CANTELOUP MELONS: *Melon.* The plants have either had too much or too little water, or they may have suffered from delay in planting. Canteloup and other Melons succeed best in heated pits, and should be grown in a temperature not lower than 65° at night, rising to 80° during the day, with plenty of moisture in the atmosphere and at the roots until the fruits begin to ripen.

GARDENING DICTIONARY: *H. G. H.* Nicholson's *Dictionary of Gardening* is out of print, but second-hand copies may be obtained occasionally through second-hand booksellers. It is probably the best work of its kind for a British gardener. The new edition of the *Standard Cyclopædia of Horticulture*, by Prof. L. H. Bailey, is an American work in six large quarto volumes, obtainable from Messrs. Macmillan and Co. A smaller and very useful book is the latest edition of Johnson's *Gardeners' Dictionary.*

GRAPES FAILING TO COLOUR: *Constant Reader.* As the roots of the vines are outside, moisture from watering plants in the house would not be detrimental to the colouring of the Grapes, provided sufficient ventilation was given. There are many circumstances which contribute to the lack of colouring—shanking, i.e., the withering of the berry-stems, is one of them, and this may be the result of insufficient nourishment, heavy cropping, mutilation of the roots, or the removal of a large quantity of leaves during the growing season. Shanked berries never become sweet. The early part of the summer was very dry, and vine borders needed an abundance of water, especially where the soil is light and the situation fully exposed to sunshine. If the border is cropped, the necessity for watering the vines would be much greater. When other plants are grown on a vine border they should only be surface-rooting subjects, not gross feeders like the members of the Brassica family, and no digging should be done during or immediately before the growing season of the vines. When the feeding roots of vines are 3 feet or more below the surface they cannot obtain sufficient air in a close soil, and none of the growths above ground will be perfectly developed. In bad cases it is advisable to raise the roots carefully in the autumn and plant them in a little fresh soil.

GRAPES RIPENING: *M.* Your Grapes should finish their ripening without further fire-heat, provided the winery is carefully ventilated and a little air admitted through the top and front ventilators at night. March 1 would be a good time to close the winery, as then artificial heat need not be provided except in very wet, cold weather. All sub-laterals should be pinched out and the house kept as cool as possible after the Grapes are cut.

GREASE BANDING FRUIT TREES: *L. D.* You will find a reference to the grease-banding of fruit trees on p. 101 of the last issue. As a preventive moisture grease-banding is extremely useful, inasmuch as thousands of wingless moths may be caught on the greased bands in a small orchard. As the trapped moths cannot lay their eggs on the branches of the trees it is obvious that subsequent attacks of caterpillars will be reduced to a minimum. Both the bands and suitable grease may be purchased from horticultural sundriesmen and seedsmen. The bands should be grease-proof and sufficiently wide to permit of their being tied at top and bottom; the ties must be sufficiently tight to prevent the moths from crawling underneath the bands. The grease should not come in contact with the stem of the tree. Place the bands at a convenient height up the stems of the trees in order that they may be re-greased rapidly as occasion requires.

HEDGING-HOOK: *C. C. B.* You will probably obtain the particulars required on application to Messrs. W. Wood and Sons, North British Wharf, Wood Green, London, N.

LAYING OUT A ROCK GARDEN: *F. R.* There is no book which will give you any definite instructions suitable for your particular piece of ground, but you will find *The Rock Garden*, by Mr. Reginald Farrer, which may be obtained from our publishing department for 5s., post free, exceedingly helpful not only in forming your rock garden, but also in selecting the plants. From your sketch, especially in view of the fact that you must keep the rock garden low in order to prevent interference with the view from your window, it would appear that a simple rock bed of varied front and ends should suit the position best. By a careful breaking-up of the front line behind the edge of the cement path and at each end you could obviate any appearance of formality. We have seen a rock bed about the same breadth, which is only about 18 inches at the highest part, but looks much higher from the way it is planted. If you make the highest points along the centre you will require to make a paved path next the trellis, but in view of the limited width you might find it more satisfactory to form a very narrow paved path next the trellis; then build a low, rough wall of stones or old bricks to the height of your rock garden and then gradually bring the latter from that height to the front next your cement walk. The former plan would look better, but it reduces the width of the rock garden. This is proceeding on the assumption that you cannot build your rock garden against the trellis, which it would be a pity to do. There is no reason why you should not be able to construct a pretty rock bed capable of growing many good Alpines.

NAMES OF PLANTS: *E. E.* Mesembryanthemum blandum.—*J. G.* 1, Gaultheria Shallon; 2, Thalictrum flavum; 3, Eupatorium cannabinum; 4, Solanum nigrum; 5, Amelanchier canadensis; 5, a form of Zebrina pendula; 6, Achimenes Ambrose Verschaffelt.

PEA HAULM DISEASED: *J. E. H.* The cause of the diseased condition of the Pea haulm is obscure. We expected to find Thielavia basicola, but this is not present. The only fungus found was a species of Fusarium on the stems, but this is not likely to be the primary cause of the trouble. Some cultural error, abnormal weather, or uncongenial soil may be responsible for the physiological disorder.

POTATO WITHIN A POTATO: *M. S. J.* An interesting example of a small, healthy Potato formed inside an old tuber. Such specimens are by no means rare.

SAWDUST AND STABLE MANURE: *J. G.* In the absence of manure from stables, where Bracken or peat moss is used for bedding, we should not hesitate to use manure from sawdust-bedded stables. As much of the dry sawdust as possible should be removed from the manure, but the wet sawdust should be retained, as it will have absorbed urine, which is a most valuable part of the manure. Turn the heap frequently and keep it under cover until the manure is well rotted and ready for use.

SECONDARY GROWTH IN ONIONS: *J. D.* Secondary growth in Onions is caused by moist, warm weather following a dry period, during which the ripening of the bulbs was hastened. The conditions favourable to growth caused the Onions to make a further effort, and this found expression in the division of the original bulb and the development of secondary bulbs at the base from what otherwise would have been latent buds.

TOMATOS DISEASED: *Markham* and *Anxious.* Two fungi were present on the specimens received, the chief of these being a species of Rhizopus, which enters through wounds and causes a "rip rot." The Common Mould (Penicillium) was also present, aggravating the trouble caused by the Rhizopus, but not, apparently, a first cause. Remove affected fruits to prevent the disease from spreading, and keep the atmosphere in the Tomato house as dry and buoyant as possible.

TRUFFLE OR PUFFBALL? *J. D.* The curious little fungus is not a Truffle, but a specimen of the Puffball. This is edible only when quite young and white throughout, but it does not possess the flavour of a Truffle.

NOTES FROM KEW.—IX.*

THE joys of the food producer in war time have been felt by the garden staff at Kew. Potatos (British Queen) did well on the Palace Lawn; a yield of 25 tons from about 3 acres sold for £6 per ton. There should be a larger crop next year, as the soil will be in better heart then than it is now. The drought in July checked growth somewhat, and disease made its appearance early in August. The removal of the haulms prevented the tubers from being affected appreciably, less than 5 per cent. having been thrown out as diseased or as chats.

The Onion bed in front of the Palm House (see fig. 41) has given at least as much pleasure to visitors as the flowers did in pre-war times. From the commencement of digging in April to the present time allotment gardeners and other enthusiasts have watched with evident interest the transformation of a famous flower garden plot into an Onion bed. It proceeded without mishap. A few gaps were made, partly by maggot, partly by mildew, and partly by patches of bad soil, but they were not sufficient to prevent the venture proving a decided success, as the following particulars prove:—

Area of planted ground, 2,300 yards (nearly half an acre).

Rows of Onions planted, 320.

Average number of good bulbs in a row, 75.

Average weight of bulbs, ¼ lb. each.

This estimate gives 24,000 Onions, weighing 12,000 lbs., or, roughly, 5 tons of first quality Onions. Not a bad result. The varieties grown are James's Keeping, Cranston's Excelsior, and Danvers Yellow Globe. The seeds were sown in frames in February, and the seedlings were transplanted early in April. Soot was applied twice and the plants were watered on three occasions during the early stages of growth. The soil was prepared by deep digging—the turf being put at the bottom—liming, and a dressing of 20 loads of sewage sludge and 20 loads of rotted Mushroom-bed manure. One application of superphosphate and sulphate of ammonia was given in June.

Nursery quarters and flower-beds have been used for various other vegetables. Cauliflowers, Cabbages, Turnips, and Carrots giving good returns in the early part of the year, with Parsnips, Leeks, and late Turnips to follow.

Maize is a vegetable which English gardeners have neglected. There are dwarf varieties which are as easy to manage as Cabbage, and from each plant one gets a head or cob which, when cooked and dipped in butter, is almost a meal for a man. Cooking is a simple process, being nothing more than immersing the cob in boiling water for about three minutes.

It will appear incongruous to most readers of the *Gardeners' Chronicle* that in "Notes from Kew" one should go forth at length on vegetable growing. The war has wrought many changes, some for the better; and it would be difficult to show that vegetables are outside the province of Kew. It would be easier to prove that Kew should permanently take a more active interest in British fruits and vegetables. The people are keen after knowledge of food plants and correct ways of cultivation. Why not, therefore, grow before their eyes selections of fruit, allowing them to look on and ask questions as they do now with respect to ornamentals? For every one that inquires about rubber, Cotton, Cocoa, and Cinchona, there are a hundred or more inquiries after vegetables and fruits with respect to vegetable and fruit growing.

In former days, when India and the Colonies were being set going in ways of progress and commercial prosperity, Kew had big and important work to do, and as history shows, she did it very well. They are going strong now, and there is therefore less need of Kew's assistance. But there is need of it for the development of the land resources of these islands. Hitherto we have been keen on flowers and things to look at merely. There is more important work to be done, either under the direction of the Board of Agriculture or some other influential body. In the opinion of many Kew might very well be the centre of an effort of this kind. There is Government land in the neighbourhood which could be turned to account in this direction.

The Vine pergola at Kew (see fig. 42) is a good example of its kind. It is a copy of the Rose pergola adjoining the rock garden, which was made about twenty years ago, and has given a good deal of pleasure, most of the Roses on it being happy. I have written elsewhere that the lighter in construction pergolas are, the better; and there is nothing so suitable as iron. The objection that iron injures stems that are in contact with it has no support at Kew; certainly the plants show no injuries of any kind. Iron gas-piping 1½ inch in diameter form the standards, which are kept in position at the bottom by being let into a block of rough stone, and at the top by an iron rod ¾ inch in diameter, turned at the ends and hooked into the standards. Sagging chains stretch lengthways from standard to standard. "For the greater part of the year these pergolas are unattractive, one may say they are downright ugly throughout the winter. Indeed, I have never seen a pergola in the winter in this country that was not" (&c.)

A list of the Vines on the pergola at Kew is given in the *Bulletin*, 1917, p. 90. They were planted in 1902, most of them being plants from an old collection, formerly grown on posts, where they never did themselves justice. On the pergola they are particularly happy, as the photograph here reproduced shows. "As garden ornaments they have no flower beauty to recommend them, nor, in our climate, can we expect them to bear and ripen fruit to any great extent in the open. Their value lies in the noble proportions and handsome cutting of their foliage, their vigour of growth, but above all in the richness of their autumn colouring."

This kind of structure should be useful for the cultivation of the Loganberry and other Brambles of the same character. It would also serve for Gourds grown out-of-doors. There are parts of the country, too, where the hardier varieties of the Grape vine might be successfully grown for their Grapes on a pergola such as this, and a pergola devoted entirely to Wistaria would be delightful when in flower.

Mention was made in a previous article of the African tree Lobelias in the Temperate House. One of them flowered recently, unfortunately not in a position where it could be photographed. It had an erect, leafy stem, 24 feet high, the upper 6 feet densely clothed with flowers suggesting, in pose, an Eremurus or Kniphofia, but without colour attractions, greenish, with big brown pistils. The base of the stem is quite woody; higher up it is like a Cabbage stalk, 9 inches in circumference.

The seeds were sent to Kew by Mr. J. D. Snowden, Uganda, having been collected on a mountain in Ankole at an altitude of 5,000 feet. Other species of tree Lobelia have been found on Kilimanjaro, and on Mounts Kenia and Ruwenzori in British East Africa, at altitudes of about 11,000 feet. An account of them, with illustrations, was published in *Gard. Chron.*, March, 1915, p. 125.

The plant shown in the photograph reproduced in fig. 41 is about 12 feet high, and it may flower next year. The name given to it at the herbarium is L. Giberroa, which species is described in the *Flora of Tropical Africa* as "a tall, woody monocarpic (?) plant, with the habit of a Palm, having a stout, hollow, unbranched stem 12-15 feet high, naked in the lower part

* Previous articles appeared in the issues of January 19, February 9, March 9, April 6, May 18, June 8, July 6, and August 10.

* *Clumber Plants.* Published by Messrs. J. C. & A. E. C. Jackson. Price 3s. 6d.

when in flower, densely leafy towards the top; leaves crowded, sessile, oblong-ovovate or lanceolate, 1½ 2 feet long." This fits the plant under notice, except in respect to height, the specimen that flowered here being 24 feet high. It has ripened seeds freely. This is a plant for

FIG. 41.—ONIONS IN THE FLOWER GARDEN AT KEW.

(See p. 115.)

Frost Gardens, or other places troubled by little or no frost.

Our great success under glass this year has been the Victoria Lily. It started with unusual vigour after planting on April 25, was full grown and in flower by mid June, and has produced three flowers a week, or one every other day since. Three flowers mean three new leaves per week. No plant grows so quickly as this Royal Water Lily. Nine days after a young leaf shows like a hedgehog at the crown of the plant it has expanded to full size. The largest were developed in July and August; they then measured over 7 feet across, with a turned up rim 5 inches deep. There has been no disease this year, owing, probably, to placing 3 lbs. of lime in the water three times a week as a preventive to a fungous attack which in former years was very troublesome.

The Victoria Regia will be grown as long as interest is shown in the wonders of the vegetable world. Its cousins, the tropical Nymphæas, have also made a great display, especially N. gigantea, the Australian beauty, and the Indian N. Lotus. The magnificent N. zanzibarensis no longer exists at Kew, and we have been disappointed in the Nile Queen, Nelumbium. She has made good, parasol-like leaves, but never a blossom.—W. W.

A VISIT TO CASTLE KENNEDY.

I RECENTLY paid a visit to Castle Kennedy, which in olden times was in the possession of the great Kennedy family, but has for a long period been the property of the Earls of Stair, who have gradually created its environing beauty (if we leave out the important contribution of nature to the picturesque scenes) and made it, for lovers of glades and woodlands and exquisite flower gardens, a demesne of horticultural fascination. It is fortunate for Castle Kennedy and the invariably beautiful private gardens at Lochinch Castle, that the Earl and Countess of Stair are keenly interested in horticulture, though of late years, by reason of the exactions necessitated by the war, Mr. Cruden, the gardener, has often had to make grandly grown vegetables take the place of beautiful flowers. Mr. Cruden, like his predecessor, the late Mr. Fowler, is a successful cultivator of fruits, including Grapes, Nectarines and Peaches, whilst hardly less impressive are the Apples, Plums and Pears so electively cultivated in the open, and often subjected, in our Scottish climate, to the most trying atmospheric conditions and influences. The conifers in trees at Castle Kennedy, growing on terraces between the two lakes, are justly famed, and are at present in splendid condition. I was just a little too late, at the period of my visit, to see, in the oval lake, the glorious hybrid Water Lilies, but some of the largest and loveliest of these were still flowering marvellously in that charming "basin," as it used to be termed in former days, and which is especially inspiring when it has a magnificent environment of flowering Azaleas and Rhododendrons, in June. In her attractive "wild garden" the Countess of Stair cultivates Indian and Japanese Lilies, and has splendid results with L. giganteum, specimens some years ago attaining to a height of 15 feet, with 17 flowers. At the time of my visit—though late in the season—many of the Roses and other flowers in the flower garden in front of the Castle were still flowering, with memorable artistic effect. *David R. Williamson.*

(See p. 115.)

FOREIGN CORRESPONDENCE.

DATE OF ROBERT THOMPSON'S BIRTH.

WHEN, after a long interval, Mr. Bunyard resumed his series of "Great Pomologists" with a sketch of Robert Thompson, in *Gard. Chron.*, March 23, 1918, I remarked his statement that while 1793 has generally been accepted as the year of his birth, Thompson's own account, which he quotes from the Chiswick records, gives it as 1799. This would naturally seem final authority, and on the strength of it I changed the dates on a number of catalogue cards, but happening the other day to see the obituary of Thompson in *The Journal of Horticulture*, n.s., 17, 200 (Sept. 9, 1869), I found the following: "Mr. Thompson was born at Echt, in Aberdeenshire, early in September, 1793. The precise date of his birth is not known, as at that period the birth registers of Scotland were not preserved with that care with which they are now. But from his baptism having been on the 16th day of October in the same year we may infer," etc. The same statement is repeated verbatim in the account of Thompson in *The Journal of Horticulture*, n.s., 33, 54 (July 19, 1877). The *Journal* was at that period edited by G. W. Johnson and Dr. Hogg, one of whom I suppose to have written both sketches, though I am not sure which. It is not at all unlikely that the date 1793 may have been a slip of pen or printer, but after it

had been accepted as supposedly founded on a baptismal register, it seems to me that Mr. Bunyard is rather reckless to posit the later date without explaining away the other. If this register were lost, there would be nothing to do but take 1799 as the correct date, though always, it seems to me, with a shade of doubt, but cannot someone at least ascertain whether the register still exists, and if it corroborates Thompson's own record? *M. F. Warner, Washington, D.C.*

FRUIT REGISTER.

APPLE MAIDSTONE FAVOURITE

THE Apple illustrated in fig. 43 is one of the most attractive of all early varieties, its pale creamy yellow colour and rich carmine striping, coupled with an even outline, giving the impression that it has been grown under glass. The flavour is moderately good, whilst the flesh is firm, juicy, and slightly aromatic.

It has been introduced more as a market variety than for the connoisseur, as it fills the gap between Beauty of Bath and Worcester Pearmain, and its excellent cooking qualities and firm texture make it all that an Apple should be in these respects. The variety was raised from a seed of Emperor Alexander, and its appearance suggests that the other parent was Beauty of Bath.

The raisers inform us that Maidstone Favourite having been on trial for many years it can be confidently recommended as a valuable market fruit.

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables in *Gardeners' Chronicle* for August 3, p. 42.)

Continued from p. 102.)

5. ENGLAND, S.

DORSETSHIRE.—This season is the worst known in the district, especially for Plums, but April was a very trying month, hot sun during the day and cold winds and frost on most nights. Insect pests were very prevalent. The soil is of a sandy, ironstone nature. *H. Kempshall, Abbotsbury Castle Gardens.*

HAMPSHIRE. The fruit crops in this district are much below the average; in fact, the worst I have known. All trees showed a fair amount of blossom, but the cold winds destroyed it. Strawberries yielded an average crop, but were soon over owing to the drought. Red Currants and Raspberries were very good. The soil is heavy, on a clay subsoil. *Henry Martin, Barthy Lodge, Cadnam.*

—— The fruit crops generally are very poor this season. The weather was most unfavourable at the flowering period; this affected the Plums and Apples injuriously. The caterpillar plague has been very bad throughout the district. There was a fair show of bloom. *Lewis Smith, Cadland Park Gardens, Southampton.*

—— The blossom on Apple trees this year expanded weakly, and failed to set properly. Aphis and American Blight have very greatly checked the growth of the trees. Grenadier, Lord Grosvenor, Worcester Pearmain, Mère de Ménage, and a few trees of Bramley's Seedling are the best cropping Apples this year. *E. Molyneux, Swammore Park, Bishop's Waltham.*

KENT.—Wherever a large crop of fruit was grown last year there has been an almost total failure this season, except in the case of such fruits as are gathered early, e.g., Cherries, Early Plums, and Early Apples. Pears are a total failure, except a few on walls. In the case of Cherries and Plums the severe weather when the trees were in blossom, and the intense heat of Whitsuntide, were doubtless the principal causes of failure. *E. A. Bunyard, Allington, Maidstone.*

—— The fruit crops in this district are the worst for many years. Bush fruits, however, were very good; Strawberries yielded about half a crop. The blossom on Apples, Pears, and Plums could not have looked better, but bad weather and sharp frosts in the early part of May practically destroyed these crops. *J. N. Shann, Bettshanger Park Gardens, Easter.*

—— During the forty-two years I have been here I cannot recall such a shortage of Apples, Pears, and Plums. The trees flowered well, and up to a certain point gave promise of a good crop. I noticed, however, that the petals of the Apple blossoms still remained on the embryo fruits when they should have been falling. Upon examination I found that they were attacked by weevils, with the result that the small fruit and the bloom came down together. This is a pest we have never been troubled with until this season. *J. G. Woodward, Barham Court Gardens, Teston, Maidstone.*

—— In this district the fruit crops are the worst yet recorded. The dull, damp weather in April was probably the cause of failure in certain fruits, i.e., Plums, Cherries, and Damsons. They bloomed profusely, but did not set their fruit, the majority of trees being quite bare. Pears are very scarce indeed, and Apples nearly as bad. A few varieties of Apples, chiefly early sorts, are carrying crops. Small fruits were fairly good; Strawberries looked promising at one time, but owing to continued drought during the growing season the fruits did not swell. The soil is of a heavy, retentive nature, chiefly clayey loam. *J. G. Weston, Eastwell Park Gardens, Ashford.*

—— There was a great show of blossom on Apple trees, but owing to repeated severe frosts very few fruits set. There were some exceptions, however, for Beauty of Bath, Allington Pippin, and Worcester Pearmain are bearing abundant crops. There are no Pears, and Plums are much under average. Damson trees are bearing poor crops. Gooseberries and Red Currants had crops much over the average. Black Currants, although under average, were a fair crop. Raspberries yielded a crop over the average, and the fruits were good where watering was practicable. Strawberries were average, but late varieties suffered from the drought. Loganberries yielded a particularly fine crop. *Charles E. Shea, The Elms, Poots Cray.*

MIDDLESEX. Only on one occasion before in

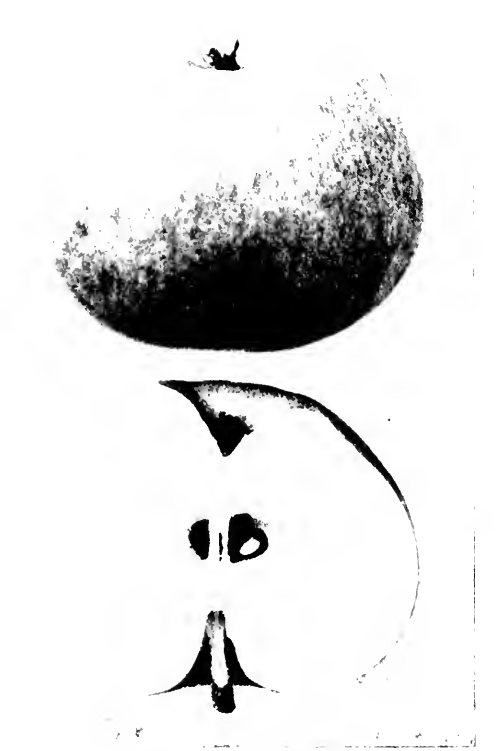

FIG. 43. APPLE MAIDSTONE FAVOURITE.

over 40 years have I had to record such poor fruit crops. Our only fair crop is that of Apples, but American Blight is somewhat troublesome. Small fruits and Strawberries were quite satisfactory. Pear trees are making healthy growth but are not over vigorous. Plum trees flowered well, but the fruits failed to swell after having set freely. Our soil is good loam resting on gravel, with London clay below. *James Hudson, Gunnersbury House Gardens, Acton.*

—— The season is remarkable for the almost complete failure of the autumn fruits. The abundance of Plum blossom gave excellent promise of fruit; the Plum orchards looked, from a distance, like sheets of snow. The scarcity of Pear blossom was striking, but not surprising after the heavy crops of last year. The uncongenial weather at the time of flowering no

doubt chiefly accounts for the absence of fruit. The soil is mainly of a light, sandy loam overlying gravel. *G. H. Head, Fulwell Park Gardens, Twickenham, S.W.*

—— This is the worst year for Apples, Pears, and Plums for many seasons. There is a fair crop of Apples Lord Grosvenor and King of the Pippins, but most of the other sorts are very scarce, including the usually prolific Keswick Codlin. Pears are almost entirely absent as a crop, although a few odd fruits occur in places. The same applies to Plums. Silver-leaf disease is becoming increasingly serious to our Plum trees. Gooseberries were a very fair crop, and for the second year in succession the bushes have been free from American Gooseberry Mildew. Red Currants have been very good, and so have Black Currants in some places. The crop of Raspberries was partially spoiled by the long spell of dry weather. *John Weathers, Park View, Isleworth.*

—— Peaches are very good this year, but Pears and Plums are failures with the exception of two trees of Gisborne Plum, both of which are bearing average crops. Strawberries were good, but Apples are patchy. Raspberries and other soft fruits were light crops. All fruit trees showed plenty of bloom, but the cold weather and the heavy fall of snow during the flowering period did much damage. The soil here is light, resting on a gravelly subsoil. *H. Markham, Wrotham Park, Barnet.*

SURREY.—Pear trees bore no blossom this year except a very few trusses on some varieties. All other fruit trees blossomed splendidly, but the weather was bad while the trees were blooming, and caused a complete failure of the Plum crop. Bush Apple trees on the highest part of the grounds are bearing splendid crops, but in other parts of the gardens Apples are a failure. The soil is very light and porous, with a subsoil of sand and gravel. *S. T. Wright, Wisley, Ripley.*

—— The Apple crop here and in the district is a failure. Most kinds flowered well, but the blossoms seemed to be very weak. The caterpillar plague was even more devastating than last year, although we made an attempt to stay the plague, both by hand-picking and washing the trees. All small fruits would have been up to the average, but were soon over, having suffered much from the drought. Pears and Peaches are complete failures; the latter trees suffered much from leaf-curl. *F. Jordan, Ford Manor Gardens, Lingfield.*

—— The fruit crops of 1918 are as bad as they could be. Cold winds and low temperatures prevailed during the flowering period of Plums and Pears; the fruits set, but all dropped in the early stages. The Apple trees enjoyed good weather while in flower, but the fruit failed to set, and the trees are badly infested with caterpillars. The dry weather adversely affected the smaller fruits; Strawberries were much below the average in size, though the flavour was excellent, and there was no waste from rot. Black Currants dropped quite half their crop before ripening owing to want of moisture. Raspberries yielded an average crop of excellent quality, but the fruit ripened prematurely. *Thomas Smith, Coombe Court Gardens, Kingston Hill.*

—— The fruit crops are most unsatisfactory. After a fair show of blossom the fruits set well, but cold winds in early spring, followed by severe attacks by insect pests, caused great losses. Lack of labour for winter spraying was undoubtedly one of the chief causes of the failure. The soil in this district is very light and sandy. *Jas Lock, Oakham Lodge Gardens, Weybridge.*

SUSSEX.—Apples, Pears, Plums and Cherries in this district are almost a failure. The few fruits on the trees are very poor in quality. Apricots, Peaches, Nectarines, and all small fruits are fairly good in crop and quality. Insect pests are very troublesome; some of the Apple and Pear trees were almost denuded of foliage, although in some cases they were sprayed three times. The soil here is very sandy. *J. W. Buckingham, Midhurst Place Gardens, Liphook.*

—— Fruit crops in general, and Apples and Pears in particular, are much below the average. Currant and Gooseberries bore average crops, but the fruits were small. Cherries were an average crop in some places. The probable causes of the failure of the fruit crop are the over crop of last year and the cold winds and hail storms in the day and the frosts at night, when the trees were in full bloom. Although caterpillars were very troublesome, I do not think they were the cause of the failure, the injury occurring before they appeared. *Leon Squibbs, Stonehurst Gardens, Ardingly.*

—— Our fruit crops are the smallest for 13 years. Bloom was profuse on Apples, Plums, and small fruits, but most of it failed to set. Insect pests, particularly caterpillars, were exceptionally numerous, and they have spoiled the quality of the few Apples found on some of the trees. Scab is also appearing on the fruit. Brown rot is very bad on some varieties of Plums, and there is a good deal of silver-leaf. Only Rivers' Early Prolific and Monarch have average crops. Raspberries were the best of the small fruits. The leaves were stripped from many Gooseberry and Currant bushes by sawfly larvæ. Strawberries yielded a good crop, but of brief duration, owing to drought. There are both heavy and light soils in the district, and crops are about the same on both, though the trees look healthier on the heavy land. *E. M. Bear, Hailsham.*

WILTSHIRE. Pears practically nil. Apples and Plums very seriously "under." Here and there may be seen a few Apple trees bearing average crops. *Thomas Sharp, Westbury, Wilts.*

—— The severe frosts experienced during April, May, and June were very destructive to nearly all kinds of fruits. *Thomas Challis, Wilton, Salisbury.*

(To be continued.)

ORCHID NOTES AND CLEANINGS.

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Potatos.—Continue to lift second early varieties of Potatos as soon as they are ready, selecting clean, well-shaped tubers for seed purposes. Allow the seed tubers to lie on the ground for a few days until they are dry, when they should be removed to a cool, well-ventilated shed and exposed fully to light and air. Gather up the large tubers and store them in a cool place or pit until the spring. Discard all tubers showing the least sign of disease.

Brussels Sprouts.—Where these plants are grown in a fully exposed situation they are liable to be damaged by strong winds. Stir the ground freely between the plants and remove all dead and decaying leaves from the stems. After the ground is cleaned draw a quantity of soil to the plants to keep them firm at the roots.

Lettuce.—Continue to put Lettuces in a cold frame in rich soil. Let the plants be fully exposed to the air until such times as they require protection from the weather. Make final sowings in cold frames to obtain seedlings for planting in frames and also for setting out of doors in the spring. Plant the latest seedlings in the open of such varieties as Brown Cos, Hick's Hardy White, and All the Year Round. Protect the plants from slugs by frequent light dustings of soot.

Endive. In many establishments Endive is in great demand, especially where it is used as a cooked vegetable. Unlike Lettuce, fully grown Endive may be kept in good condition for several weeks in various make shift positions, such as the borders of Peach houses. As fast, therefore, as available spaces are cleared of the ground Endive should take its place. Blanching should not be commenced until the plants are nearly or quite fully grown.

General Remarks.—Make preparations for protecting tender crops, such as Vegetable Marrow and French Beans, from injury by frosts, which may be expected any time after this date. Pits and frames should be got in readiness for pricking out Cauliflowers, Lettuces, and Endive, where protection may be afforded when necessary. Every advantage should be taken of fine days to remove weeds and rubbish to the garden fire. Peas and Beans that have finished bearing should be removed and the ground they occupied cleaned. A plentiful supply of dry bracken should be got in readiness for protecting vegetables in the open later.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

The Gathering of Fruit.—Early Apples may have already been gathered and stored. Some of the fruits may prove most useful for the making of jam, or for mixing with Mulberries or Blackberries. It is not necessary to take much trouble with the storing of early Apples, as the fruits will be in almost daily demand for cooking. Early dessert varieties need careful watching, as oftentimes they do not keep well. If needs be use them for cooking rather than allow them to spoil. Mid-season varieties need more care in storing, and these should be graded as they are taken into the storeroom. The most should be made of these mid season sorts to keep the later varieties in reserve for as long as possible. As the cropping this season has been variable, judgment must be exercised to make the Apple crop hold out as long as is possible. So far as can be determined at present Apples are maturing a few days earlier than usual. Do not place the fruits on hay, or even straw. A lattice wood staging is by far the best method. Keep the fruit-room well ventilated for a time, and see that mice do not gain admittance to the fruit store.

Lifting and Replanting Peaches and Nectarines.—This work, which in many soils and situations needs to be attended to every few years, should receive attention. First proceed by mixing a quantity of rich, fresh soil to take the place of that immediately surrounding the trees. If the soil be somewhat poor, mix a little well-decayed manure with it, the best that can be had; break the manure finely before mixing it with the soil. Add some old mortar rubble, or if in a district where limestone is available use that instead. Turn the compost on at least two occasions, and meanwhile keep it covered. Start first with the earliest varieties and finish with the latest; the former can be safely lifted as the true aim is ready for the work. Supply sufficient growths should be reduced as much as possible; all sub-lateral, sappy shoots should be removed. The old shreds and string should be cleared from the branches, and the tree detached from the wall. Take care that the stem is not planted at a lower level than before. Shield the border appear to be too retentive of moisture use some coarse rubble, or place a drain at the front to carry off superfluous water. Distribute the roots equally, pruning them as may be necessary. Press the border firmly and water the roots once at least, soon after the work of planting is finished. Take care that the soil of the border never becomes absolutely dry. The roots will commence to grow almost at once, and sooner than many imagine. Keep the syringe freely in use to wring, since "aphis"

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Seedlings.—Seedlings of Cattleyas and Laelio-Cattleyas raised from late-sown seed should now be far enough advanced in growth for transplanting. It is important that each one be planted separately at the earliest possible date those pricked off into a pan have to make roots before winter. Very small seedlings should be pricked off several together in well-drained pots or pans. Old pots with old soil loose to the most serious disorder. Plants at a more advanced stage may be grown in very small pots. Seedlings that have matured their first pseudo-bulbs will be starting out new roots from the base of the growth; these should be repotted in larger pots and given every encouragement to grow as quickly as possible. They will not make much growth in the winter, and will not require much water at the roots or in the atmosphere as the summer; but the must not be given any season of rest until the flowering stage is reached, but must they be allowed to become root-bound. A suitable rooting medium consists of equal parts Osmunda fibre. All fibre and Sphagnum moss, cut into short portions. Add some chopped moss and crushed crocks, and mix the whole well together. The materials should not be pressed tightly in the receptacles, as it is important that water should pass quickly away. If a house is specially devoted to seedlings of this type of Orchid, it should be kept a few degrees warmer than the one in which the older plants are grown. Should it be necessary to grow them with the older plants, they should be placed in the warmer and shadier part of the house, and near to the roof glass. Seedlings of Cypripediums should also be treated as described above, but a small quantity of fibrous loam, from which all the small particles have been removed, should be added to the compost. The soil should be pressed moderately firmly among the roots. Seedlings of more advanced growth and those nearing the flowering stage, which have filled their pots with roots, should be shifted into larger pots. These should be given a more substantial compost, consisting of at least one-third its bulk of fibrous loam. After the seedlings are rerotted they should be afforded a warm, moist atmosphere and a shady position. Water should be applied sparingly only keeping the compost just moist by frequent light sprayings. Seedling Cymbidiums should be rerotted in a similar rooting medium to that advised for Cypripediums. These plants should be kept growing actively at all seasons until they reach the flowering stage. They should occupy a position near the roof glass in a house with an intermediate temperature. Seedling Odontoglossums in various stages of growth should also receive attention at the roots. Seedlings of the current season should be transferred from the seed-pots to pans similar to those recommended for Cattleyas. Others that are more advanced may be placed three or four together in 60 size pots, and when large enough may be potted up singly. Young plants should not be potted so firmly as the older specimens. When rich moss is used slugs frequently make their appearance, and should be trapped by Lettuce leaves placed on the stage among the plants. The slugs should be sought for with a lantern after dark.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Schizanthus. When the young seedlings are large enough pot them singly into small pots and keep them growing near the glass in a cool pit. Another sowing may be made before the end of the month for later flowering. Sow the seeds thinly in pans and place them in a cool house; as they have germinated they may then be placed in a cold frame until there is danger of severe frost.

Bouvardia. Plants which were planted out of doors must now be lifted and potted. Endeavour to preserve a good ball of roots, and place them carefully in pots of suitable size. When potted the roughly soak them with water and place them in a close pit. Spray them two or three times a day, shield the pit to be bright, and keep them shaded from full sunshine until new growth is well started from the stem. They must be gradually inured to the conditions.

Coleus. [illegible] suitable time to [illegible] from cuttings. Insert the [illegible] and the cuttings in 6-inch pots, and [illegible] the propagating [illegible] The plants must be examined frequently, and the points pinched out as soon as they have developed sufficient roots. Gradually reduce the supply of water to the roots after the stage has developed. When the plants are well established they must be grown [illegible]

Ferns. [illegible] must be kept moist at the roots and [illegible] Take care to see that the fronds are not [illegible] The atmosphere must be kept dry except during the [illegible] of hot sunny days. Examine the plants frequently and remove all dead fronds.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to Mrs. DUMSDEIL, Keele Hall, Newcastle, Staffordshire.

Renovating Peaches and Nectarines. The instructions given in last week's article on renovating established Plum trees apply also to Peaches and Nectarines. The trees in the early houses will soon be ripe enough for root lifting or transplanting. In the meantime sufficient compost should be prepared, not only for the early houses but for mid-season ones also. It is most important that the work be carried out during the next few weeks, because it is essential that the trees obtain a good root hold in the fresh soil before cold weather sets in. On no account should manure or leaf mould be added to the compost, or any vegetable matter that would produce rank growth. It is better to incorporate some of the old soil with the new turf rather than make it too rich. Besides the necessary mortar or old lime rubble a sprinkling of wood ash and bone meal may be added with advantage.

Planting Young Trees. It is usually a waste of time and labour to attempt to resuscitate old and exhausted trees, when young ones of good shape and improved varieties can be bought at a reasonable price. It is a good plan to have a few young trees always on hand, of various heights and varieties, to replace failures. At this season quite large trees can be lifted and transplanted to fill any vacancies in early and summer, or late houses, but the work must be carefully carried out if they are to give a fair crop of fruit the following season. Take care that the trees are not planted any deeper than they were before removal; this can be avoided by making the bottoms of the holes firm before planting. Lightly tread the soil about the roots, giving them a slight tilt upwards, as the filling-in proceeds, to encourage fibrous roots near the surface. Give one good watering to settle the soil, syringe the trees twice daily, and apply a light shading until they are established in the fresh soil.

Making New Borders. Most soils can be adapted to the growth of Peaches and Nectarines, provided it is well drained. A good, heavy loam, at least 2 feet deep, and of a calcareous nature, requires very little preparation beyond trenching the ground and incorporating a liberal quantity of old mortar rubble and broken bricks to keep it porous. A suitable selection of Peaches for the season may be made from the following: Duke of York, Hale's Early, Peregrine, Noblesse, Dymond, Walburton Admirable, and Alexandra Noblesse. The following Nectarines are usually found suitable: Cardinal, Early Rivers, Lord Napier, Elruge, Violet Hâtive, Newton, and Victoria. When planting, spread out the roots laterally and make the soil quite firm. Give just enough water to settle the soil; as the trees are likely to sink a little, lying to the wall should be postponed for a while.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

Fuchsia. Though several kinds of Fuchsias are hardy in ordinary winters, it sometimes happens that the weather is too severe for them, and a few should therefore be propagated to meet contingencies. They may be propagated similarly to Pentstemons. I have known Fuchsia roots survive many winters, only to succumb to the first severe frost. Those of the Globosa section and F. Riccartonii are deciduous therefrom, may be lifted before the ground, but they always spring into new growth in spring. It does not usually matter as, like Romneya, Cortusa, the best results are obtained from plants that have been cut down by the frosts. It is essential to house the cuttings early in December, standing them in a frost-proof or nearly frost-proof house, and get the cuttings in February, to be planted later when rooted and sturdy.

Pentstemon. Another batch of cuttings of Pentstemons, which are now numerous on the young shoots, should be inserted in boxes, as advised in a previous calendar. Never allow the cuttings or the soil to become dry. It is perhaps not generally known that the smaller-flowered kinds, such as Pink Beauty, are hardy, or nearly so, and if left untrimmed in winter and pruned in spring, flower earlier, and continue as long in bloom as varieties of the large-flowered section, and besides grow into large specimens. I have had them here of many years' standing and of great decorative effect.

Mixed Borders. Much attention is needed to keep the mixed flower borders trim for the next few weeks, as many plants are "going off," and their absence has to be made good by arranging Michaelmas Daisies, Chrysanthemums, and others to cover them. It is much better to go very frequently over the borders, even if only a few plants need attention, than to wait until large numbers have to be seen to. This method not only saves labour but what is as important, the changes in the border are less, or very little noticeable. It will also be necessary to cut back rampant growths, which are usual at the time of year. Any seeds that are likely to be needed should be gathered at once, and should any changes be in contemplation the identity of plants and clumps must be indicated by labels

EDITORIAL NOTICE.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, SEPTEMBER 23—
National Chrysanthemum Society. Floral Committee at Essex Hall, 3 p.m.; Executive Committee at 55, Wellington Street, Covent Garden, at 6 p.m.

TUESDAY, SEPTEMBER 24—
Roy. Hort. Soc.'s Cons. meet. Vegetable Show, judging at 11.30.

SATURDAY, SEPTEMBER 28—
Finchley Chrysanthemum Society.
National Chrysanthemum Society's Exhibition of Early Chrysanthemums, in connection with Finchley Society.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 55.5°

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, September 19, 10 a.m.: Bar. 29.8; temp. 58°; Weather—Bright.

SALES FOR THE ENSUING WEEK.

WEDNESDAY
Sale of Bulbs at 67 and 68, Cheapside, London, E.C., by Protheroe & Morris, at 1 o'clock.

Insect Pests. Although written primarily for the allotment-holder, we are confident that Professor Theobald's little book describing the chief insect pests of vegetable and fruit crops will be both welcomed and used by gardeners generally. Professor Theobald's mastery of his subject is unrivalled, and is revealed, perhaps, even more strikingly in this primer than in his large and classic work, which is, or ought to be, in the hands of every fruit-grower. It is no easy task to write a great little book, yet this Professor Theobald has succeeded in doing, and for this achievement our congratulations and thanks are due. The author does not waste words in general discourse, but addresses himself, after the briefest introduction, to a description of the life-history of the pests which commonly attack garden crops. The descriptions are concise, and yet sufficient for the purpose, and are assisted considerably by the illustrations which accompany them.

The post of dishonour in this record of insect crime is rightly given to the wireworm, which is of all pests, except, perhaps, eelworm—that which does most harm to garden crops. Professor Theobald, after describing the larva and mature form, shows the cultivator how he may best combat the ravages of this pest by sowing suitable crops on infested ground—Peas, Beans, etc., in place of those, such as Potato, Turnip, and Swede, which wireworms attack voraciously. The methods of trapping and of soil treatment are also described, though we notice omission to refer to the benefits which are to be obtained by the use of soluble nitrogenous manures—such as sulphate of ammonia—applications of which are often remarkably efficacious in enabling the plant "to grow away" from the pest. The Leather Jacket, which in the present season is responsible for much of the damage erroneously attributed to wireworm, is said by Professor Theobald to be readily extirpated by such soil insecticides as naphthalene, and a good word is also said for gas-lime as a destructive agent, though, unfortunately, good gas-lime—the smell whereof we all disliked so heartily when it was plentiful—is now often hard to come by.

Among the other pests which are described with brief and skilful pen are the Turnip flea beetles, weevils of Pea and Bean, cockchafers (white grubs), cutworms, some of the chief fruit-tree pests, such as winter moth and codlin moth; fly of Onion, Carrot, Celery, Beet, and Cabbage root; sawflies, aphides, scale insects, and snow flies. Last, and, unfortunately, none too numerous, are the beneficial insects, including Ladybird Beetles, which feed on aphides and scale insects, and hence deserve every protection; the Lacewing flies, of evil smell, but whose larvae are of undoubted utility in destroying plant-lice and scale insects; and the Ichneumon flies, which so often correct the balance of Nature by acting as parasites of pests, and hence keeping down their numbers. A section on simple insecticides concludes this admirable little work, which, as we have said, should prove both useful and instructive to all gardeners, whether allotment-holders or professional cultivators. Its appearance is opportune, for this year is, we fear, likely to prove an exceptionally pestful year, and the more general a knowledge of the damage done and of the means of preventing it, the less the crops on which so much dependence is placed are likely to suffer. We would suggest that in the next edition the author adds a chapter on the birds which are enemies of insect pests.

Insect Enemies of the Allotment Holder. By Fred. V. Theobald, M.A. Pp. 59, with illustrations. Price 1s. 6d. (Published by the author, Wye Court, Wye, Kent.)

Climbing Beans at Wisley. — The Royal Horticultural Society wishes to draw attention to the extensive trial of Climbing Beans of all kinds now at their best in their gardens at Wisley, Ripley, Surrey. The high food value of these plants makes them most valuable to grow in the garden, and the Council feels that they are cultivated far too little. All types are well represented in the collections now growing there (139 stocks), and comparisons may readily be made of their habit of growth and cropping qualities. The use of the pods in the green state is, of course, well known to all, but comparatively few realise the value of many varieties, such as those of the wax-pod type, for cooking whole, the usefulness and high food value of the half-ripe seeds, and the possibility of growing Haricot Beans for storing dry and use in winter. Any variety may, in fact, be so used, but differences in yield, colour, and flavour make some more desirable than others.

Protection of British Wild Birds.—The war put a stop to the deliberations of the Departmental Committee appointed by the Home Secretary in 1913 to consider amendments to the law relating to wild birds, and its administration. It is hoped, however, when the Committee meets again, with the evidence it has already accumulated, it will be able to suggest lines upon which a new Wild Birds Protection Act may be framed. The creation of an Ornithological Bureau is suggested as an important matter for consideration.

The Clove Industry of Zanzibar. — On the authority of the United States Consul at Mombasa, we learn that 90 per cent. of the world's supply of Cloves is furnished by the plantations in the Sultanate of Zanzibar (the islands of Zanzibar and Pemba). It is estimated that 54,000 acres are devoted to the cultivation of Cloves, and that this area contains about 5,700,000 full-bearing trees. The annual average production is about 5 lbs. per tree, and the total 1915-16 crop came to 26,267,315 lbs. Nearly one-half of the crop goes to India; the next best customer is Great Britain, with the United States and France following. Two other very interesting facts appear: one is that the Clove industry—so far as cultivation and harvesting are concerned—is in the hands of Arabs, and has descended from father to son for many generations. The other fact is that efforts to establish Clove groves in other parts of Africa, where soil and conditions appear to be similar to those of Zanzibar, have failed utterly.

Control of Fertilisers in France.—A central office, under the control of the French Minister of Agriculture, has been created to deal with the supply and conservation of artificial fertilisers during the war, and for a year afterwards. The department will have power to buy, or to requisition, all artificial manures, fertilisers, fungicides, and insecticides, as well as all the materials necessary for their manufacture. Power will also be given, if necessary, to enforce the declaration, by holders of chemicals or materials, of the stocks they possess.

Canteloup and Water Melon Cultivation in the United States. The enormous extent of Melon cultivation in the Southern United States of America may be gathered from the following figures, recently published in *The American Florist*. The commercial acreage of Canteloup Melons in 1916-1917 respectively was:—Georgia, 3,139, 7,980 acres; Florida, 784, 1,065 acres; Colorado, 4,595, 5,085 acres; New Mexico, 700, 700 acres; Arizona, 2,260, 3,020 acres; Nevada, 200, 500 acres; California, 15,141, 16,059 acres. Totals, 26,819, 34,409 acres, a decrease this year of 7,590 acres, or about 22 per cent. The acreage under Water Melons in the following States for 1916 and 1917, respectively, was: Georgia, 19,995, 31,133 acres; Florida, 10,653, 21,173 acres; Alabama, 3,739, 5,767 acres; Texas, 9,230, 13,605 acres; Arizona, 200, 150 acres; Central California, 1,400, 1,665 acres. Totals, 45,217, 73,493 acres, a decrease this year of 28,276 acres, or about 39 per cent.

Georgia State Forest School.—To meet the shortage of lumbermen in the United States caused by the way in which forest students responded to the call for fighting men for the war, the Georgia State University is arranging a special one-year course of instruction in practical logging engineering. The course is divided into four terms and open to men of good character eighteen years of age, and who have a sufficiently good general education to enable them to pursue the work profitably. The practical side of the work is emphasised during the course,

but especially during the fourth term in the woods. Each branch of the work is first considered theoretically and then followed by practice in the wood and field. Every student is required to carry out each operation in logging, milling, scaling, etc., and certificates are awarded only to those who successfully complete the prescribed course at the State Forest School.

Potash from Californian Kelp.—The August issue of the *Journal of the Society of Chemical Industry* contains an account of an extensive industry near San Diego, California, where potash and acetone are produced on a large scale from the giant Kelp of the Pacific Coast. The works cover 30 acres of land, and over 1,000 men are employed. The production of acetone for the British authorities is the chief business at present, but various by-products are being developed in increasing quantities. In 1917 about 24,000 tons of Kelp were cut and dealt with each month.

Pomological Station in Brazil. The Brazilian Government has sanctioned the establishment of a Pomological Station at Deodoro, Brazil, where one tens of established varieties of fruits will be grown, new varieties and species tested, and indigenous fruits selected and improved. It is also the intention to start a school in connection with this station for students desirous of studying the pomological branch of agriculture.

Prize for Blackberry Pickers. As an incentive to increase the output of preserving the crop of Blackberries the Ministry of Food Committee is offering a silver cup to be won by the local council which produces the best record for picking this wild fruit.

Prices for Marrow Jam. By a recent Order, amending the Jam Prices No. 2 Order published on September 1, the Food Controller fixes the prices of Marrow Jam, Marrow and Lemon, Marrow and Raspberry, Marrow and Red Currant, Marrow and Elderberry, Marrow and Ginger, Marrow and Strawberry, Marrow and Blackberry jams as follows, the prices being the same as those payable for Damson and Apple and Gooseberry jams: Wholesale, 1-lb. jars, 7d.; 3-lb. jars, 2s. 4d.; 7-lb. tins, 5s. 5d. per 7 lbs., 7d. per lb. Retail, 1-lb. jars, 11d.; 2-lb. jars, 10d.; 3-lb. jars, 3s. 3d.; 7-lb. tins, 9s. 3d.

Wood for Fuel. An Order dealing with the sale and distribution of fuel wood fixes the maximum price at 30s. a ton, cash for logs considered retail in ratio value to that of coal. The Timber Order requires every person having timber to deliver it to the fuel wood which can be produced from the waste for sale at a fixed price. The distribution will come under the control of the agencies set up by the Controller of Coal Mines. The Local Fuel and Lighting Committee will be empowered to fix the maximum price for the wood. No one will be entitled to buy more than two tons of the wood in the year without a permit from the Local fuel overseer. Where fuel wood is plentiful consumers will be required to take a proportion of their allowance in wood instead of coal. It is hoped that timber will be available in all except the large industrial centres. The price will necessarily be less nearer the points where fuel wood is produced.

War Item. Lieut. C. RALPH CURTIS, only son of Mr. and Mrs. CHAS. H. CURTIS, has been wounded in the recent fighting; after being wounded he was blown some distance by the explosion of a shell, and immediately afterwards buried under the soil of what he says "was a shell." He is in hospital in France and making good progress.

ON INCREASED FOOD PRODUCTION.

A PROLIFIC POTATO CROP.

ON April 9 I planted 14 lbs. of seed tubers of Stirling Castle Potato. On August 28 the crop was lifted, and the produce weighed 4 cwt. 26lbs. The tubers were of first quality, with no disease, and only a very few small ones. This variety was introduced by Messrs. Sutton and Sons in 1914, and would seem to have a brilliant future. An allotment holder in the neighbourhood informed me that he also was lifting nearly as much per rood of the same variety.

It would be interesting to learn from readers of the *Gardeners' Chronicle* whether this is approaching the record crop for ordinary cultivation.

Hon. Sec. Allotments Committee, Lehigh Park, Reading.

MANURES.

STABLE and farmyard manure are often much too valuable on the smaller gardens, and so far no single substance has been discovered to take their place with like results.

Each has its special importance, but to be considered, (1) the richness of the soil in the three chief plant food elements, nitrogen, potash, and phosphorus, and its mechanical condition.

Where artificial manures alone are used there is a danger from two sources, first of altering the right proportion of the above substances, thus inducing other undesirable chemical conditions; and secondly, of allowing the soil to become close and inert from lack of organic matter. The latter condition will soon be apparent should the soil be of a naturally heavy nature. The full use of garden refuse as manure will do much to mitigate this, apart from the considerable amount of plant food which it contains.

All kinds of vegetable trimmings, weeds, Potato haulm (if free from disease), and anything that will decay completely, may be put on the heap, and it is a good plan to allow it to remain a season, using each year the accumulation of the previous season.

Horse soils, however, might probably benefit more if the material is applied in a half-decayed condition, provided natural lime is not lacking.

Lighter soils should receive a thorough rotted. The practice of mixing lime with the

[Photograph by E. J. Wallis.

FIG. 44.—LOBELIA GIBBEROA IN THE TEMPERATE HOUSE, KEW.

(See p. 115.)

potash as plant food. Also, we may ask ourselves whether certain kinds of refuse are of most value green, or partially or completely decayed.

The full use of vegetable matter, with a judicious and intelligent application of artificial or chemical fertilisers, may perhaps go far towards solving the difficulty of manuring.

Lime is of the utmost value: applied to a heavy soil it breaks up the clay and sets free quantities of potash. At the same time it renders available what small amount of humus is present by converting it into plant food. This, while benefiting the present crops, renders the application of organic material superative.

An old soil which has been well manured for many years will be rich in humus and inclined to acidity. Such a soil, with light dressings of lime at fairly frequent intervals, would suffice for several seasons without animal manure, and, in fact, benefit from such treatment. Afterwards, of course, organic material of some kind will again be necessary, and light applications of fertilisers containing potash and phosphates advisable. *Sydney Ashmore.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Fruit Crops in Hampshire.—The Apple crop here is very satisfactory, and quite the best I have seen this season. The varieties Newton Wonder, Lane's Prince Albert, and King of the Pippins are especially good. Pears are rather scarce with the exception of Marie Louise. Victoria Plums have been a very fair crop, but Jefferson and Gage Plums were failures. *T. Tomson, Dogmersfield Park, Winchfield, Hants.*

American Blight.—In your issue of August 30 Mr Molyneux says he does not know how the Woolly Aphis spreads so quickly. There are two ways, one on the feet of birds, the other by flying. A great many fruit growers in this country seem to be ignorant of the fact that at one stage of its life the Woolly Aphis has wings; unfortunately I cannot give the season of the year, as most of my experience of the pest has been gained in Tasmania. After travelling over England—north, south, east and west—I am surprised at the extent to which this pest has spread during the past thirty years, especially in the south, and the indifference with which the average grower seems to treat it. There are several methods by which the tops of the trees can be kept reasonably clear. The best is by spraying the trees with kerosene emulsion. Kerosene 1 gallon, soft soap 1 lb., water 2 gallons, for winter use, and 15 gallons of water to one of kerosene for summer use, though I would not recommend anyone to spray in summer, as the emulsion has to be applied with considerable force, and I always found that if the spraying was well done in winter very few insects were left alive. If only a few bush trees have to be treated the best and easiest way is to work carefully over them in winter with a brush and petrol: the latter is instant death to the pest and does not damage the trees, as so very often happens when creosote or similar remedies are applied. The later in the season this is done the better, and the application is quite safe so long as the buds are dormant. Dealing with the pest on the roots, where it does as much or more damage to the tree, is a more difficult proposition, and I do not know of anything that could be profitably used on a large scale. When only a few trees are to be treated bisulphide of carbon will kill the pest, but this method requires a special apparatus. The best way to prevent American Blight from reaching the roots is to plant trees worked on blight-proof stock—Northern Spy, for instance. The nurserymen in this country do not seem to use this stock, while in Australia all the big nurserymen use nothing else. Now a word of warning to those about to plant trees this year. Examine them carefully, both stems and roots, and if any Woolly Aphis is found on them and the district is clean burn the trees. I bought trees sufficient to plant a few acres from a nurseryman whose catalogue stated his stock was guaranteed free from disease. When I commenced to plant I found American Blight on the first bundle, so I very carefully examined the whole lot and burned every tree on which I found the pest. The attack was not a bad one, but if I had not known the pest and had planted the trees, in a few years every tree in the orchard would have been infested. *R. C., Wilts.*

"Rogues" among Potatos.—I have pleasure in replying to Mr. Cuthbertson. A new Potato produced from a tuber of Sharpe's Victor in 1905 is in my possession, but as it is not an advance on the original sort, it has remained in my use alone. It is a good quality Potato, and early, but not one of the very earliest. Improvement has taken place through careful cultivation. I have not been able to test it under forcing conditions, so I cannot speak of it in that respect. I planted Sharpe's Victor, from Potatos I had exhibited at Shrewsbury Show, in a small vegetable plot belonging to one of my children. I noticed the difference in the growth, and allowed the plant to ripen. Then I sought the opinion of others, among them Messrs. Dobbie's representative at our show, who said it was Sharpe's Express. I therefore grew it side by side with that sort, but it proved not to be Sharpe's Express. Thereupon I sought Messrs. Sutton and Sons' representative, who desired me to write to his firm. I did so, with the result after years of trial in their grounds and in my own garden, with various sorts mentioned by that firm, it could not be named as any known Potato. My object was to find out, if possible, whether the Potato produced new sorts apart from seed. Having gone so far, I wrote to Kew asking if the Potato did so, and was at once informed that it did. I was referred to Darwin's *Variation of Animals and Plants under Domestication*, at a certain chapter and page, for what I sought. From our free library I obtained the book. In Chapter XI., p. 410, Darwin states: In the common Potato (Solanum tuberosum) a single bud or eye sometimes varies and produces a new variety, or occasionally all the eyes in a tuber vary in the same manner and at the same time, so that the whole tuber assumes a new character. For instance, a single eye in a tuber of the old Forty-fold Potato, which is a purple variety, was observed to become white; this eye was cut out and planted separately, and the kind has since been largely propagated. Kemp's Potato is properly white, but a plant in Lancashire produced two tubers which were red, and two which were white; the red kind was propagated in the usual manner by eyes, and kept true to its colour, and, being found a more productive variety, soon became widely known under the name of Taylor's Forty-fold. The old Forty-fold Potato, as already stated, is a purple variety, but a plant long cultivated on the same ground produced, not, as in the case above given, a single white eye, but a whole white tuber, which has since been propagated and keeps true. Several cases have been recorded of large portions of whole rows of Potatos slightly changing their character. *S. Jackson, Shrewsbury.*

Trichinium Manglesii.—This Trichinium, of which a characteristic illustration was given in *Gard. Chron.*, August 24, fig. 81, is such a desirable greenhouse plant that it is surprising it is not more often met with. A native of the sandy districts of Australia, from whence it was introduced in 1838, it is now rarely seen outside botanic gardens. The general appearance of a flowering plant is well shown in the illustration. It is a member of the order Amarantaceæ, and the inflorescences retain their beauty a considerable time. While a temperature such as Heaths and Pelargoniums delight in is very suitable for this Trichinium, it will not conform to a rough and ready mode of treatment. A soil principally composed of loam lightened by a little well-decayed cow manure or leaf mould, and silver sand, will suit it well. Repotting should be done as soon as the flowering season is past, and in carrying this out the greater part of the old soil should be removed. The plants should be grown on a light, airy shelf in a greenhouse at all seasons. The plant may be propagated from root-cuttings taken off when potting: portions of root about an inch long should be dibbled into well-drained pots filled with sandy soil. They will root readily in a house having an intermediate temperature. *W. T.*

London and Wise's "Complete Gard'ner."—This translation of La Quintinye's work is by no means uncommon. At least seven editions of it were published, if not more. If Mr. Shelley's copy is perfect and in fair condition a fair average market price for it would be about 2s. 6d. or 3s. I find, in a recent catalogue of a leading London second-hand bookseller, the third edition offered at 9s. Another firm quotes a copy of the 7th edition at 3s. But these people are specialists, and their prices are "selling" prices. *C. H. P.*

SOCIETIES.

ROYAL HORTICULTURAL.

TRIAL OF RUNNER BEANS.

The following awards have been made by the Council of the Royal Horticultural Society to Runner Beans after trial at Wisley:—

FIRST-CLASS CERTIFICATE. *Prizewinner*, sent by Messrs. Dickson and Robinson.

AWARDS OF MERIT.—*A1*, sent by Messrs. Sutton and Sons; *Scarlet*, sent by Messrs. Sutton and Sons; **Scarlet Emperor*, sent by Messrs. J. Carter and Co.

HIGHLY COMMENDED. Best of All, sent by Messrs. Dickson and Robinson; Champion Runner, sent by Messrs. Dobbie and Co.; **Champion Scarlet*, sent by Messrs. Barr and Sons; Giant Exhibition, sent by Messrs. Dickson and Robinson; Hollington Dwarf, sent by Messrs. Barr and Sons and Messrs. Cooper, Taber and Co.; Improved Painted Lady, sent by Messrs. Sutton and Sons; Mikado, sent by Messrs. Barr and Sons; Red Giant, sent by Messrs. J. Carter and Co.; Scarlet Emperor, sent by Messrs. Sydenham, Ltd.; The Czar, sent by Messrs. R. Veitch and Son.

COMMENDED.—Best of All, sent by Messrs. Sutton and Sons.

SCOTTISH HORTICULTURAL.

SEPTEMBER 3. The monthly meeting of this association was held at 5, St. Andrew Square, Edinburgh, on this date, Mr. Robert Fife, president, in the chair. A paper was read by Mr. R. Dickson, of Messrs. Dobbie and Co., on "The Dahlia." A fine exhibit of the different types of this flower was shown by the firm. Mr. Dickson dealt mainly with the historical and evolutionary aspects of the question.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

SEPTEMBER 9. The monthly meeting of this society was held in the R.H.S. Hall on Monday, the 9th inst., Mr. Chas. H. Curtis in the chair. One member was elected. The Army Form of the late Pte. J. H. Smith was received, also the death certificate of one member, and the sum of £15 2s. 9d. was passed for payment to their respective nominees. One member was assisted from the Distress Fund. The ordinary sick pay for the month was £65 5s. 9d.; State Section, £23 12s. 6d.; and maternity benefits, £9.

ROYAL ENGLISH ARBORICULTURAL.

THE annual meetings of this society were held in London during the week ending September 14. The general meeting took place on Wednesday, the 11th inst. Lord Barnard, D.C.L., F.S.A., presided. Important alterations were made in the rules, and other steps taken to place the society more advantageously for the new duties devolving upon it in connection with the need for reafforestation.

Major G. L. Courthope, M.P., was unanimously elected president in the place of Lord Barnard, who was elected to the Council in view

* Specially fitted for market purposes.

of his exceptional service to the society during the past four years.

The Earl of Plymouth was elected vice-president.

For obvious reasons the society's meetings, which in pre-war days were held over a period of a whole week, are much fewer, but to Mr. M. C. Duchesne, the London secretary of the society, credit is due for organising a most interesting and instructive forestry meeting, and an outing to Kew Gardens was arranged for the Thursday. The members were met at the Lion Gate at 10 a.m. by Mr. W. Dallimore, of the Forestry Museum Department, Kew. One of the first objects noticed was a healthy specimen of Picea Breweriana, a new Spruce.

In passing, Mr. Dallimore called attention to Rhamnus Purshiana, an easily-grown tree, the bark of which produces a useful drug, and the wood of which is possibly as suitable for obtaining charcoal for the making of gunpowder as the better-known R. frangula.

Coming to the Larch collection, Prof. Augustine Henry, of Dublin, led a useful discussion on the relative merits of the various kinds. Larix occidentalis planted at Kew in 1831 and 1869 was held not to be comparable with the common Larch as a timber tree in this country. A peculiar feature of this Western Larch is that the cones ripen in September, and the seeds fall out immediately, being thus difficult to collect.

The Siberian Larch, a very distinct form, and narrow in habit of growth, of which the specimen inspected was planted in 1874, was also regarded as being commercially useless. In this country it usually comes into leaf early and gets damaged by frost. L. americana, bearing small golden cones, is of no better value than the Siberian Larch, but has the advantage of growing well on swampy ground.

L. kurilensis, from Northern Japan, having a Cedar-like habit, is decidedly ornamental; it was likewise voted "not useful."

Summing up, the field is still held by L. europæa (the common Larch) and L. leptolepis (the Japanese Larch), both being well-loved popular taxons as the staple British timber trees.

In the Queen's Cottage Grounds an experimental plantation of Elm was inspected, the plants being seedlings from sources which go to prove Prof. Henry's theory that species produce true progeny and hybrids produce variety.

Near this a plantation of Larix occidentalis (Western Larch), raised from seeds collected by Prof. Henry, sown in 1909 and planted in 1915—with a group of common Larch sown and planted at the same time, which proves the great superiority of the latter for this country.

Coming to the Pinus, some fine plants in the Cembra group proved to be P. armandii, being early introductions by Prof. Henry of the more recently collected species from the same source by Mr. Wilson. These plants are therefore the first and largest specimens in the country.

A good word was said for Pinus Pinaster, of which large quantities of timber are drawn in normal times from France as pitwood for the South Wales collieries. This Pine has proved a useful tree for planting in sand dunes and dry positions. Spruces in general are not a success at Kew.

One species which commanded general attention, however, was Picea Omorika, the Serbian Spruce, good plants of which were noticed; these were planted in 1891.

Near the lake some interesting forms of Abies were inspected, one fine tree being a Kew hybrid, with Abies cordifolia, a robust grower, and A. firma, the latter Hornbeam-like, and desirable as an ornamental tree.

The huge British Columbian flagstaff came in for much admiration, and considerable speculation with regard to ways and means of erecting it in position. It is 214 feet in length, 2 feet 9 inches wide at base, and 1 foot wide at the small end. The noble Douglas Fir from which the flagstaff was obtained must have been about 300 feet high when felled.

Passing the Ash collection, among which Fraxinus excelsior heterophylla, F. coriacea, and F. americana seem to be specially worth planting as decorative trees, and a very fine, well proportioned Tulip tree 65-70 feet high, a group of Poplars was inspected.

Populus Eugenei, planted in 1888, was strongly urged by Mr. Dallimore in preference to P. serotina for profitable cultivation, the habit being more erect and close branched.

Extensive cultivation of Poplar was later in the day advocated by Mr. Pratt, an ex-president, and others members as one of the most profitable trees.

Of the Birch family, Betula occidentalis was held to be a promising forest tree, while B. Maximowiczii, a Japanese Birch, is a fine ornamental subject.

EDINBURGH ALLOTMENTS FEDERATION.

A VERY successful exhibition was held on September 6 and 7 at the Synod Hall, Edinburgh. The exhibits consisted chiefly of vegetables of a useful character, and the standard of quality was excellent. The entries were numerous, and the trade was well represented. A very interesting and educative exhibit (see fig. 45) was staged by the Parks Department (superintendent, Mr. J. W. McHattie), consisting of Potatos (eighteen varieties), Peas (fourteen varieties), Cabbages (six varieties), Kidney and Runner Beans, Tomatos, and various other choice vegetables. Altogether there were 121 dishes in the exhibit, of which we give an illustration (see fig. 45). The show was opened on the first day by Sir John Lorne M'Laod, Lord Provost, and by the Secretary of State for Scotland, Mr. Munro, on the second day.

FIG. 45.—VEGETABLES FROM THE EDINBURGH PUBLIC PARKS EXHIBIT AT EDINBURGH EXHIBITION.

SOUTHEND FOOD-PRODUCTION.

SEPTEMBER 15 AND 16.—Under the auspices of the local Food Production Society, a potato exhibition was held in the High School for Boys at Southend, on the above dates. The entries exceeded those of 1917 by more than one hundred. Competition was keen in most of the classes, notably in those for collections of allotment produce, six dishes of vegetables, four dishes of vegetables, and Potatos. The list were shown to fine form, but the number of exhibits from cultivators was not so large as last year. In the class for any other vegetable than those specified in each dish classes there was but a very moderate exhibits, varying from Haricot and Butter Beans and Cornobs, to Red Cabbage and Pumpkins. The local competitions, in which allotment holders in the several districts of Southchurch, Prittlewell, Leigh, Westcliff, Thorpe Bay, Chalkwell Bay and Crowstone competed on even terms with each other, proved most interesting, and one grower, who gained a 1st prize in his district class (four kinds of vegetables), also secured the championship prize for the whole series, and a special prize offered by Mr. Arthur Sutton.

The domestic section of the exhibition was interesting and instructive, providing a feature which might well be copied in other towns. In this division prizes were offered for the best bottled fruits, for jams and other preserves, for salad dressings, and for cakes, meat pies, and bread. In every case the competitor had to place the recipe against the exhibit, and where, as with the cake, a price limit was imposed, the cost of the ingredients had to be added.

Messrs. SUTTON AND SONS provided a wonderfully fine display of vegetables, and were awarded a Gold Medal. A Silver-gilt Medal was granted to Messrs. H. CANNELL AND SONS for a score of dishes of excellent Apples. Mr. KELLING, gardener to the Southend Corporation, gained a similar award for a collection of produce grown in the Corporation Parks; the collection included fine Sea Eagle and Grosse Mignonne Peaches, excellent ridge and frame Cucumbers, and a large variety of vegetables and salads. The Royal Horticultural Society supplied a small "Food Production" exhibit with a representative in charge, who answered a great variety of questions on gardening; and the Food Production Department sent a lady demonstrator, who made canning, bottling, and drying fruits and vegetables appear the simplest of processes.

BRENTFORD ALLOTMENTS.

IN 1917 the Brentford Allotment Association held a capital exhibition of vegetables. The exhibits were judged by professional judges, but not one penny of prize money was offered. This year, on the 7th inst., the second show was held in the Rothschild Schools, and modest prizes were offered. There were about 200 entries, and their arrangement in the show was evidence of excellent organisation, while the staging of the exhibits was far in advance of what is common at local displays. Potatos were splendid, notably the collections of six and four dishes; the first prize six dishes would have been difficult to beat at a R.H.S. vegetable show. The collections of produce from any one allotment proved interesting and educational; indeed, the educational value of the exhibition was kept in view always, and in very many instances the labels conveyed not only the varietal name of the vegetable, but the date of sowing or planting, source of supply, and other points of value.

The Royal Horticultural Society sent models of insect pests, of digging and trenching, together with photographs and lantern slides showing various items of garden work. The pig-keeping section of the Association showed two pigs killed and cut up ready for distribution among the members.

TRADE NOTE.

GOLDEN WEDDING OF MR. AND MRS. F. GEE.

ON the 9th inst., Mr. and Mrs. Frederick Gee celebrated their golden wedding at Riverford, Biggleswade. Mr. F. Gee, a well-known seedsman, is now in his 75th year, and still takes a great interest in the business he has done so much to build up, and also in public affairs. The golden wedding celebration was attended by members of the family and many friends. Congratulations were received from many parts of the world, including several from younger relatives on active service. The Biggleswade Urban District Council sent a special congratulatory resolution; Mr. Gee was chairman of this body in 1911-1914, and he is a J.P. of the County of Bedford.

CROPS AND STOCK ON THE HOME FARM.

PREPARING FOR WHEAT.

WHEAT has this season been so generally successful, and is regarded as the most essential of all crops on the farm for the needs of the nation, apart from its value to the grower, that an extra area is certain to be devoted to this cereal in the coming season. Somewhat tardily the Government has fixed the price of Wheat for the year, but from various points of view they have not done so well as they might. The price commences at 75s. 6d. per qr. of 504 lbs., and continues at this rate until January, 1919, when it will be 76s. The following April the price will be 78s. 6d., and that value will continue until June. Thus we get two sixpenny advances for the whole season. What incentive is there for the farmer under this prospect to hold any Wheat whatever? Some unthinking person may perhaps say, "why should he keep it to increase the price?" The answer is not that he wishes to increase the price, but anyone can see how little English Wheat there will be in April and May of next year. What with the loss from rats and mice, and other causes, there can be no individual gain by attempting to hold any of this crop.

For the security of a greater yield in the spring the prices should have started a trifle less and advanced up to, say, 80s. per qr.

I would advise those who contemplate ploughing grass land not to plough too soon, either for Wheat, Oats, or Barley.

In the ordinary way of cropping arable land there are several good preparations for the Wheat crop. Sheep fed Rape, or Rape and Turnips is an excellent plan, as is Mustard growing 2 feet high, ploughed into the soil and firmly pressed; this latter plan answers well where sheep are not kept, or where manure is scarce. Pure Clover has been regarded for ages as the ideal Wheat preparation, owing to the fact that Clover, being a leguminous plant, appropriates nitrogenous food from the air by the agency of nitrifying bacteria, and therefore leaves the soil rich in this plant food. In stiff soil I prefer to sow Oats in spring, as I find there is too often a loss of plant during the winter months should there be continued rains, owing mainly to the fact that surplus water from heavy rains does not percolate freely through the press marks in each furrow. With Oats sown on this land in February or March there is less risk.

Summer fallowing is an old method of Wheat culture, and a successful one, having the merit of not only exposing the soil so that it becomes aërated, but of cleansing it thoroughly from weeds and Couch grass. With thorough cultivation and the addition of 15 to 20 tons of manure per acre, no better preparation can be suggested. A crop of Potatos provides an excellent preparation for Wheat, mainly owing to some of the manure used for the Potatos remaining in the soil. Peas, Beans and Vetches are also good crops to precede Wheat, all being members of the leguminous family. A crop of Mangolds preceding Wheat gives the most variable results, mainly owing to the late date of removing the roots, thus delaying the sowing of the Wheat until the middle or even the end of November.

Basic slag will in the future play an important part in the growing of Wheat, especially where sheep are not kept. I have this season seen some remarkable results in the Wheat crop from the use of basic slag. In one 40 acre field, where the soil is sandy loam overlying clay, to satisfy some sceptics one breadth of the distributor was sown with Wheat without the dressing of basic slag. In that area the crop was not worth gathering, while in the field generally, which was dressed with basic slag, the produce was 40 bushels per acre, with good ears and stiff straw. I intend to use this fertiliser for the Wheat crop largely, at the rate of 6 cwt. per acre. I shall distribute the basic slag at the time of sowing the Wheat, harrowing it in previously when preparing the soil for drilling or broadcast sowing the Wheat.

Of all details in the cultivation of Wheat, none is more important than early sowing, and from the third week in September until the end of October is the best time to sow. *E. Molyneux.*

Obituary.

Mademoiselle Caroline Blancard.—The death of this lady, on the 23rd ult., removes from the horticultural world a link with the past. She was the granddaughter of Captain Blancard, who in 1789 introduced the first large flowering Chrysanthemums into Europe from the Far East. She lived for many years in England, and only returned to France shortly before the war. She was in her 80th year, and is survived by her sister, Mademoiselle Augusta Blancard, who is now the only bearer of this most illustrious name in horticulture, and to whom we offer our sympathy in the loss she has sustained.

Madame René Momméja. We very much regret to learn of the death of this lady on the 27th ult. Her husband, a well-known and enthusiastic amateur and cultivator of the Chrysanthemum, has been for many years a successful exhibitor at the Paris shows. He has also done excellent work as a contributor to the Press on the literary and historical aspects of the flower. His article, reprinted in separate form, entitled "Le Chrysanthème au Japon," which originally appeared in the *Journal of the Société Franco-Japonaise*, will be long treasured by those who are interested in the Chrysanthemum.

Answers to Correspondents.

APRICOTS AND GRAPES: *L. B. M.* Long neglected fruit trees trained to walls can seldom be brought into good condition under less than two or three years' careful management. Whole branches should be cut out and the rest retrained, and at the same time all basal growths by which room can be found must be used to form the basis of new branches. Give the ground a good dressing of lime or crushed mortar rubble. Advice concerning the methods to be followed to preserve Grapes from cracking will be found on p. 114.

ASH FROM OAK WOOD FIRE: *J. R.* The ash from wood fires is rich in potash, and therefore valuable as a manure, and especially now that large sources of potash fertilisers are closed. The ash should be kept dry until required for use, as it loses much of its value if exposed to rain. In potting mixtures a 5-inch potful of ash to a bushel of soil will suffice for most plants. About 5 oz. per yard run, given at planting time sets Potatos. Half a pound to the square yard is a safe allowance when preparing beds for sowing or planting Onions is a good dressing. All parts which produce sugar or starch in roots or fruits need liberal supplies of potash. Heavy soils are generally fairly rich in potash when newly brought into cultivation.

AZALEA SPECIES TO GET: *L. G. P.* No doubt this Japanese species would be quite hardy in your Dorsetshire garden, especially in a sheltered position. It needs a slightly warmer climate than that of Kew.

BLANCHING CELERY: *J. J.* If the special paper collars sold for blanching Celery cannot be obtained, a good substitute may be found in stout brown paper. If this is used in the manner described on p. 105 the soil mixed with the sets to kill slugs will not come into direct contact with the plant stalks. Sawdust would not be a suitable material for moulding up Celery as it sets closely when wet, and fungus growth frequently appears in it.

DISEASED POTATOS: *B. R.* Send specimens of the diseased tubers for examination.

GREEN WORM: *S.* If you will forward specimens of the "green worm" we will do our best to identify it and advise you as to methods of effective eradication.

NAMES OF FRUITS: *In the naming of fruits, we desire to oblige our correspondents as far as we can, but the task would become too costly and too time consuming were there no restrictions. Correspondents should observe the rule that* NOT MORE THAN SIX VARIETIES *be sent at any one time. The specimens must be good ones; if two of each variety are sent, identification will be easier. The fruits should be just approaching ripeness, and they should be properly numbered, and carefully packed in strong boxes; cardboard is often smashed in the post. A leaf or shoot of each variety is helpful, and in the case of Plums, Peaches and Nectarines, absolutely essential. In sending Plums, Peaches and Nectarines it should be stated whether they have been grown in a warm or cool house, on walls in the open, or entirely exposed out-of-doors. In all cases it is necessary to know the district from which the fruits are sent. By neglecting these precautions, correspondents add greatly to our labour and run the risk of increased delay and incorrect determination. We do not undertake to send answers through the post, or to return fruits. Fruits and flowering plants must not be sent in the same box. Delay in any case is unavoidable.*

NAMES OF FRUITS: *W. P.* 1, Probably White Transparent; 2 and 3, Worcester Pearmain; 4, Queen; 5, Bismarck.

NAMES OF PLANTS: *T. C.* The yellow-flowered annual is Tagetes patula; the red flower is Lychnis Flos-Jovis, a herbaceous plant; the white flower is probably a Clarkia, but it was received in poor condition for identification.—*A. H.* The double form of Saponaria officinalis.—*W. and S.* Bryophyllum crenatum.—*Elsie Cox.* Chimonanthus fragrans.—*J. K., Oswestry.* 1, Eryngium Oliverianum; 2, Phygelius capensis (Cape Figwort); 3, Senecio tanguticus; 4, Echinops Ritro var. ruthenicus (Russian Blue Globe Thistle); 5, Malva crispa; 6, Fuchsia gracilis.—*B. G.* 1, Diervilla (Weigela) florida var. Looymansii aurea; 2, Polygonum cuspidatum; 3, Clethra alnifolia; 4, Veronica salicifolia; 5, Levcesteria formosa; 6, Cydonia japonica.—*Onion Grower.* The plant which came up in your Onion bed is Bulbine annua, a native of South Africa. The species has been grown more or less in this country for many years, but chiefly in botanic gardens, as its ornamental value is but small. In your case it may have come directly from South Africa, just as American seeds come amongst food seeds (Beans) or amongst poultry food.

PEARS WITH CORRUGATED SURFACE: *B. and W.* We can find no trace of any parasitic organism in the Pears sent. The curious corrugations are due, we believe, to hail, which fell during an early stage in the growth of the fruits and damaged the skin and underlying cell tissue, so that development became uneven.

PRUNING CYDONIAS: *T. W.* The varieties of Cydonia japonica readily adapt themselves to pruning, which should be done in the summer. It is probable that the position your plants occupy is not sufficiently sheltered and sunny to ensure freedom of flowering.

PRUNING SWEET BRIAR HEDGE: *J. R.* If you were to prune the Sweet Briar hedge back to 3 feet from the ground in March the new growth would proceed chiefly from the upper part of the stems, and the base would remain more or less bare. A better plan would be to cut out superfluous growth as soon as the leaves have fallen and bend the principal remaining growths so that they may be pegged down at the base of the hedge, with their points trained upward beyond the peg. By this means you would be able to reduce the hedge to the desired height and obtain a well-furnished base next season.

WORMS IN BOWLING GREEN: *P. P. G.* Water the bowling green with a solution made by dissolving 2 oz. of corrosive sublimate in 15 gallons of water. This will cause the worms to come to the surface, where they can be swept up; as the corrosive sublimate is very poisonous the worms should be burned or otherwise disposed of at once, because if birds eat them they will be poisoned. Lime-water, made by mixing a peck of fresh quicklime in 40 gallons of water and allowing it to stand until clear, is also useful, as a copious watering with the clear liquid will cause the worms to come to the surface, from whence they can be gathered and fed to poultry without harm.

NOMENCLATURE OF BEANS.

ON the "Carte du Jour" [illegible] Fageolets" or "Haricots Fageolets" on shows that fresh, unripe, shelled Beans will be served; on the other hand, if simply "Haricots," or more usually "Haricots verts" is inscribed, one will get the whole young green pods, which are occasionally put down as "Aguilles" or "Filets." Sometimes, just as in this country "Runner" Beans may be specified on the menu, one meets with more exact names; for instance, in Caen my first meeting with the variety was announced on the menu with its name "Prédomes de Caen." When the term Haricots flageolets is met with it may be that the variety will be the "Haricot flageolet de Laon," which is further dealt with below, but of this there is no certainty, for so many varieties have now been established, and Haricots Flageolets blancs, verts, jaunes, rouges, et noirs (white, green, yellow, red and black) are listed by the seedsmen. In this country the practice of shelling out Beans in the fresh state is comparatively unknown, but I venture to think that it should be popularised, especially in these times, for the food value is not only high in actual substance, but also it probably partakes of the nature of a "green vegetable." In this state, we have no name for the vegetable in our language, and it seems quite advisable to take over the French word—luckily one that is fairly well pronounceable by the British mouth. Before leaving the cookery aspect, I may note that Escoffier (*Le Guide Culinaire*, 1912) is very insistent that if Parsley be used at all with these Beans it should be absolutely fresh.

From the gardener's point of view it is seen that the grouping of the varieties of *Phaseolus vulgaris* (French or Kidney Beans) is determined into two classes, (a) the all-edible "Mange tout" or membrane-free "sans Parchemin," in which the whole pod is eatable up to the full development of the seeds, and (b) Beans for shelling "à écosser" or with membrane development "à parchemin," which can only be eaten in pod form in an early stage of their growth, owing to the hard layer which soon forms, after which they can only be used as "flageolets," or allowed to ripen, when they come under the not very distinctive English title of Haricots (Haricots secs). A further sub-division of each group is made according to whether the variety is climbing ("à rames") or dwarf ("nain"). To whom may be due this grouping, or when it was introduced, I do not know, but Vilmorin, Vercier, and a number of catalogues of French seed firms have adopted it: to me it seems a useful and important practical scheme. Looking through the lists it is seen that very many of the shelling-out varieties are listed as Haricots Flageolets; on the other hand, none of the "eat-all" groups are thus designated. Excepting the waxpods, so far as my small experience goes, for I have transferred my favour for Bean seeds to the Continent, the majority of the varieties offered by our seedsmen are of the membranous type, and, moreover, dark-seeded (e.g., Canadian Wonder). For a shelling-out Bean I prefer a pale-seeded variety, and for whole pods or "mangetout" or "Snap Beans," I believe, in the U.S.A. one that does not become membranous. It is, perhaps, from the habit of growing these membranous Beans that the English cook will persist in cutting them up before cooking, whereby both flavour and food value are reduced. The ambition to be able to recognise the variety of Bean on the table by its flavour gets limited to the knowledge of the sorts that we grow, for at friends' houses the Beans are usually cut up, and the distinctive flavours evaporated.

ETYMOLOGY.—The words Haricot and Flageolet were both born in mystery. "Haricot" was not in use till the 17th century (Littré); old spelling Herigot and more antique Haligot; and probably at first appeared as Fève de Haricot (contradistinguished to Fève de Marais (Broad Bean (*Dict. Lend Fr. VI. Edn.*, Littré says the question then arises whether "Haricot" may not have given the name to "Haricot" (vegetable) or vice versâ, and the evidence of old authors is that the vegetable got its name from the stew, perhaps because the Bean was good to stew with neither or more likely because its appearance was likened to the small pieces of mutton in a "Haricot"; this rather suggests that the original Haricot would have been a red or brown coloured Bean. The following recipe given by Cotgrave (1650), and evidently a translation from an older writer (Ménagier II. V., 14th Century v. Littré), is perhaps worth quoting:

> HAVIGOT. Mutton, or other flesh, chopped small, and boyled with Onions, Parsley, Sage, Time, Hyssop, Savory, Margerom, Rosemary, Pepper, Cloves, Mace, Cinnamon, Ginger, Grains, Saffron, Salt, Verjuice, and Vinegar, and served up with the same broth, and (sometimes) chopped Eggs.

A Beane was that Fabve in French, and French or Romane Beanes were Febves pointes (perhaps Scarlet Runners or Haricots d'Espagne from the spotted or streaked seeds). Febves de Beane, and Fisedes. This last word introduces us to Flageolet. As applied to Beans this does not appear in Cotgrave 1650, or Cotgrave (1705). Thompson whose work is much tinctured by French (1659) gives it as synonym for Early Laon Dwarf Bean, of which the seed is "white, oblong, and neat"; [illegible] Vilmorin (3rd Ed. 1904) (Haricot flageolet blanc) says they are "assez petits, délicats et forme de rognon"; the earlier description perhaps may have owed its name to being somewhat cylindrical and flutelike, though Littré's derivation is from Phaseolus, with the evidence of the Provincialisms Gôney, fajole, fajule; Lyonnaise: Cambuzat, fageole; Faucigny, fajon, fajole; in a word, a corruption of "fageolet," the diminutive of "fagot." Littré (1877), like Thompson (1659), gives it as a special variety of Bean, known also as "nain hâtif de Laon," one of the most esteemed and most commonly grown about Paris. Since then, combined as "Haricot flageolet," it has been applied to a considerable number of varieties, both dwarf and tall, and irrespective of the colour or form of the seeds. Lastly, it may be noted that "Haricots" is applicable to the plant to the seeds, and, as "Haricots verts" to the green pods (Littré).

Mr. Elwes has mistaken my meaning in that shallow planting of the seeds should be restricted to white sorts; I merely mentioned the white sorts in regard to the greening of the cotyledons because the colour shows up well; darker varieties also green early if exposed to the light. The point is, that if early exposure to light is obtained the cotyledons are able to develop chlorophyll early and promote the vigour of the young plant. In regard to his difficulty with ripening, I should suggest that he should confine his attention to early, or forcing sorts, or start the plants in frames and plant out, which may be done with many sorts. Prédome is rather late in podding, but though Thompson (1659) remarks that the tall variety is not well adapted for the climate of Britain, this is certainly not my experience with the dwarf variety: last year we ripened many pounds of seed.

TOW GAY.—Besides the forms of green pods, shelled out immature Beans or flageolets and the dried ripe Beans or "Haricots" (Haricots secs), in the East I met with another mode of utilising Beans called Tow Gay in Malay "Tow" as in "how"), which is a further development of the advice given in *Gard. Chron.*, Aug. 24 1918, p. 75), to soak dried Beans for 12 hours in water. According to many authorities water should be free from hardness, preferably rain-water or water to which a tiny pinch of carbonate of soda has been added, just enough to make a bond with the dissolved lime.

"Tow Gay" is apparently prepared from the seeds of the Mung Bean (P. mungo, syn. P. aureus L. f. (in of the Chinese), and also the Adzuki (P. angularis) of the Japanese. I am endeavouring to obtain further information concerning the varieties, but it will be easy to try some of those which are cultivated in this country.

In case some may like to try this mode of obtaining a fresh vegetable any time during the winter," the following notes may be of service.

The seeds are put thickly in waterproof saucers and covered with about ½ inch of water and kept in a warmish place; when the shoots are about 3 inches long they are thoroughly washed in a strong flow of water, whereby the skins of the seeds are washed away. The sprouts are then either cooked in salted water, drained, and flavoured with sauce (or gravy?), or they may be cooked in a fireproof vessel with oil or fat, and then seasoned with ketchup, yolk of egg, etc.

As I remember, Tow Gay was a very favourite dish, and trials with some of our varieties may be worth while; my idea is to begin with Prédome, and if not satisfactory to try others. D. Bois relates that the Adzuki ripened all its seeds in Savoy, and Piper mentions varieties that ripened in 80 to 100 days in Virginia. Apparently a prize was offered in France for the best hectare of one of this class of Bean. *H. E. Durham.*

ORCHID NOTES AND GLEANINGS.

BRASSO CATTLEYA MIRANDA.

A FLOWER of a very pretty and distinct kind the result of crossing Cattleya Iris (bi- [illegible] Dowiana aurea) with Brasso Cattleya Mrs. J. Leemann (B. Digbyana × C. Dowiana aurea), sent by Frederick J. Hanbury, Esq., Brickhurst, East Grinstead, in whose gardens the plant has flowered for the first time. It proves to be a very desirable new hybrid and in colour and the firm texture of its fragrant flowers a well-defined departure from the ordinary class of hybrid Brasso Cattleyas. The sepals and petals extend over 6 inches, the latter being 2 inches wide; both the sepals and petals are bright canary-yellow, the middle of the inner halves changing to primrose-colour. The broad lip, which shows no indication of constriction in the middle, as in *C. bicolor* and *C. Iris*,

...y fully expanded, the front crimped and fringed and bright magenta rose in colour. The central area is bronzy-orange intersected by chrome yellow lines running from the base. The column is white and not so fleshy as in C. Iris.

MONTBRETIAS FROM EARLHAM HALL, NORWICH.

At the meeting of the Royal Horticultural Society held on August 27 last the group of Mont Morris, and his gardener, Mr. George Henley, deserve heartiest congratulations.

It is only fair to record the fact that Mr. Morris commenced his work of selection with an excellent foundation prepared by Mr. G. Davison, gardener to Col. Petre, Westwick House, Norwich. From some of the choicest Westwick varieties, presented about ten years ago, Mr. Morris and Mr. Henley have raised a very fine strain, and no fewer than seven of the varieties have received Awards of Merit from the Royal Horticultural Society.

FIG. 96.—MONTBRETIA "CAMEO": COLOUR GOLDEN YELLOW WITH RED-BROWN ZONE.

...ordes exhibited by S. Morris, Esq., Earlham Hall, Norwich, was the chief feature of the exhibition. The gorgeous colouring of the flowers, and the elegance of the spikes commanded general admiration. Most of the varieties were home-raised and represented a strain which appears to carry more expanded flowers at a time than is usual. This interesting feature was particularly marked in the varieties Queen Mary, Queen of Spain, Citronella, and Nimbus (see fig. 96), but it was not so evident in the larger flowered forms, such as King Henry VIII. As raisers and as growers of Montbretias, Mr.

TREES AND SHRUBS.

ABIES GRANDIS.

ABIES GRANDIS is supposed to be the tallest Silver Fir in the world, as it makes a tree of 230 to 300 feet high in its native habitat, in Western North America. It evidently thrives in this country, judging from a young tree which I recently saw in the grounds of J. H. Bowman, Esq., Greetham Common, Newbury. This tree was 40 feet high, and had only been planted 15 years, so that the average rate of growth a year, during that period, has been considerably over 2½ feet. It stands in a paddock, in grass, considerably below the level of the adjoining common, where the ground must be fairly rich and moist, but has, doubtless, a gravelly subsoil. The tree is pyramidal in habit and perfect in every respect. The leaves are of a dark glossy-green, arranged in two closely imbricating ranks on either side of the twigs, which have a rather massive appearance on account of the length of the leaves. These are almost as long as those of A. lowiana, but have no stomata on the upper surface as in that species, and that fact may help to account for their rich green colour. *J. F.*

HYBRID SUNFLOWERS.

IN a letter to *Nature*, Prof. T. D. A. Cockerell, of the Colorado University, Boulder, Colorado, U.S.A., writes:—

In crossing the different species and varieties of Helianthus some peculiar results have been obtained. The crosses referred to have all been made by my wife at Boulder, Colorado, and the results may be classified as follows:—

(1) The varieties of Helianthus annuus (including H. lenticularis, regarded by some botanists as a distinct species), when crossed together, produce plants which are as fertile as the parents. In some of the mongrel varieties there is, however, a marked deficiency of pollen.

(2) The annual species of Sunflowers (typical Helianthus), crossed together, are quite fertile, but the hybrids are themselves nearly sterile. H. annuus has been crossed with three species, H. argophyllus, H. petiolaris, and H. cucumeritolius.

(3) The annual species can rarely be crossed with the perennial, but when this occurs the offspring closely resemble one or the other parent species. One such hybrid was recorded in the *Standard Cyclopedia of Horticulture* (Vol. VI., 1917, p. 3284) as between H. pumilis and H. annuus. Renewed study of the living plants this year convinces me that this is an error: the perennial parent was, in fact, H. subrhomboideus. Both species occur here, and Mrs. Cockerell, at the time of making the cross, did not distinguish between them. Morphologically they are especially distinguished by the fact that H. subrhomboideus has underground migratory branches, by means of which it spreads, while H. pumilis is strictly stationary, reproducing only by seed. The hybrid closely resembles H. subrhomboideus (though this was the pollen parent), but is much larger, with larger broad leaves. It has small or short underground branches, but, nevertheless, is stationary. That is to say, the migrators are present, but the plant does not spread by them in all directions as do the true migratory forms. Comparing the details of structure, I found that the ray-florets of the hybrid were quite without pistils, whereas those were well developed (though not functional) in the H. subrhomboideus. However, further investigation showed, to my surprise, that some heads of the wild H. subrhomboideus had the ray-florets wholly without pistils. The involucral bracts of the hybrid are more distinctly pointed than those of H. subrhomboideus. In other cases attempts to cross annuals with perennials have resulted in total failures, as has happened when crossing H. annuus on H. pumilis, in attempts to repeat the cross described above, which was erroneously interpreted. In other cases seeds were obtained from the pollen of perennials used on annuals, and the resulting plants were indistinguishable from the annual parent. Seeds received from Mr. L. Sutton, from England, representing the F. of a cross between the red H. annuus and the perennial H. rigidus, also gave plants entirely of the annuus type.

Babcock and Clausen, in their recent (1918) admirable work, *Genetics in Relation to Agri-*

culture, have (Chap. xii.) discussed those remarkable cases in which the F_2 generation of a cross gives plants resembling the original species crossed, with greater or less fertility. A very ingenious and plausible explanation is given. Collins and Kempton recently found that in crossing two distinct genera of grasses, Tripsacum and Euchlaena, they obtained plants agreeing with the pollen parent, the Euchlaena. They call this patrogenesis (*Journal of Heredity*, Vol. VII., No. 3, 1916). One of the explanations offered by them is that the male nucleus may have developed in the ovary to the complete exclusion of the female, "representing in a way the counterpart of parthenogenesis." It appears quite possible that in some hybrids, and perhaps other heterozygous forms, particular pairs of homologous determiners do not both function or develop, so that in respect to certain characters the organism is simplex, not in the sense of the old "presence and absence theory," but in the sense of not being a hybrid at all in respect to particular features.

FLORISTS' FLOWERS.

PERPETUAL FLOWERING CARNATIONS IN UNHEATED GREENHOUSES

It is a common idea that Perpetual flowering Carnations must have fire-heat during the winter months to protect them from frosts, but this has been proved entirely wrong. Artificial heat is not necessary, and the amount of frost we get in this country will not harm the plants—in fact, many amateurs declare that their plants produce the best results during the spring and early summer if frozen during the winter.

There is no other subject so adaptable for a cold greenhouse, and no plant will produce such generous supplies of bloom during the entire twelve months of the year as the Perpetual (Tree) Carnation when grown without artificial heat. The one great essential is a free circulation of air at all seasons; even in the case of an intensely cold, frosty night, the greenhouse should be ventilated. If the plants are kept hardy they are fortified against frost; furthermore, they are not attacked by any of the common Carnation diseases, which are invariably induced by insufficient ventilation in heated greenhouses. Naturally watering must be done with discretion, and the morning of bright, sunny days is the best time to use the water can, but the plants should be kept moderately dry at the root during very wet or cold weather.

At times such as these the usefulness of flowers is multiplied. Many of us prefer not to grow them for our own pleasure, but produce them for the enjoyment of others, particularly those who have been in the forefront of our country's fight, and the healing influence of flowers, particularly during the dull season, is perhaps only second to that of the doctors and nurses, so that those amongst us who have greenhouses should see that they "do their bit" in this direction. *A. H.*

THE ROCK GARDEN.

STACHYS BETONICA VAR. ALBA

One of the most beautiful rockery plants I know—if, indeed, it should be grown on a rockery—is a dwarf, white-flowered variety of S. Betonica (see fig. 47) which I collected myself at The Lizard some years ago. Its height when passing into fruit is only 5 to 7 inches, and, with a closely-arranged mass of inflorescences, as shown in the illustration, it is both neat and effective. Stachys Betonica is a well-known British plant, and it is of interest to recall that formerly it was regarded as very important in medicine. An old proverb says "Sell your coat and buy Betony," by which it is intended to express the high admiration in which our forefathers held this plant. "He has as many virtues as Betony," is the saying of a Spaniard with whom the herb was in great repute. Antonius Musa, physician to the Emperor Augustus, filled a whole volume enumerating the many virtues of the plant, and it is said to have cured forty-seven different disorders. It was used for gout, for headaches, and was regarded as "most fitting to be kept in a man's house both in syrup, conserve, oyl, ointment, and plaister." In a modern book of Materia Medica the plant is described as feebly aromatic and astringent, but its use in dyspepsia, chronic rheumatism, and one or two other complaints, does seem to be recognised, though it is not official. In addition to its great medicinal virtues Betony was supposed to be endowed with great power against evil spirits, sanctifying, as Erasmus tells us, those that carry it about with them. The beauty of this white form attracts attention and is admired by everyone. The cultivation of the plant is of the simplest, and propagation by division is very easily effected. *E. Irwin Lynch, Botanic Garden, Cambridge.*

FIG. 47.—STACHYS BETONICA ALBA IN THE BOTANIC GARDEN, CAMBRIDGE.

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

See Tables in *Gardeners' Chronicle* for August 3, p. 42.)

(*Continued from p.* 112)

ENGLAND: N.W.

Westmorland.—The blossom on Apples and Pears this year gave abundant promise of a crop, but the flowers faded at once under the destructive influence of the east winds and a plague of caterpillars. Spraying did no good, and hand-picking was only possible on low-growing trees. Apples, therefore, are scarce and there are none Pears. Plums, especially Victorias, are good on some trees. Small fruits are poor. I saw on the 4th inst. trees of Damson Merryweather were covered with bloom, and the fruit set well. *W. J. Miller, Lowther Gardens, Kirkby Lonsdale.*

ENGLAND: S.W.

Cornwall.—The fruit crops are the worst on record. Pears are a complete failure, and so, with very few exceptions, are Apples. Peaches are rather better than was at first expected, but the crop is only half the average. Plums and Morello Cherries are scarce. Strawberries yielded a small crop, the latest varieties being the best. The only full crops were Gooseberries and Raspberries, which were very good. Our soil is on rock, and moisture drains away quickly. *Wm. Andrews, Trewithian Gardens, Truro.*

Devonshire.—This is the worst season for general fruit crops that I remember during twelve years' charge of these gardens. The only varieties of Apples cropping freely are Lord Grosvenor and others of the Codlin family. Scores of trees are not carrying a single fruit, notwithstanding that there was a fair amount of bloom on most varieties. Pears are a complete failure, and the same is true of Plums. Silver-leaf disease has been very prevalent during three past seasons. Victoria suffering badly in this respect. American blight is also making rapid headway in this part of Devon. *F. H. Bolton, Powderham Gardens, Exeter.*

—It is many years since there has been such poor crops generally. There has been an abundance of insect pests. *P. C. M. Veitch, Rood Nurseries, Exeter.*

Gloucestershire.—The fruit crop in this part of the country is a very light one indeed. When the trees were in bloom everything seemed to promise a very heavy crop again this year, but the severe frosts in May, followed by very much bright, dry weather, destroyed all prospects of any crop of fruit. We have no Pears excepting a few Perry Pears. Our soil varies in this district; some is a very heavy loam or clay, other places quite near are light and sandy, but in no case is there any crop of fruit this year. *William Keen, The Gardens, Bowden Hall.*

Crops of Apples, Pears, and Plums in this district are much below the average. In this garden, however, Apple and Pear trees which did not bear fruit last year have fair crops. Plums are an entire failure, although the trees flowered abundantly. Cherries were fine, and all kinds of soft fruit have been good. *C. C. Bolton, Stanley Park Gardens, Stroud.*

Apples and Pears are total failures here. Caterpillars were abundant. There were very few Cherries, and only half a crop of Morellos. Apricots are a failure. We have a few Plums, and a crop of Damsons on some of the trees. The failure of the Apple, Plum, and Pear crops is general throughout this locality. *J. Bunting, Tortworth Gardens, Falfield.*

—The out-door crops of fruit are the worst

I have experienced for many years. Trees that were not laden with fruit last year are not fruiting this year. Owing to the sunless autumn the wood did not get properly matured, and the blossoms were weak. Pears failed to flower. Apples, Plums, Damsons, and Cherries looked promising, and set a good proportion of flowers, but a heavy thunderstorm on May 18, accompanied by hail, and several subsequent sharp frosts at night, destroyed the blossom. Standard stone fruit trees are bare, and only here and there are a few Apples to be found. There are a few Apricots, Peaches, Nectarines, and Plums on wall trees. Morello Cherry trees on a north wall yielded a fair crop. Strawberries and bush fruits bore good average crops. Caterpillars have been very troublesome, and in some instances cleared the trees of their leaves, though drastic measures were taken to destroy them. Our soil is chiefly clay with a subsoil of bluish clay. *A. Chapman, Westonbirt, Tetbury.*

—— Fruit crops in the county are generally disappointing. There was plenty of Plum blossom, but late frost did it serious injury. The blossom on Pears was very scanty. Apple trees in orchards which did not bear last year bloomed fairly well, but the flowers were soon gone, and the trees never looked like setting a crop. Aphis, and the Ermine and Lackey Moth caterpillars have been very injurious. The trees also suffered from drought. This is one of the worst fruit seasons known in this county, and from reports generally there seems to be but little fruit in the whole country. *G. H. Hollingworth, Shire Hall, Gloucester.*

HEREFORD.—The fruit crops this season are poor, the only exception being Gooseberries, which bore a full crop. Apples bloomed well, but severe attacks of Apple-blossom weevil destroyed the majority of the blossom. The varieties that are carrying fair crops of fruit are Bismarck, Rival, Blenheim Pippin, King of the Pippins, Lord Grosvenor, Lane's Prince Albert, Tyler's Kernel, Royal Jubilee, Dutch Mignonne, Emperor Alexander, Golden Spire, Frogmore Prolific, Peasgood's Nonesuch, Golden Noble, Warner's King, Stirling Castle, Charles Ross, Hormead Pearmain, Lord Derby, and Newton Wonder. Pears are quite a failure; there was no bloom on the trees. Of Plums, the only sort carrying a crop is Pershore. Strawberries were poor owing to the drought. The soil is light, on a sandstone formation, and crops need plenty of moisture in spring and early summer. *Thos. Spencer, Goodrich Court Gardens, Ross.*

(*To be continued.*)

THE NARRAS.

ACANTHOSICYOS HORRIDA.

FEW Europeans have seen the remarkable Cucurbitaceous plant known as the Narras, which grows wild in Damaraland. It forms thorny bushes about 4 feet to 5 feet in height, and produces Melon-like, edible fruits in great abundance. The almond-shaped seeds are also edible. The plant is said to bear two crops of fruit a year, which is fortunate, as no other fruit-bearing plant appears capable of existing in Damaraland.

Acanthosicyos horrida obtains its supply of water from a considerable depth, and its roots are of extraordinary length. M. Dupargnet, a French botanist, who lived in Damaraland, measured a root which was 325 feet in length, with many hollow, fibrous branches.

Attempts have been made at Kew and elsewhere to grow this plant in gardens, but always without success. Mr. Naudin stated in the *Gardeners' Chronicle*, of 1886, p. 727, that he was able to grow the Narras with no more success than has been obtained at Kew. He tells us how easily the seeds germinate, but that the plants invariably perished when they were 1 foot to 1½ foot in height.

Six plants were raised in June, 1916, at Kew. The seeds were put singly into thumb-pots filled with sandy soil, and placed in tropical heat, where they soon germinated. Two cotyledons are developed as in Cucurbits generally, and one small lanceolate acute leaf, which is, as a rule, the only true leaf produced. As soon as the seedlings started to form a shoot they were planted in a bed made of sea sand and rough pieces of sandstone, in a sunny house devoted to tropical succulent plants. Five plants became established. Some seeds were also sown in this bed, and these germinated well, so that altogether 32 seedlings occupied this miniature desert.

Where the Narras grows wild heavy dews fall at night, therefore the Kew seedlings were syringed freely. Plenty of air was admitted when weather permitted, and the plants grew well for a time. The bed was well watered on several occasions, care being taken that the water did not reach the neck of the plants.

Twenty-nine healthy, vigorous seedlings lived until Christmas, 1916, but during the first week

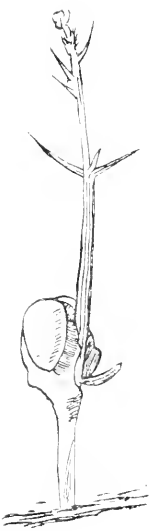

FIG. 46.—SEEDLING OF NARRAS (NAT. SIZE).

of January, 1917, several collapsed suddenly, and by the end of the month only seven remained alive. Two of these plants had stems over 2 feet long, and several branches. In the fourth week of February these two specimens died suddenly, and in January, 1918, all the others perished.

Death in nearly every case seems to have been due to excess of moisture. On the neck of the root a growth is formed which may be called a little appendix (see fig. 48). It contains a drop of liquid (sap), and this may have a bad influence at a time when transpiration is at its lowest, as it must be in short, dark, and moist winter days. We performed a surgical operation on two of the plants by cutting away the "appendix," but although they lived longer than most, they died before February, 1918.

It might be possible to grow and fruit Acanthosicyos horrida in Europe, and if not at Kew, perhaps in places where the winters are more sunny and less damp. Or it might be successfully grown on a commercial scale in the West Indies, at Antigua, for example, where the climatic conditions might suit it. *A. Bees, Royal Gardens, Kew.*

The Week's Work.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Cattleya, Laelia, and their Hybrids.—During the present month many plants of these genera that have recently passed out of flower will commence to push roots from the base of their pseudo-bulbs, particularly such as Cattleya Warscewiczii (gigas), C. Warneri, C. Hardyana and their many hybrids, and any that are in need of new rooting materials should be given attention. The same remark applies also to such Laelias as L. purpurata, L. tenebrosa; L.-C. elegans and their hybrids. I do not advocate unnecessary repotting of these plants at this season, but it is generally known that where numbers are grown they are not all ready to be dealt with at the same time. Repotting should be done when it is seen that new roots are developing from the new pseudo-bulbs or leading growth. These roots in every case should have sufficient space to grow inside the rim of the pots. Therefore, in giving the plant a larger receptacle, let it be of sufficient size only for two seasons' growth. When the plant has to be removed from the pot, the old, useless pseudo-bulbs, and especially those that have no leaves, should be cut away. Ample drainage must be provided. Pots which are to contain moderate sized plants should be filled to about half their depth with clean crocks, whilst for larger specimens a greater depth of drainage should be used. When repotting plants of the long bulbed section, which includes L.-C. elegans and L. purpurata, it is important that the plants be made firm by tying one or two of the pseudo-bulbs to neat, strong stakes. After being repotted the plants should be afforded only sufficient water at the roots to prevent shrivelling. Some plants of Cattleya Mendelii, C. Mossiæ, C. Schröderæ, and C. Trianæ have ceased to grow, and these should receive less water at the roots than hitherto. They should be exposed to all the light possible, and allowed plenty of ventilation; this treatment will assist the newly formed pseudo-bulbs to mature, and induce the plants to make many roots, and prevent premature growth. If any of these plants have grown too large for their pots, and are likely to suffer for want of rooting space, they may be placed into larger receptacles, but care must be taken not to disturb the roots more than is necessary. Merely break the pots and take away as much of it as possible, without interfering with the drainage. Then place the mass of soil and roots in a larger pot of suitable size. Many Cattleyas, Laelias and hybrids that flower in the autumn, such as C. Wendlandii, C. Portia, C. Mantinii, Laelio-Cattleya Tiresias and others that have finished their growth, should be kept rather drier at the root, affording only sufficient water to keep the compost moist. The flower-sheaths should be watched daily, and immediately the flower-spikes are observed pushing up at their base a slightly increased amount of water should be given, the supply to be again reduced when the flowers open. In many species and hybrids of Cattleyas and Laelias that have finished their growths it will probably be found during damp weather that the outer sheath that encircles the new pseudo-bulbs has become soft and sappy, and clings slightly to the pseudo-bulb, excluding the air. As this condition often causes the pseudo-bulb to rot, the sheath should be slit open from the top to the bottom. Keep the plant dry for a few days and reduce the amount of atmospheric moisture; this treatment will, in most cases, reduce the trouble.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Cucumbers. — The time has arrived when direct syringing of Cucumbers must be discontinued, but the necessary atmospheric moisture must be provided by other means, and at the same time the amount of bottom heat should be

increased. If young plants are still awaiting the removal of other plants, the latter should be cleared out as soon as possible, as plants that have been bearing for some months will not be worth keeping longer. A fair amount of fire-heat will be necessary to bring the fruits to perfection; these should not be allowed to grow so large as to exhaust the plant's energies. Lightly top-dress the roots as required with some of the compost recommended in the calendar for August 30, and use tepid water only at the roots.

Mushrooms.—Enough manure having been collected for the bed and well turned until thoroughly mixed and sweetened, it should be rammed into the beds as firmly as possible. But before proceeding to make the bed, let the house have a thorough cleansing and airing afterwards; also see to any repairs that are necessary. After the bed is made insert a thermometer, and when the heat declines to 85° insert the spawn just under the surface, about 9 inches apart, in pieces about 2 inches square. The surface should then be made firm and cased over with about 1½ inches of fine loam and again made firm with the back of a spade.

French Beans. — Seeds of French Beans which were sown in pots in the open to obtain plants for housing when frost threatens should be got under cover, otherwise their usefulness will be seriously impaired. Small batches are of little service, and not fewer than fifty 8 or 9 inch pots should be sown at intervals of three weeks. If pods are required soon the pots should be placed where the night temperature seldom falls below 60°, for Beans in pots require plenty of heat, light, and moisture. Not until the pots are well filled with roots will much water be required; liquid manure may be applied with advantage when the plants have arrived at a bearing stage. Thin the seedlings to about six in a pot, and support the growths with Birch twigs.

Cauliflowers. Where hand-lights and cold frames are available, Cauliflower seedlings should now be under cover. Unless the ground is very wet the plants should be well watered and kept close for a day or two until they are well established, when an abundance of air should be given whenever the weather permits. Dibble the plants out about 4 inches apart, and make them firm in the soil. Grow them near the roof-glass, and see that they are well supplied with water, but they must not be coddled. Slugs are very harmful to Cauliflowers, and a close watch must always be kept for these pests.

Cabbages. Fill all gaps in the rows of Cabbages and finish the transplanting of others in firm, clean ground that has not been recently dug. Remove all small, weak seedlings in the seed-beds to give space to those left, treading the soil about the plants. These Cabbages will be useful for planting next March and April, and will form a succession to those planted now. Keep the hoe at work constantly between these and all other crops to encourage growth while the open weather lasts.

Tomatos.—If not already done, the remainder of the out-door Tomato fruits should now be cut and placed under glass to ripen, as slight frosts and heavy rains would cause them to crack or rot.

FRUITS UNDER GLASS.

By W. J. GOSS, Gardener to Mrs. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

Strawberries in Pots. The continued wet weather is not suitable for the ripening of the crowns of Strawberries, although the plants grow apace, and apparently revel in moisture, which no doubt accounts for their exceptional cleanliness and freedom from red spider. Mildew has to be guarded against during a spell of such changeable weather; it is therefore advisable to dip the plants in or syringe them occasionally with soapy water in which a little sulphur has been dissolved. If the plants are given more space the quicker will the crowns mature. Keep the pots free from weeds, runners, and worms, although the last should not be troublesome if the pots are standing on a well soaked ash bottom. Weak stimulants at a gradually increasing strength should be given the plants when the pots are full of roots.

Muscat of Alexandria Grapes. — Where Muscat Grapes are ripe, or nearly so, gradually but well thin the laterals to allow more light and air to enter the bunches. Although a little fire-heat is necessary in dull, wet weather to keep the house dry, an excess would cause the berries to shrivel directly the leaves begin to fall; by freely ventilating the house in fine weather and gradually lowering the mean temperature, they should keep in good condition for a long time. The bunches should be examined frequently, and any decaying berries or foliage removed, otherwise the whole bunch may soon be affected. Should the borders need watering, let this be done early in the day, so that all surface moisture will have evaporated before night.

Young Vines. Afford liberal treatment to all young Vines, and any that are still in growth probably Black Hamburgh should be hastened forward by using a little warmth in the pipes. Those that have completed their growth should be divested of all laterals up to the primary point, unless they have lost all the main leaves, in which case it is advisable to allow a few leaves to remain on the shortened laterals to perfect buds for next year.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

Root Pruning Wall Plums. Certain varieties of Plums are more predisposed to make luxuriant growth than others. The most vigorous perhaps, are those of the Reine Claude section, as, for example, the Transparent Gage, Reading Gage, Althan's Gage. These are amongst the very best of all dessert Plums, and it is worth every effort to render the trees fruitful. As soon as the fruit is all gathered it will be advisable to do at least a little root pruning. Fresh soil need not be used. Proceed first by carefully tracing out the position of the roots, searching especially for any that are growing downwards into the subsoil. Plums these often root more so than the others, and it needs to push a fork pretty wide under the central part of the tree to prevent any roots taking the same course again. In the root pruning carefully, and if there be a deficiency of fibrous roots make a few incisions in the larger roots with a sharp knife. Do not use manure to trees that are too luxuriant in growth already. Reduce all sappy wood on the trees, and water the roots once to settle the soil, but first make the ground firm.

Choice Dessert Plums. As the planting season approaches, I would advance the claims of a few varieties of first-rate dessert Plums. I would recommend Kirke's, one of the finest for flavour, and a good cropper; Oullins' Golden Gage, an excellent early Plum, of fine quality; Ickworth Imperatrice, possibly the latest of all choice dessert varieties, and most useful for dessert purposes up to the end of October, and even into November, for use during the shooting season; Coe's Golden Drop, which is better known than many others, and a good companion to the preceding sort; Reine Claude de Bavay, a September Plum of a fine flavour, and one that keeps well; and Early Transparent Gage, one of the most prolific of this section. These half-dozen sorts are worthy of planting in any garden, and, moreover, are also suitable for planting against a wall with a glass coping.

Late Keeping Plums. Those who are fortunate enough to possess good crops of Coe's Golden Drop and Ickworth Imperatrice Plums will do well to gather the remainder of the fruits. Fold each perfect fruit in tissue paper and suspend it in a dry fruit room.

Figs on Outside Walls. — Reduce all superabundant growth on Fig trees against walls; first remove all sappy, green wood (unless any is needed for extension), and then see what more can be spared. If fruits are still on the trees expose them to all the sunshine possible. They may be gathered a few days before they are ripe and their ripening finished under glass. I am glad to find that those growers who persevere with the Fig in the open have been rewarded this season with a good crop. More growers should cultivate this fruit, especially those with the advantage of a warm, sunny wall. Depend upon Brown Turkey rather than any other variety. Prepare the border this autumn, but do not plant until the spring, say at the end of March.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Coleus thyrsoideus. — This plant requires plenty of stimulants during the final stages of growth in order to obtain fine spikes of flowers. Plenty of air must be admitted to the plants when the weather is warm and genial, and a little air should be admitted at the top of the house during the night. A minimum temperature of about 56° will be ample until the plants are in flower. It may then be reduced by 5°.

Violets. The work of planting Violets in frames should be no longer delayed, as it is a great advantage to get them well established in the new soil before the winter. Plant firmly and as near the roof-glass as practicable. When the roots have recovered from the check caused by disturbance let the plants have an abundance of air, removing the lights altogether when ever the weather is favourable.

Cineraria.—Shift the latest Cineraria plants into their flowering pots as soon as they are ready. Give them a good, substantial compost and pot firmly. The pots should be stood on a cool bottom and the plants kept in cool conditions throughout the autumn and winter, using fire-heat only to keep out frost. Fumigate the plants occasionally to keep them free from aphis.

Rhododendron indicum. It is no longer safe to leave Indian Azaleas out of doors. Place them in a light, airy structure, and let them have an abundance of air at all times till there is danger of severe frost. Before shifting them indoors lay the pots on their sides and thoroughly drench the shoots with an insecticide as a precaution against red spider.

THE APIARY.

By CELONUS.

Making Hives Watertight. In order that stocks may go through the winter safely, it is essential that the hives should be quite weather proof, for dampness is the prime cause of dysentery. The best method is to remove all chipped paint from the hive by scraping; rub down the surface with glass paper, and fill all cracks with putty or white lead. The roof should be painted, and while the paint is wet, tightly stretch over a piece of calico and tack it on round the edge of the hive with thin laths, then give several coats of paint. The rest of the hive should be painted, remembering it is not the amount that is applied at each coating, but the working of the paint into the wood at each application that matters. To paint thickly is to waste material. To those who wish to make their own paint the following hints will be helpful, and I may add it is best to make your own. The following will make sufficient to paint an ordinary 10-framed hive with one coat. Take one pound of white lead and mix thoroughly with equal quantities of linseed oil and turpentine, adding the liquid slowly as the white lead requires more to mix it to a workable consistency. For the first coat it may be made thinner than the succeeding ones. Since the weather is very unsettled now it would cause the paint to set quicker, and also make it harder, if a tablespoonful of gold size be well stirred into the paint. Those who do not desire white painted hives may produce stone colour by adding yellow ochre and burnt umber until the required tint is reached, and a slight quantity of sienna will result in a stone colour of a rich tint. To make lead or slate colour, stir in lamp-black. This colour is often desired, as it does not show dirt so readily as other tints, and may be used for roofs only if desired. Boiled oil may be used but it must be remembered that it blisters very readily. When the paint is well mixed strain through a piece of old stocking to produce paint of an even consistency and colour; further it will produce a better surface after straining, as all grit and other foreign matter will be removed.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 41, Wellington Street Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *and as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 54.0°.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, September 25, 10 a.m.: Bar 29.9, temp. 66°. Weather—Bright.

SALES FOR THE ENSUING WEEK.

TUESDAY and WEDNESDAY—
Rhododendrons, Hardy Heaths, &c., at the Sunningdale Nurseries at 12 o'clock each day.

THURSDAY—
Sale of Bulbs at 67-68, Cheapside, E.C., at 1 o'clock.

The Fuel Problem.

Since we made the announcement in the issue for July 6 that the Controller of Coal Mines hoped to be able to furnish an allowance of fuel for the heating of glasshouses in private establishments, the coal problem has become more acute, and fuel may or may not be forthcoming. As it is no longer safe to allow tender plants to remain unprotected, they should be housed for the winter at the earliest opportunity, and the measures we recommended in the former article on the subject—some of which we again refer to below—adopted.

The decision to include wood in the control is unfortunate, as otherwise many could no doubt have supplemented their coke or coal allowances by obtaining wood locally. The situation must be faced. Coal, says Marshal Foch, is the key to victory, and, as all the Allies must be supplied from this country, it is the duty of everyone to save coal, however inconvenient they may find it, either in the house, in the garden, or in the workshop.

The allowance for commercial establishments is about 20 per cent. less than the average consumption for the past three years. Market gardeners and nurserymen who employ artificial heat for forcing, will find it difficult to manage with three tons of coke or coal instead of four. They at any rate do not burn fuel extravagantly, whatever may be done in private establishments, and they will not, therefore, be able to reduce their fuel consumption by a fourth without considerable sacrifice of income. In other words, they will be heavily taxed by the new fuel order.

In private gardens there is less need for anxiety. Fire-heat for vines, Peaches, and other indoor fruits will not matter until the stress is ended; good crops of Grapes and Peaches have been grown in houses this year without the aid of artificial heat. Ordinary decorative plants will probably have to be either reduced in number or consigned to the rubbish heap. This, however, need not be done at once. Many plants will endure a low winter temperature with little loss of health. By keeping the soil and atmosphere fairly dry even tropical plants may be preserved in unheated glass structures. Careful management of the ventilators and outer doors will also be found of material aid in maintaining a safe temperature in cold weather. Every gleam of sunshine should be caught, and at night the roof-blinds should be let down. By lighting a fire in the evening for an hour or two and warming the pipes, an ordinary greenhouse may often be made frost-proof. Frames can be covered with bracken, old straw, hay, or any material that will help to keep out frost. Gardeners need not hold up their hands in despair and say all is lost because fuel is scarce. There are other means whereby tender plants may be preserved from injury by cold.

It is surprising how many plants are able to withstand a lower temperature than we have been accustomed to provide for them. They do not grow as well in a low temperature, but they will keep alive through the winter, and when summer warmth arrives they start, as a rule, into vigorous growth, after a spell of what may be called winter rest. Our advice is, therefore, do not remove or throw away greenhouse plants because artificial heat for them is no longer available, but let them remain, and by the adoption of some such treatment as is here suggested, endeavour to keep them alive.

The Orchid collections, of which there are many of great value in this country, must be preserved somehow. The plants may be wintered safely in temperatures lower than is customary. We know growers who have decided to reduce their Orchid house temperatures by as much as 10° when the weather is trying. This can be done with safety, provided the atmosphere is kept dry. In nature, most plants are subject to extremes of temperature, and fortunately they are so constituted that they are able to bear it.

Village Clubs Association.—Under the chairmanship of Sir R. HENRY REW, and with an influential general committee which includes the Right Hon. R. E PROTHERO, M.P., Sir A DANIEL HALL, the Rt. Hon. F. D. ACLAND, M.P., and Lord HENRY CAVENDISH-BENTINCK, the Village Clubs Association has been formed for the purpose of promoting the establishment of clubs in rural villages throughout England and Wales. The principles upon which an Associated Village Club must be founded are as follows: (1) It should be a centre of social activities and of all forms of physical and mental recreation; (2) it should be self-supporting and free from the elements of patronage; (3) all inhabitants of the village, without distinction of class or opinion, and, when practicable, of both sexes, should be eligible for membership; and (4) the entire control should be vested in a Committee elected by the members. The Association will assist in the formation of Village Clubs on these lines and take such action as may be necessary to form a Club in every suitable village. Full particulars as regards membership and the work of the Association may be obtained from the hon. secs., Mr. A. GODDARD, 12, Great George Street, Westminster, and Mr. GEORGE DALLAS, 32, Charing Cross Road, London.

Women Gardeners' Wages at Kew. — The women gardeners at Kew have followed the example of the women 'bus conductors and others by protesting against the difference in their wages and those of the men, including labourers. The present rates are, including war bonuses, for men 43s. and 44s., for women 38s. 6d. The women replace gardeners who have enlisted, and they are expected to perform the same duties. They are trained gardeners, and we believe their work is satisfactory. The few young men now employed at Kew as journeymen gardeners are paid at the higher rate. If the cost of living is considered the women have a good case, as they are generally charged more for board and lodging than men. We hope the women at Kew will be successful in their appeal for fair treatment. Boys of fourteen, fresh from school, are now paid 15s. per week at Kew. The working hours now are 6 a.m. to 5 p.m. in summer; and 8 a.m. to 4.30 p.m. in winter, with two Saturday afternoons in three free.

More Bees.—Interest in bee-keeping is stated to be reviving rapidly, due, no doubt, to the decreasing virulence of the Isle of Wight disease. Many bee-keepers have patriotically increased their colonies for distribution to those anxious to keep bees but who find a difficulty in obtaining stock. Owing to the unfavourable season in certain districts, these nuclei and late swarms will need attention if they are to survive the winter. Experiments made during the past three years suggests the possibility of the production at an early date of a strain of bee in this country practically immune against the Isle of Wight disease. The importance of the bee to the fruit-grower is widely recognised.

Horticultural Club.—The Committee has made arrangements to continue the joint tenancy of The Farmers' Club, 2, Whitehall Court, Westminster, and will inaugurate the winter session by a members' lunch at 1 p.m. on Tuesday, October 8, in the dining-room in the Club building. Representatives of the Committee will be present to meet the members and afford them opportunity of inspecting the Club's new quarters. Whitehall Court is situated at the back of the War Office, Whitehall Place, Westminster.

Gardeners and War Service.—In a circular letter the Local Government Board calls the attention of the tribunals to the importance, as a part of the general policy of food-production, of maintaining the kitchen gardens of private households. "Exemption should," says the circular, "generally not be refused to an experienced kitchen gardener whose exemption is found to be essential for the production of large quantities of necessary food supplies. Before, however, granting exemption in any case the tribunal should satisfy themselves (a) that the principal and usual occupation of the man is, and has been for a considerable time, that of a kitchen gardener; (b) that most of his time is spent in raising necessary food supplies, and that the quantity raised is sufficient to warrant exemption; and (c) that, unless he is of low medical grade, a suitable substitute could not be obtained for him or other arrangements could not be made, with effort, for the essential part of his work. If a man is engaged partly on kitchen

gardening and partly on other work which is not of national importance, exemption should, when reasonable, be granted on condition that, in addition to his ordinary work as a kitchen gardener, he devotes a specified time to other essential work, particularly, where opportunity offers, to other kitchen gardening or agriculture. The above recommendations do not apply to men who cultivate gardens or allotments in their spare time." Agricultural vouchers have in some cases been mistakenly given to men engaged in kitchen gardening. Any application for the exemption of a man from whom an agricultural voucher so given has been withdrawn is to be entertained, although made out of time. National Service representatives have been instructed that any necessary consent shall be given in such cases.

War Items.—As a result of a fowl exhibition the Cox Green and District Horticultural Society has presented an Ambulance Motor Car, together with a sum of about £70, to Maidenhead Red Cross Hospital. The presentation was made by the President of the Society, F. I. FORD, Esq., who congratulated Mr. T. BEDFORD and his Committee on the success of the exhibition.

—— We deeply regret to learn that Sergt.-Major SEARLE, son of Mr. ALFRED SEARLE, Larkenshaw Gardens, Chobham, Surrey, has been killed in action after 3½ years' active service in France.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Blanching Celery. Has anyone tried the paper as a substitute for the paper collars that used to be sold for blanching Celery? Ordinary brown paper, especially of the quality sold nowadays, soon rots and becomes worse than useless for the purpose, so it seems to me that the washable wall papers should, when cut into suitable sizes, be ideal for blanching Celery. Almost all house decorators have odd rolls on hand left over from decorating, and these remnants they used to be glad to sell cheaply; though both are cheap nowadays.—*H. C. Bartlett.*

A Heavy Potato Crop (see p. 121). Last season I planted one peck of sets of Sutton's Edinburgh Castle Potato and the resulting crop was 5 cwt. of good tubers. This year the Hertford Horticultural Society organised a Potato competition, and for it I selected 30 sets of Edinburgh Castle, and lifted a crop of 2 cwt. of tubers therefrom, one root weighing 15 lbs. All the tubers were sound and of good average size, free from disease; they cook splendidly. The ground was trenched early in the spring, and well manured, and a dressing of wood ash was applied before planting, but no artificial manure was used.—*W. Stephenson, Bircham Newton Gardens, Hertford.*

Inequality of Yield, per Set Planted, of Potatos. Inequality of yield exists, when conditions, such as soil, situation, and methods of cultivation, are as far as possible exactly the same, and it would appear to be caused by some quality or attribute in the set or tuber itself. When the sets are placed in boxes for sprouting the sprouting is uneven, as to time and quality of the sprouts, indicating differences in the sets themselves. Do any advanced growers plant only the set with the strongest sprouts and discard those that are weaker? The custom here is to plant all the sets, except the few that might happen to be blind.—*H. Bostock, The Oaklands, Rowley Avenue, Stafford.*

Potato Spraying.—The booming of Burgundy mixture by the Food Production Department has been conducted in a manner which is hardly fair to the manufacturers of other fungicides. No doubt the manufacturer's ultimate aim is profit, but, after all, he does his best for the grower, if only because success lies in that direction; and he has sunk his capital in, and gives his time to, his business. Is it right that a public department should use the money of the taxpayer to disseminate statements calculated to injure this business? The chemical speculations and rhapsodies of mycologists and *cidevant* horticultural lecturers call for no comment, but statements of supposed facts are sometimes made which, to say the least of it, are unwarranted. One of these has been brought to my notice more than once; it is to the effect that the basic sulphate of copper, when reduced to the form of a paste—now known as Bordorite—loses its adhesive properties, and is much inferior in this respect to freshly made Burgundy or Bordeaux mixtures (see Dr. A. S. Horne, in *The Fruit Grower*, April 4, 1918). Such a statement was quite unjustifiable, because up to that time no determinations had been made, or, at any rate, published, of the relative adhesive powers of the substances in question. As there were reasons for supposing that the facts might really be the reverse of those stated, an investigation of the matter was undertaken at Wolverne. Nine plots of Potatos, of one twelfth of an acre each, were sprayed on the same day with Burgundy mixture, Bordeaux mixture, and Bordorite, each of three different strengths, but of strengths such that in each case the three substances contained the same amount of copper; this amount was equivalent to 20 lbs. of crystallised copper sulphate to 100 gallons with the strongest washes, 10 lbs. with the intermediate ones, and 3½ lbs. with the weakest ones. The plots were first sampled one week after the spraying, taking, for the purpose, one leaf from every plant in each plot (except from the plants in the outside rows); the rainfall during the week had been 0.17 inch. A second sampling was made one month after the spraying, the rainfall having then amounted to 0.76 inch. The relative amounts of copper found on the leaves, as compared with that in the case of Burgundy mixture, expressed as 100, were:—

	After 1 week.			After 1 month.		
	20 lbs.	10 lbs.	3½ lbs.	20 lbs.	10 lbs.	3½ lbs.
Burgundy	100	100	100	100	100	100
Bordeaux	108	103	122	91	101	154
Bordorite	121	139	204	150	111	125

Thus, in every single case the adhesiveness of Bordorite is greater, generally much greater, than that of Burgundy mixture, and in five cases out of six, greater than that of Bordeaux mixture; whilst a comparison of Burgundy with Bordeaux mixture gives a superiority to the latter in every case but one, though the superiority is generally not a large one. The behaviour of these substances is in accordance with conclusions based on a consideration of their nature. In every case the ultimate deposit on the leaves is in the form of the carbonate or, rather, a carbonate of copper; with Burgundy mixture it is deposited on them initially as carbonate: with the other two, as basic sulphate, which becomes converted into carbonate; and such conversion *in situ* implies a much finer and more adherent deposit than when the carbonate is applied to start with. The superiority of Bordeaux over Burgundy mixture in this respect is, however, reduced by the presence of the gross particles of excess of lime in it (soon becoming converted into chalk), which are easily knocked off, and, of course, carry with them a considerable amount of the copper, reducing its adhesiveness nearly to the level of that of Burgundy mixture.—*Spencer Pickering.*

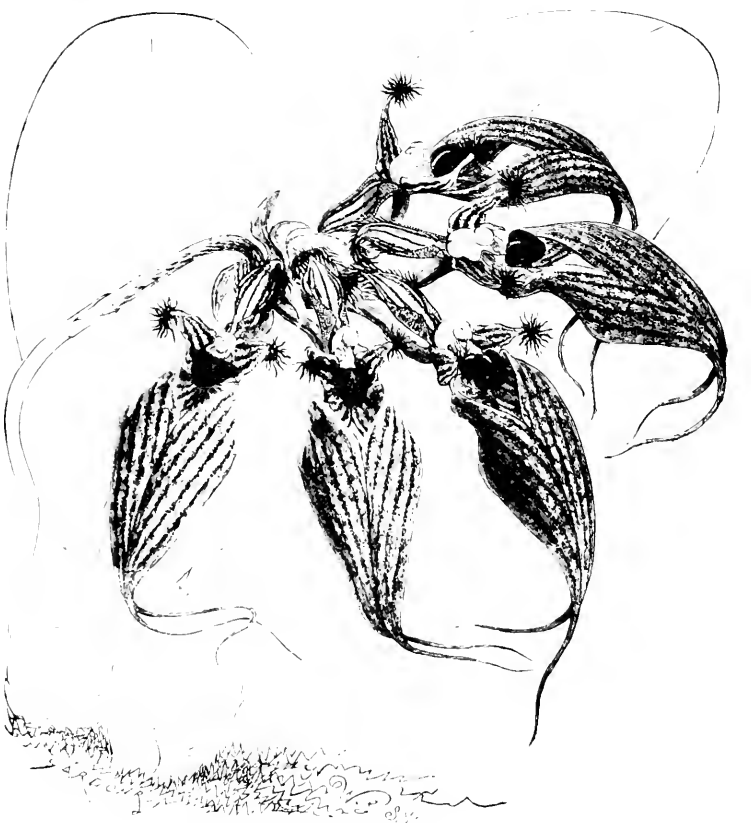

FIG. 91.—CHLOROPHYTUM ORNATISSIMUM.
(See p. 135.)

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

SEPTEMBER 10.—*Present* Mr. E. A. Bowles, V.M.H. (in the chair), Messrs. E. J. Allard, W. Hales, J. Fraser, and J. W. Odell.

Potato Wart Disease (*Sorosporium scabies*).—Mr. F. J. Froghrook attended and exhibited Potatos affected with wart disease. It was pointed out by the Committee that the disease was notifiable, and every effort should be made to destroy the affected tubers on the Leyton Allotments, where the outbreak had occurred.

Fasciated Maize. — Mr. A. T. Johnson exhibited a spike of Maize showing fasciation with male and female parts reversed. A similar exhibit also came from Mr. Fraser.

Larix Kaempferi.—A fruiting branch of this Larch, taken from the original imported plant, was sent by Mr. G. Paul. The specimen was well covered with small, green, Artichoke-like cones.

Lycium chinensis.—Mr. Odell showed a branch of this Chinese Box Thorn bearing numbers of coral fruits. It was grown in the London area, and was considered by the Committee to be the variety megistocarpum.

SEPTEMBER 24.—The meeting held in the London Scottish Drill Hall on this date was unusually well attended, and there was a very pleasing briskness about the whole of the proceedings. The exhibition was given over very largely to vegetables staged in competition for prizes offered in 48 classes, with several splendid non-competitive displays, including one from EUSTACE PALMER, Esq., Sherfield-on-Loddon, Basingstoke, to whom a Gold Medal was deservedly awarded.

Orchids were very gay, but comparatively few were shown. Trees and shrubs were fairly prominent. Dahlias, in gorgeous colouring, were plentiful, and there were a few hardy border flowers.

The Floral Committee granted one Award of Merit and seven Medals; the Fruit and Vegetable Committee recommended one Award of Merit and three Medals; the Orchid Committee granted two Awards of Merit and two Medals. The joint R.H.S. and National Dahlia Society's Committee selected fourteen new Dahlias for awards from a bewildering number of novelties.

Floral Committee.

Present: Messrs. H. B. May (in the chair), G. Reuthe, John Heal, W. Howe, G. Harrow, A. Turner, J. W. Moorman, C. Dixon, W. J. Jones, Chas. E. Pearson, W. P. Thomson, W. J. Bean, John Green, Sydney Morris, E. A. Bowles, Jas. Hudson, C. R. Fielder, J. F. McLeod, R. C. Notcutt, and John Dickson.

AWARD OF MERIT.

Aster Robinson, V.C.—The group of useful double Michaelmas Daisies has been enlarged by this new-comer, which is erect, free-flowering, and has shapely blooms of a clear medium blue colour. Shown by Mr W. WELLS, junr.

GROUPS.

Two groups of Roses added fragrance and beauty to the general display. The Rev. J. H. PEMBERTON staged varieties of his own raising, including a new pale apricot-yellow seedling named Miriam (Silver Banksian Medal). Mr. ELISHA J. HICKS had a charming group of Roses, wherein Princess Mary and Chas. E. Shea were prominent varieties (Silver-gilt Banksian Medal). In Mr. G. REUTHE'S display of hardy and semi-hardy plants we noticed Kirengeshoma palmata, with a yellow, pendulous Abutilon-like flower, and a cluster of flowers of Eucalyptus ficifolia (Bronze Flora Medal.) Mr. W. WELLS, junr., contributed a fine lot of Delphinium spikes (Silver Banksian Medal); Messrs. J. CHEAL AND SONS staged fruiting and bright-foliaged trees and shrubs and "Star" Dahlias (Silver Flora Medal); Mr. L. R. RUSSELL put up a first-rate group of standard and bush specimens of many varieties of tree Ivies (Silver Flora Medal); Messrs. H. B. MAY AND SONS grouped Salvias and Veronicas with various Ferns (Silver Flora Medal); and Messrs. PIPER AND SON staged various shrubs, notably Corokia variabilis and Berberis Gagnepainii, with hardy Cyclamens (Silver Banksian Medal).

Polygonum campanulatum, exhibited by C. SCRASE-DICKINS, Esq., Coolhurst, Horsham, is a useful hardy plant, as it flowers in autumn as well as in summer.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Messrs. Jas. O'Brien (hon. secretary), Frederick J. Hanbury, R. A. Rolfe, J. Wilson Potter, Arthur Dye, W. J. Kaye, C. J. Lucas, Walter Cobb, S. W. Flory, W. H. Hatcher, J. Charlesworth, Fred Sander, H. G. Alexander, E. R. Ashton, Pantia Ralli, J. Cypher, and J. E. Shill.

The chairman referred with sorrow to the death of Mr. Eric H. L. Davidson, a member of the Orchid Committee, who was killed in action in France on August 27 last.

AWARDS.

AWARDS OF MERIT.

Laelio-cattleya Ivanhoe (*C. Dowiana aurea* × *L.-C. eximia*), shown by Mr. J. E. SHILL, The Dell Gardens, Englefield Green.—A large and handsome flower with bright rose-coloured sepals and petals. The broad lip is crimped at the margin and coloured deep ruby-crimson, the colour extending to the side lobes and merging into light violet. The disc of the lip is tinged with yellow, into which gold lines run from the base.

Cattleya King Victor (*Rhoda* × *Octave Doin*), from Messrs. FLORY AND BLACK, Slough.—A fine hybid, shown with its first flower, and which should develop still greater beauty, as C. Dowiana occurs thrice and C. Mendelii, C. Warscewiczii and C. bicolor each once in the parentage. The sepals and petals are rosy-mauve, freckled on the outer halves, with cream colour; the finely-expanded, crimped lip is claret-crimson with well-defined gold lines from the base.

GROUPS.

Messrs. STUART LOW AND CO., Jarvisbrook, Sussex, were awarded a Silver-gilt Flora Medal for an excellent group composed principally of hybrids raised by the firm, and including a selection of Cattleya Hardyana varying from the white-petalled and blush-white forms to good representatives of the dark-coloured type. Among Cattleyas good forms of C. Warscewiczii and C. Lodd.izesii (with twelve flowers on a spike), and the yellow C. Baron Delbeke (Pittiana × Dowiana aurea) were noted.

Messrs. CHARLESWORTH AND CO., Haywards Heath, were awarded a Silver Flora Medal for a group of hybrid Cattleyas, Laelio-Cattleyas and Odontoglossums with a selection of rare species, among which was a fine specimen of the rare Bulbophyllum ornatissimum with four spikes (see fig. 49—the first of the genus to receive a First-class Certificate when shown by the late Sir Trevor Lawrence on October 24, 1893. Its graceful umbels of cream and claret-coloured flowers are very attractive. Specially noteworthy in the group were Laelio-Cattleya Carmencita var. Gloriosa (L.-C. luminosa × C. Dowiana aurea), with bright yellow sepals and petals and intensely dark maroon-crimson lip, and the new Brasso-Laelio-Cattleya Joiceyi (B. L.-C. Cooksonii × C. Rhoda), with clear yellow flowers having a well-formed fringed lip of rosy-crimson colour.

Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells, showed three forms of their pretty Laelio-Cattleya Golden Wren (C. iridescens × L.-C. Thyone), varying from the narrow-lipped bicolor type to the more ample C. Eldorado form. All were of shades of yellow with purplish front to the lip; also the white Cattleya Harrisoniana alba Stanley's variety, C. Venus, and C. Iris Orchidhurst variety.

W. J. KAYE, Esq., Caracas, Ditton Hill, Surbiton, showed Laelio-Cattleya Bola (L.-C. Callistoglossa × C. labiata), a fine flower with the rose sepals and petals of C. labiata and the trumpet-shaped lip of the other parent; the front of the lip is very dark ruby-claret.

Fruit and Vegetable Committee.

Present: Messrs. A. H. Pearson (in the chair), Joseph Cheal, John Harrison, W. Poupart, W. H. Divers, H. Markham, George P. Berry, E. W. Roach, W. Pope, J. W. Bates, A. Bullock, P. W. Tucker, F. R. Ridley, and Rev. W. Wilks.

The Committee had a very busy time in connection with the extensive displays of vegetables.

AWARD OF MERIT.

Apple James Lawson.—An interesting, useful, and attractive Apple, raised by crossing Cellini Pippin with Gravenstein. It is a good cropper. The fruits are of medium size, approximating to the Cellini shape, and coloured with crimson shading and stripes on a green ground. The flavour is good, and the flesh is firm and juicy. The fruiting trees at Swanley have been inspected by a sub-committee, which reported favourably. Shown by Messrs. H. CASSELL AND SONS, Swanley.

GROUPS.

A magnificent exhibit, filling a 40-feet length of tabling, was made by EUSTACE PALMER, Esq., (gr. Mr. W. H. Wallis), Sherfield-on-Loddon, Basingstoke. Practically all seasonable vegetables in the highest state of perfection and arranged with great skill were on view. Special mention, however, must be made of the Scorzonera, Celery, Parsnips, Blood Red Onions, Broad Beans, and Congo Potatos. (Gold Medal.)

Messrs. WEBB AND SONS staged a collection which included very fine Altrincham Celery, Blood Red Onions, Celeriac, The Dean and Edgecote Purple Potatos, and Cauliflowers. (Silver Knightian Medal.)

Messrs. SUTTON AND SONS had an exhibit of vegetables, raised from seeds sown on July 15 of this year, much on the lines of the interesting collection at the previous meeting, but in a more advanced condition. The Black Spanish Radish, Improved Queen Onions, Peas, and Kohl Rabi had made most gratifying progress. (Silver Knightian Medal).

Messrs. H. CHAPMAN, LTD., displayed uncommon Marrows, such as Delicacy, Rotherside Mammoth, and Melon Marrow.

Splendid bulbs of their Premier Onion were shown by Messrs. DICKSON AND ROBINSON, and Messrs. W. ARTINDALE AND SONS showed the yields of various Potatos, such as Edzell Blue, Majestic, British Queen, and King Edward. Mostly the tubers were immense (one was said to weigh 1 lb. 15 oz.), but far too large, and often coarse for general use.

COMPETITIVE VEGETABLE CLASSES

Both in point of entries and general excellence of exhibits these classes were fully equal to former years. Potatos, Onions, Cauliflowers, Runner Beans and Tomatos, Leeks were perhaps the best of the many kinds of vegetables shown.

TWELVE KINDS DISTINCT.

There were only two exhibitors in this premier class, which requires vegetables selected from those named in a published list. The 1st prize, which includes the "Sutton" Challenge Cup, was won by W. H. MYERS, Esq. (gr. Mr. G. Ellwood), Swanmore, Bishop's Waltham, whose excellent collection included superb examples of Tender and True Parsnip, Gladstone Pea, Prizetaker Leek, New Red Intermediate Carrots, and Ideal Potatos; 2nd, the Duke of WELLINGTON (gr. Mr. E. Matthews), Mortimer, Berks, who had magnificent Red Intermediate Carrot, Black Beet, Autumn Giant Cauliflower, and Cucumbers.

NINE KINDS DISTINCT.

This class is specially arranged to illustrate vegetables of the size and quality most useful for the table, and from this point of view, as well as attractive arrangement, the 1st prize, which includes the Gordon-Lennox Challenge Cup, was well won by Mrs. JENNER (gr. Mr. H. Wheeler), Wenvoe Castle, Cardiff. Every item was the acme of freshness, moderate in size, and of perfect shape; special mention may be made of the Snowdon Cauliflowers, Gladstone Peas, Standard Pink Celery, and Premier Onions; 2nd, EUSTACE PALMER, Esq. (gr. Mr. H. Wallis), Sherfield-on-Loddon, Basingstoke, who showed excellent solid white Celery and Champion Horn Carrots.

SIX KINDS DISTINCT.

In this smaller class the same high quality obtained, and Mr. T. JONES, Bryn Penylan,

Ruabon, who won the 1st Prize, showed excellent Ailsa Craig Onions, Comet Tomatos, and St. Valery Carrots; 2nd, Mr. J. S. KELLY, The Gardens, Clairemont, Esher, whose outstanding dishes were of Gladstone Pea, Onions and Potatos.

POTATOS, TWELVE VARIETIES.

In this and the next class the exhibitors favoured the more shapely kidney Potatos to the rounds and ovals. G. THORN, Esq., was placed 1st with nearly perfect dishes of such sorts as Royal Kidney, Up-to-Date, Moneymaker, Sharpe's Express, and Majestic; 2nd, A. THOMAS, Esq., Kingsnorth, Ashford, of whose collection The Gardener, Up-to-Date and Windsor Castle were particularly good; 3rd, C. A. CAIN, Esq. (gr. Mr. H. Pateman), The Node, Welwyn.

The best collection of six varieties, staged by Mr. F. G. HOAD, Willesborough, included Factor, Sharpe's Express, and Arran Chief; 2nd, A. G. MCMEEKIN, Esq. (gr. Mr. J. COX), Boulter's Lock, Maidenhead; 3rd, Rev. J. B. LEIGH (gr. Mr. G. Johns), Yalding, Kent.

ONIONS.

The required six dishes were to be selected from half-a-dozen named types. Mr. JONES was placed 1st with magnificent bulbs of Ailsa Craig (both oval and round), Premier, Crimson Globe, Silver Queen, and others; 2nd, W. H. MYERS, Esq., who also had fine bulbs of Ailsa Craig and Brown Globe.

SALADS, SIX KINDS.

Showing Batavian Endive, beautifully blanched, Ideal Lettuce and Perfection Tomatos in his collection, the Duke of WELLINGTON was placed 1st; 2nd, W. H. MYERS, Esq.; 3rd, E. PALMER, Esq.

SINGLE DISH CLASSES.

The visitors could not help remarking that the prizewinners of collections were also prominent exhibitors of single dishes of vegetables and of equally high quality. Scarlet Runner Beans measuring 16 inches long, were almost perfectly straight, and quite tender, and Cauliflowers, in this difficult season, were excellent. To many accustomed to the large heads at local shows, the small size of the Cabbages called for comment, though it was realised that these were of superior quality.

The Duke of WELLINGTON won 1st prizes for (a) French Climbing Beans, (b) Cabbages, (c) Marrows, (d) Parsnips, (e) Peas, and (f) Tomatos, as well as four 2nd prizes. Mrs. JENNER excelled for (a) Scarlet Runner and French Beans, (b) Long Beet, (c) Onions, (d) Carrots, long and short, and (e) Red Tomatos. Mr. T. JONES won 1st prizes for (a) Celery, White and Red, (b) Leeks, (c) Yellow Turnips, (d) Curled Kale, and (e) Cauliflower. E. PALMER, Esq., was placed 1st for Savoy Cabbages, and won the 2nd prizes in several other classes. The Rt. Hon. T. E. HARVEY (gr. Mr. T. Avery), Gaddesden Place, Hemel Hempstead, had the best White Turnips and White Potatos. The Hon. Mrs. GREVILLE showed the best Globe Beet, E. THORN, Esq., the premier coloured Potatos, and Mr. J. KELLY won the 1st prize in the class for any other vegetable with Red Cabbages.

NEW DAHLIAS.

The joint committee, composed of members of the Floral Committees of the Royal Horticultural Society and the National Dahlia Society, was as follows:—

Present: Messrs. H. B. May (in the chair), Joseph Chas. D. B. Crane, John Green, H. J. Jones, J. W. Jarratt, Arthur Turner, and Chas. H. Curtis.

Mr. Jarratt was granted permission to change the name of his new Collerette Dahlia from Péronne (see p. H2) to Cambrai. The following Dahlias received the R.H.S. Award of Merit and the N.D.S. First-class Certificate.

Hero.—This medium-sized, very double decorative variety is an intense dark maroon colour. It is of good shape, but the outer segments reflex somewhat, as in the older show class. Stems long, stiff, and dark.

Sunray.—A very large and beautiful decorative Dahlia, and a splendid garden variety. The colour is soft yellow overlaid with a flush of salmon pink. The segments are broad, and some of the outer ones are twisted.

Lynx.—A giant Collerette Dahlia of excellent form. The broad, rounded segments make up a flower that is sure to attract competitors. The colour is bright orange or soft scarlet, and the large collar is bright yellow. The stems are sufficiently stiff to carry the blooms erect. Those three varieties were shown by Mr. J. C. WEST.

Scout Star.—A charming addition to the "Star" group, with neat, deep pink, yellow centred flowers of capital substance, borne erect on stout stems. Shown by Messrs. J. CHEAL AND SONS.

Labour.—A particularly pleasing decorative Dahlia that should prove very useful in the garden and also for large indoor decorations. The blooms are of good shape, and carried on stiff stems. The colour is primrose yellow with a deeper yellow shading over the centre.

Sydney Jones.—A large Cactus variety, of elegant form, the segments being long and slender. The colour is lilac pink, with a rich golden glow over the centre arising from the yellow bases of the segments. These two varieties were shown by Messrs. J. STEEDWICK AND SON.

White Top.—Although not of exhibition form this long-stemmed, free flowering Collerette variety is a fine garden plant, as the blooms are splendidly poised large, flattish, and with white tips to their broad, rich, deep crimson-scarlet segments.

Daddon.—One of the showiest of Paeony flowered Dahlias, and one in which the large, orange-coloured flowers are carried erect on long, stiff stems.

Dragoon.—A very double decorative variety, exceptionally free flowering, and of dwarf habit. The colour is deep, rich scarlet. The flowers are of large size, and the stems carry them stiffly erect.

Medusa.—A very free flowering and handsome decorative variety of first rate and regular form, the segments overlapping each other and increasing in length from the centre outwards. The colour is primrose yellow with a faint but pleasing pink suffusion at the tips.

Tulip.—A showy Collerette variety with flowers of good shape and substance. The colour is a most effective combination of deepest scarlet and yellow, the latter colour being most evident in the short collar and the margins of the segments. Stems long and stiff. The foregoing five varieties were shown by Messrs. BARPELT AND CO.

Scout.—This big semi-double Paeony flowered Dahlia is of rather rough form, but the showy, bronzy-red colouring is quite attractive. The flowers have two rows of very broad segments round a small golden centre. Stems rather weak.

Star of Devon.—A giant Collerette variety, with broad, bluntly pointed segments that reflex slightly. The form is not of exhibition standard, but the colour, richest old rose, with scarlet shading, and a red and white collar, is very distinct. Stems stiff and slender.

Saxon.—This very neat Collerette Dahlia is most attractive in form and colour. The latter is soft orange scarlet over yellow, the yellow showing at the tips of the segments. The collar has broad divisions, and is clear yellow. The three foregoing varieties were shown by Mr. J. V. JARRATT.

NATIONAL CHRYSANTHEMUM.

SEPTEMBER 23.—The first meeting of the Floral Committee was held at Essex Hall, Essex Street, Strand, during the afternoon of the above date. Mr. D. B. Crane was elected chairman for the ensuing year.

Four novelties were on view, and Commendations were granted to the following:—

Miss G. E. Thorpe.—An elegant, white, medium-sized Japanese variety, very free, and good alike when disbudded or grown in sprays. It is early-flowering, and may be described as a glorified Roi des Blancs, from which it has descended. Shown and raised by Mr. ALEX. W. THORPE, Lichfield.

Red Anemone.—A distinct and neat centred early variety, very free-flowering and attractive; a useful border plant. The colour is bright red, with a golden-bronze centre; the latter is not obtrusive, but quite in proportion with the spread of the ray-florets. The flowers are just under 3 inches across. Shown by Mr. A. W. THORPE.

The Executive Committee met in the evening at 35, Wellington Street, Covent Garden, under the chairmanship of Mr. Thos. Bevan. Judges were appointed for the Finchley and Westminster exhibitions, and five new members were elected. A balance of £52 in hand was reported, and the Reserve Fund still intact. The proceedings were very brief.

CROPS AND STOCK ON THE HOME FARM.

CONDITION OF THE CROPS.

THE crop reporters of the Board of Agriculture, in reporting on agricultural conditions in England and Wales on September 1, state that the fine weather which prevailed through most of August was everywhere very favourable to harvest operations, and a great deal of corn has been got in under excellent conditions. The rain which occurred, mostly towards the end of the month, caused little delay or damage. In the north, the harvest is naturally not so far advanced, and there are many reports of the corn having been laid. Wheat has proved to be the best crop of the year throughout the country; the ears are reported to be well filled, and straw of a good length. With an area under this cereal of 2,550,000 acres and a yield now estimated at 10 per cent. above average, a production in England and Wales may be anticipated of 10,500,000 quarters, or fully 3,500,000 quarters more than last year. Barley is about an average in the north, but rather below in most other districts; the area this year is about 1,500,000 acres, and the total production should be nearly 6,000,000 quarters. Oats, like Barley, are more favourably reported on than a month ago, and the yield now appears to be but little below the normal. The acreage has been largely increased, and it is hoped that the 2,779,000 acres returned under this crop in England and Wales will yield 15,500,000 quarters, or 2,000,000 quarters more than last year. Peas and Beans are also satisfactory, and nearly average crops, though the latter, owing to aphis, are not quite so good as a month ago.

Potatos are still most satisfactory, and remarkably free from disease upon the whole. The area of 634,000 acres should yield some 4,160,000 tons of Potatos, or 750,000 tons more than last year.

Turnips and Swedes, though some improvement is generally noted from most parts of the country, have not recovered from the dry weather of the early summer; and fields are often very patchy. Prospects indicate accordingly a poor yield everywhere. Mangolds, although also considered to have made a little improvement, cannot be marked any higher than a month ago.

Summarising the returns, and expressing an average crop by 100, the appearance of the crops on September 1 indicated probable yields which may be expressed by the following percentages: Wheat, 106; Barley, 99; Oats, 99; Beans, 99; Peas, 99; Potatos, 105; Turnips and Swedes, 89; Mangold, 95; Hops, 71.

WHEAT FOR AUTUMN SOWING.

As the season for sowing Wheat will soon be here a few words about different varieties may be instructive to those who, owing to the ploughing up of grass land, have not grown this cereal before, or to those who have tried one variety but with little success. No doubt all the one hundred or more varieties of Wheat known possess some point of excellence, either in grain, straw, or adaptability for certain soils.

Such local conditions as soil and market requirements have to be considered when selecting Wheat for sowing. I am a staunch believer in growing one variety only, principally because I grow the bulk of my Wheat for seed purposes, and if there are several sorts on the farm there is a risk of mixing them. It is a risky business to finish a rick either at the top or the bottom with a second variety, as when threshing takes place much difficulty will be experienced in keeping the varieties separate. Where Wheat is grown for the mill only it does not so much

matter whether two or more red sorts are mixed. At one time some farmers were wont to grow both red and white Wheat in the same field, but that custom has almost died out. There is an advantage in this method, because all varieties do not ripen at the same time, and consequently cannot all be in the same condition for harvesting or milling. Those who grow purely for milling purposes would be wise to select a "strong" Wheat, which contains much gluten, and produces the largest quantity of flour. In these respects a good red Wheat is better than a white variety. Some varieties of Wheat produce more straw than others under ordinary cultivation, but that, however, is not so important as the yield of grain. The ordinary farm cultivator as a rule requires one good Wheat, and to such I strongly recommend Webb's Red Standard, which yields heavy crops of good milling grain and plenty of superior straw. In this variety I find few "pinched" corns, such as are all too common this season in many varieties. In some districts Square Head Masters is a popular Wheat, but I fail to see the distinction between this and Red Standard, therefore it matters little which is grown. Little Joss was raised by Professor Biffen from Square Head Masters and Indian Ghurka. This Wheat is a heavy cropper, especially on gravelly and sandy soils. Yeoman is the latest of Professor Biffen's varieties. It is said to be a heavy cropper on all soils.

Among white Wheats, Victor and Benefactor have a good reputation for cropping.

Sometimes it is convenient to sow Wheat in March or April where additional acreage is desirable. I had very good results this season on newly broken up grass land from Red Nursery, but it is possible that Burgoyne Fife is superior, giving a heavier yield of "strong" corn.

Rivett's and Percival's Blue Cone are bearded varieties, and desirable where sparrows are troublesome. The latter is said to be the best of all bearded Wheats.

It is generally known now that all cereals sold for seed purposes must be tested for germination and purity, therefore I advise all growers who think of selling their Wheat for seed purposes to remember that ten days must elapse before the necessary certificate can be obtained.

The quantity of seed to sow per acre varies with locality and circumstances. No doubt many of us sow the seed too thickly. Living as I do where rooks, starlings, and larks abound, I allow for the crop to be thinned by these birds, and accordingly sow 2½ to 3 bushels per acre in October, increasing this to 4 bushels per acre from the middle of November onwards. The more vigorous-growing Wheats naturally require more space to enable them to tiller freely in spring. The condition of the soil has a bearing on this point. When the land is in good heart, well prepared by the aid of sheep, farmyard manure, or a plentiful supply of artificial stimulants of a suitable nature according to the class of soil, then some consideration should be given to the quantity of seed sown. Dressing the Wheat before sowing to prevent an attack of "smut" (which is very detrimental to the yield as well as to the quality of the grain for milling), is an important detail. The two fungi which attack the Wheat plant are known popularly as "stinking" and "loose" smut. To prevent attacks the seed corn should be dressed with a solution of sulphate of copper, at the rate of 1 lb. of the sulphate dissolved in one gallon of water for each sack: 4 bushels of seed. Dress the seed by spreading it 6 inches thick on a hard floor, sprinkling it with the solution, and turning over the heap at least three times to thoroughly wet each grain; then throw the bulk into a heap and allow it to lie until the next day, when it will be nearly dry and fit for sowing. *E. Molyneux, Bishop's Waltham.*

TRADE NOTES.

MR. ERIC H. L. DAVISON.

We regret to announce that Mr. E. H. L. Davison, chief partner in the firm of E. H. Davison and Co., Orchid Nurseries, Twyford, Berkshire, was killed in action on August 27 last. He was a very popular personality among Orchid growers, and was the donor of the Davison Cup, which was annually awarded at the Royal Horticultural Society's summer shows. At the beginning of the war he joined the Artists Rifles.

MR. T. LEWIS.

Mr. T. Lewis, Ashburton Villa, Hanwell, terminates his connection with Messrs. John Waterer, Sons and Crisp, Ltd., on the 30th inst. Mr Lewis is establishing an agency, in his particular line, for the present.

PRICES FOR APPLES.

A new Order controlling the prices for Apples came into force on Tuesday last, with the provision that Apples and Pears sold and delivered by the grower before the 24th inst. may be sold without restrictions up to the 27th inst. For all Apples other than jam Apples the maximum prices on sales by the growers vary according to the month of delivery, as follows:—September, 1918, 45s. per cwt.; October, 50s.; November, 52s.; December, 55s.; January, 1919, 61s.; February, 70s.; March and onward, 75s. The maximum prices per lb. on a sale by retail are as follows, according to the month of delivery:—September, 7d.; October, 8d.; November, 8d.; December and January, 9d.; February, March, and onward, 11d. Where Apples are sold by a seller to a purchaser in quantities exceeding 20 lb. at any time or in any one week the retail prices are to be reduced by ½d. per lb. If the quantities sold at any one time or in any one week exceed 40 lb., the maximum prices are to be the same as on a sale by wholesale.

Answers to Correspondents.

Colleogynes and Pleiargoniums in Unheated Greenhouse: *L. L. J.* It is almost impossible to keep Cœlogynes in good condition through the winter in an unheated greenhouse. The Pelargoniums and Grevilleas may be kept safely provided means are taken to keep frost from them. We suggest the pots and pans containing plants be bedded in dry bracken and that similar material be placed lightly over the plants during cold weather, but removed whenever the weather is mild or when sunshine raises the temperature in the house above 40°. Watering must be done with the utmost care; the Cœlogynes will need very little, and the Pelargoniums hardly any water during the winter, and it should be applied only on a bright, warm day, and in early morning. A very little fire heat would suffice to keep the plants healthy.

Corn Cobs: *B. C. L.* Corn or Maize Cobs should be quite young when cut for cooking; if the seeds have ceased to be tender and "milky" the cobs are too old to be dealt with successfully in the ordinary way. The specimen received was too old for culinary use.

Diseased Pears: *H. H. E.* The disease is caused by a fungus, known as Brown Rot (Sclerotinia fructigena), a pest responsible for much damage in Pear and Apple orchards. Affected trees should be carefully inspected after leaf-fall. The removal and burning of all dead and cankered growth will be the first step towards a cure. Follow this by a spraying with Bordeaux mixture (4 lbs. quicklime, 4 lbs. copper sulphate, 50 gallons water) immediately before the flower buds open. In the case of a very bad attack, such as the specimens suggest, spray a second time as soon as the flowers have set their fruits.

Gardening Prospects in Tasmania and Queensland: *J. H.* For information concerning the prospects of fruit cultivation and market gardening in Tasmania and Queensland write to the Agents-General of these colonies, Australia House, Strand, London.

Names of Fruits: *Pomona.* Apple Worcester Pearmain.—*F. V.* 1, Not recognised; 2 and 4, Dumelow's Seedling; 3, probably Bramley's Seedling; 5, a form of Blenheim Pippin; 6, Worcester Pearmain.—*W. B.* Fruits immature, probably Beurré Clairgeau.—*J. and W. B.* Cox's Orange Pippin—a very fine specimen.—*R. D.* 1, Red Juneating; 2, King of the Pippins.—*A. D. P.* 1, Keswick Codlin; 3, Lord Grosvenor; 4 and 12, Ribston Pippin; 5, Tower of Glamnis; 6, Nonsuch; 7, Winter Strawberry; 8, Dean's Codlin; 11, Margil; 15, White Westling; 14, Potts's Seedling; 16 and 17, Lord Suffield; 18, Herefordshire Beefing; 19, Cellini; 20, Sturmer Pippin.—*T. W. B.* 1, Brockworth Park; 2, Beurré d' Amanlis; 3, Aston Town.—R. S. 1, Devonshire Quarrenden; 2, Irish Peach; 3, Alfriston; 4, not recognised; 5, Blenheim Pippin; 6, Duchess of Oldenburg; 7, Hanwell Souring; 8, Cox's Pomona; 9, Ecklinville Seedling; 10, Cellini; 11, Red Astrachan; 12, Golden Harvey.—*J. M.* Small's Admirable.—*F. W. S.* 1, Stone's (syn. Loddington); 2, Round Winter Nonsuch; 4, Red Hawthornden; 5, Sturmer Pippin; 8, Alfriston; 10, Gascoyne's Scarlet; 11, local variety; 12, Scarlet Nonpareil; 13, James Grieve; 14, Cox's Pomona; 15, Potts's Seedling.—*J. P.* 1, Smart's Prince Arthur; 2, Lady Henniker; 3, Warner's King; 4, Cox's Orange Pippin; 5, not recognised.—*S. B.* 1, Prince of Wales; 2, Black Diamond; 3, Prince Englebert.

Names of Plants: *W. M. M.* 1, Cattleya Loddigesii; 2, Cypripedium tonsum; 3, send another specimen.—*S. B.* Helenium autumnale.

Outdoor Tomatos: *M. S.* If the Tomatos were grown in pots all the season, but were placed out-of-doors as soon as danger from frost was over, without any other protection or aid than a wall or fence affords, the fruits therefrom would be as eligible for competition in a class for "Out-door Tomatos" as those produced by plants planted out of-doors in early June. This decision would, of course, apply equally whether the competition was organised by an Allotment Association or a Horticultural Society.

Potato for Naming: *H. E. B.* The variety is Up-to-Date.

Royal Horticultural Society's Examination: *D. McB.* Full particulars of the examination may be obtained on application (with stamped addressed envelope enclosed) from the Secretary, Royal Horticultural Society, Vincent Square, Westminster. The Society recommends certain books as especially useful for prospective candidates, and it will also supply lists of the questions set at previous examinations at a nominal charge.

Sale of Plums: *H. R. W.* The only Plums scheduled under the Plums Sales Order are the Pershore, or Egg Plum, Gisborne's, Blaisdon, and Bush or Mogul varieties.

Tomato Leaf Rust: *T. M.* Although the Tomatos may have suffered from attacks of the White Fly (Aleyrodes vaporariorum), the chief cause of damage is Leaf Mould or Leaf Rust, caused by the fungus known as Cladosporium fulvum. There is no cure at the present stage. Wherever this disease has appeared the young plants should be sprayed with weak Bordeaux mixture or a solution of potassium sulphide as a preventive measure, and the spraying should be continued at intervals until the fruits begin to ripen. Remove and burn all badly affected leaves, and ventilate the house freely to obtain a buoyant atmosphere.

Variegated Vine Leaves: *W. T.* The leaves on the small, lateral Vine shoots have not developed the usual green colour, and the yellow colouring mater, etiolin, gives the foliage a golden appearance. Such a condition is known as etiolation, and is common in nearly all cultivated plants. You would not be successful in perpetuating such a shoot entirely devoid of chlorophyll.

WATER-LILIES IN ST. VINCENT.*

ALL the streams in St. Vincent are swift running from mountain to sea, and the coastal lands are well raised above sea-level, consequently there are no swamps. Owing also to the light volcanic soil, pools retain water for short periods only, with the result that there are few striking flowering water plants. Attempts to introduce these plants into pools in rivers have not been successful, because the pools are so frequently washed out during heavy rains. So far as the writer is aware, the Water Lily Nymphaea rudis is found only in one small pond in the colony, and this dries up after the rainy season every year. Sporadic efforts have been made from time to time to grow aquatic plants in gardens, but these have not been viewed with favour by the sanitary authorities, owing to the fact that the tanks or tubs often served as breeding places for mosquitos. This disability, however, can be easily remedied now that a permanent source of supply of the "millions" fish is maintained in the Botanic Gardens.

In the year 1915 a large circular concrete basin or pond, 30 feet in diameter and 2 feet deep, was constructed in the gardens, in order that water plants, more particularly the true Water Lilies of the genera Nymphaea and Victoria might be cultivated.

The Water-Lilies, with the exception of the Victoria regia, are grown in tubs 14 inches high. Cement barrels sawn in halves have been found suitable for the purpose, as they do not readily rot under water. Even strong-growing Nymphaeas will thrive and flower freely in these tubs without it being found necessary to transplant them. Other advantages are: (a) the water of the pond can be kept fresh and clear, and free of decaying vegetable matter, and (b) the growth of individual plants can be controlled.

In preparing tubs for planting, holes are bored with a large auger in the bottoms, as well as around the sides, about 3 inches from the base. To ensure proper drainage, a layer of stones or broken crocks is placed inside the tubs, covering the holes, and on this is placed a layer of rotten wood. The soil mixture or compost used consists of good loam, cotton seed meal, and wood ashes, in the proportion of 10 : 2 : 1 by volume. This medium has given excellent results, and it has not been uncommon for a single plant to produce eight or nine flowers at one time, some of which have exceeded 12 inches in diameter. Before the cotton-seed meal and wood ashes were used, green filamentous algae, known as "moss," produced very unsightly effects in the pond each spring. Copper sulphate might perhaps have been used to control the algae, but for various reasons it was considered inadvisable to use it. Whether it was a mere coincidence or not has not been ascertained, still the fact remains that after using the above mixture the algae disappeared completely, and gave no further trouble. It may be added that other rich soil composts could be used for the tubs, or their composition varied to suit particular circumstances.

When planting the different kinds of Nymphaeas, small plants are selected from those which have grown up around the old flowering heads. Suckers are usually produced in considerable numbers in the N. Lotus and N. tuberosa hybrids and varieties that have been grown. One young plant of a strong-growing kind, and two or three of those less robust, are set in each tub just before it is submerged. Small tubers may also be used, especially of those varieties that have a distinct resting period each year even in presence of an abundant supply of water and a slight fall of a few degrees only in temperature.

For the Victoria regia, a bed is formed in the centre of the basin with the same soil mixture as described above. The soil is kept in position by means of a circle of large stones built up to the requisite height of 12 inches; this, as in the case of the Nymphaeas, allows of a maximum depth of water of 20 inches covering the soil, which is ample. Seedlings of the Lilies are raised annually from seed produced in the pond, not one of those is planted in the bed.

Tubers should be fully exposed to sunlight and sheltered from high winds. They require little attention subsequently, but it is necessary every week to take off exhausted or damaged leaves and flowers, in order to keep them in a healthy condition.

Hybridising of tuberous Water-Lilies is quite easy, and repays attention. Our experience has hitherto been confined to the raising of hybrids between N. Lotus and N. tuberosa, and we have already obtained some beautiful forms. These two species were selected, because 1, the diurnal movements of the floral organs were practically identical, and gave most promise of early success, and 2, because only a small number of seedlings could be tested at one time. It may be explained that certain groups of Nymphaeas flower by night, and others in the day. For example, the flowers of N. Lotus and N. tuberosa begin to open after dark, remain fully open all through the night, and commence to close soon after sunrise. They are quite closed by 10 a.m. Again, N. zanzibarensis starts to open about 9.30 a.m., remains fully open all day, and closes about 6 p.m. A variety of this species, N. zanzibarensis var. rosea, commences to open soon after sunrise, and closes about 5 p.m. Apart from the question of raising seedlings, it is important to note that unless the pond is visited before 10 a.m., or by moonlight, N. Lotus and N. tuberosa are not seen with open flowers, whereas the full beauty of N. zanzibarensis cannot be seen until after 10 a.m.

The flowers are frequented soon after sunrise by the honey bee (Apis mellifica). This is the chief insect visitor observed. Night flying insects have not yet been seen on the flowers. The honey bee does not confine itself to visiting flowers of one colour only, but has often been noticed to collect pollen from white, pink, and red flowers in succession. It is this fact which renders common the production of natural hybrids.

Owing to the limited facilities for handling seedlings, the practice is to allow only one or two flowers on selected plants to mature seed. All the other flowers, as soon as they have faded, are removed. It is often difficult to ascertain when the fruit is ripe, for after flowering the flower-stalk bends outwards and downwards, and submerges the fruit, which ripens under water or rather, gradually decays. When sufficiently decayed, the seeds are liberated. To each seed is attached a spongy mass of tissue filled with air, by means of which the seeds are enabled to float and are dispersed over the surface of the water. After a few hours the tissue loses the air, and the seeds sink. Some days later, provided the conditions are suitable, the seed germinates. The Victoria regia bed in the centre of the pond provides a suitable nidus, and it is usually possible to obtain an adequate number of seedlings from this source for testing purposes. At a very early stage seedlings can be recognised in respect of reds and whites, and there is in the species described a correlation between leaf and flower colour—that is, seedlings which will produce pink and red flowers have reddish-brown leaves of different shades, and those which will produce white flowers, green leaves. The distinction is noticeable in the first rosulate, sagittate, submerged leaves of the seedlings, and is very pronounced in the earliest floating ones. Seeds can, of course, be collected, and sown in pots or boxes under water, if desired.

On one occasion a fruit of a Zanzibar Lily, from which seed was specially desired for sowing, liberated its seed before it could be secured, and fortunately no other seeds were being germinated in the pond at the time. After a few days a large number of small seedlings, possessing one minute leaf and one or two fine roots only, with the seed still attached to the little plant, were discovered in various places. The seedlings were so small—less than ½ inch long—that they were difficult to handle. A novel method was devised in order to transplant them into boxes. The boxes were filled with sandy soil, and submerged in the positions they were to occupy. Then some clay was obtained, and rolled into small balls about the size of a playing marble. Each small seedling was then placed in the ball of clay, leaving only the small leaf exposed. The seedlings with their clay "sinkers" were then planted in the soil in the boxes under water, at distances of about an inch each way. This method proved successful, and the seedlings were successfully established.

When floating leaves have been formed, the selected seedlings are transferred to boxes large enough for them to produce a few flowers in. These boxes can be made conveniently out of an ordinary kerosene box, by sawing it in half, and boarding up the sides cut through. These boxes are prepared for the plants in a similar manner to that described in the case of the tubs. The seedlings will "declare" themselves in a few months, and then if they prove to be of sufficient interest they can be propagated vegetatively in the manner already described. The fact that most Water Lilies can be reproduced by vegetative means eliminates the difficulties usually met with in fixing hybrid plants that have to be grown from seed.

For the amateur with limited facilities it is suggested that a start might be made with the Nymphaeas named below; these are easy to grow, are robust, flower freely, and have not been found susceptible to disease:—

N. Lotus, var. dentata	..	large pure white.
N. hybrida	..	large light pink.
N. tuberosa, var. rosea		bright deep pink.
N. zanzibarensis	.. ..	intense blue.
N. zanzibarensis, var. rosea		heliotrope.
N. William Stone ..	..	blue.

The above named Lilies give charming floral displays. Several others might be named, and the list added to or modified, but, at the outset, most growers will find that these will meet their requirements.

Although the percentage of natural hybrids from probably impure varieties is always open to question, and cannot be exactly given, yet several excellent hybrids have been raised

* From the *Agricultural News*, July 27, 1918, by Mr. W. N. Sands, Agricultural Superintendent, St. Vincent.

ORCHID NOTES AND GLEANINGS.

CATTLEYA VENUS THE KNOWLE VARIETY.

Cattleya Venus, the result of crossing C. Iris (Dowiana aurea × labiata) and C. Dowiana aurea, was first flowered in 1908, the second cross with C. Dowiana infusing exceptionally bright colour into its flowers and perfecting the floral segments. But although there has been variation in the form of the flowers the dominating influence of C. labiata so strongly evidenced in C. Iris is in the main carried on to the varieties of C. Venus, the departure to the complicated the cross the greater is the variation, but, throughout all, definite sectional type species, such as C. labiata, most tenaciously assert themselves, the continuation of their features being determined on the fertilisation of the individual ovule in more or less quantity and degree even in the most remote ancestry. Garden efforts, useful as they are, give a very limited means of elucidating the mysteries of hybrid Orchids. Of the innumerable seeds in a capsule only a small proportion is sown; in most cases a further reduction is made in raising and bringing the plants to maturity, and thus even in the most satisfactory crosses possibly the best novelties were included in those discarded.

The flower of Cattleya Venus The Knowle

Fig. 50.—Cattleya Venus The Knowle variety.

type indicating the form of labellum as in C. Dowiana, being less frequent than would be expected from the second introduction of that species into its composition.

In C. Golden King (Venus × C. Hardyana) and C. Aconcagua (Venus × Dowiana aurea), however, the third introduction of C. Dowiana gives a more general Dowiana character to the lip, and even the individuality of that very distinct C. labiata C. labiata, in the manner shown by all the normal types still occasionally appears. On the contrary, C. Iris Venus Trist seems to have reverted in form to C. labiata even more definitely than C. Iris, though the colouring of Venus asserts itself.

These and many other instances of the vagaries of hybrid Orchids show that the more variety (see fig. 50), sent by John Hartley, Esq., The Knowle, Morley, Yorkshire, gives an excellent example of a fortunate hybrid perfected by good cultivation, and amply proves the correctness of the award of a First-class Certificate by the Manchester and North of England Orchid Society on September 20, 1917. The sepals and petals are 5 inches across, and of the colour of old gold, with a slight bronze shade and lighter midribs on the inner halves. The lip has a broadly expanded magenta-crimson front lobe, which is wavy and fimbriated at the margin. The short side lobes are coloured, like the petals, with rose-coloured lo nched lines on the inner side. The centre of the lip has a deep ruby-red tint and a few yellow lines. The column is fleshy and white.

THE ROSARY.

POLYANTHA ROSE JESSIE.

This, the brightest of Polyantha Roses, has with me two serious defects. In the first place its foliage soon loses its freshness, so that by August the leaves produced with the first bloom sprays are blotchy and ragged, soon withering and falling. The plants thus, though they may send forth secondary and tertiary clusters of bloom, present a bare and unhappy appearance through the autumn. The foliage has the appearance rather as if it were suffering from the fungous disease known as "leaf scorch." During the late spring and early summer of last year a small bed of this variety was sprayed regularly with a fungicide (potassium sulphide solution, with soft soap), but with no apparent beneficial result; the foliage was as badly affected as that of this year with no spraying. A plant of Orleans Polyantha Rose growing in proximity has not suffered in this way. Its early-produced foliage is still green, and functional at this late date.

The other defect is rather curious, and one which I have not observed before in Roses. The flower-buds of three out of the ten plants I possess refuse to expand. The buds swell to full size and seem just on the point of bursting, but never open, no matter what may be the state of the weather. They refuse to open when the sprays are cut and placed in water, cold or warm, or even when put in a heated room. These plants have been observed to behave in this manner during hot seasons, so the defect seems inherent.

It would be interesting to know if other Rose growers are having, or have had, similar experiences with this popular Polyantha Rose. Is it a case of a variety, vigorous at first, rapidly losing its robustness? It was introduced, I believe, barely ten years ago. *J. P. Carlisle.*

HARDY FLOWER BORDER.

MALVA ALCEA FASTIGIATA.

Under the name of Malva Morenii a good plant is being grown in some gardens known to the writer as well as in his own. It is, however, according to modern authorities, Malva Alcea fastigiata. The plant is a perennial, some 2 or 3 feet high, flowering from July to October, and my specimens are still in bloom. The flowers are a warm rose-red colour, and are both attractive and plentiful for the considerable period over which they are produced. This plant apparently grows best in a dry soil, for it appears to suffer no hardships in dry weather, and also withstands our winters satisfactorily. It is a native of Italy, and is figured in *Bot. Mag.*, t. 2793.

ACONITUM NEUBERGENSE.

Looking through one of Mrs. Loudon's books (*The Ladies' Flower Garden of Ornamental Perennials*) recently in search of certain information not to be found everywhere but often enshrined in some of the older gardening books, I came upon a reference to Aconitum neubergense, as distinct from A. Napellus, to which it is referred by the *Index Kewensis*. I am seeking information regarding what appears to have been a distinct species or variety, as described by Mrs. Loudon, but not illustrated in the coloured plate which delineates several of the other Monkshoods. Mrs. Loudon writes of A. neubergense that it is "often confounded with the common kind; but it differs in several respects. The flower is much longer, and it resembles rather a lady's head-dress in the beginning of the last century, with a high cap and pinners, than a monk's hood." I cannot recollect any Aconitum answering to this description. According to Mrs. Loudon's list of synonyms A. neubergense Clus. is synonymous with A.

Napellus, Jacq.; A. neomontanum, Wulf; A. cammarum, var. B. Linn., and A. Braunii, Rchb. This synonymy is not, however, in accord with the *Index Kewensis*. *S. Arnott.*

NOTES ON CONIFERS.

XX.—ABIES FIRMA.*

This well-known Conifer, the Momi of the Japanese, is the only Fir found in the southern islands of Japan, where it attains a large size on the plains. Wilson describes it as a noble tree with massive branches spreading horizontally and forming an oval or flattened crown. In the humid valleys of the south it reaches a height of 120 feet, with a stem up to 18 feet in girth. It is frequently planted in temple grounds, where it sometimes attains a height of 150 feet. It appears to have been first noticed in Japan by Thunberg, the pupil of Linnæus, who mistook it for the common Silver Fir, A. pectinata, and it was not until many years afterwards that it was recognised as new by Siebold and Zuccarini and described by them from cultivated examples collected by Siebold near Tokio. These authors afterwards described this same Fir under the name of A. Mildii, believing it to be distinct from their A. firma, but Dr. Masters† showed pretty conclusively that the two are merely stages of one species.

Abies firma is easily distinguished from the other Japanese species in cultivation by its bright green, coriaceous foliage, each leaf being tipped by two minute cartilaginous points which are easily visible through a lens. The young shoots are described as pubescent in the grooves, but this character cannot always be relied upon as a determining mark of the species, for I have seen specimens of undoubted A. firma in which the branchlets were almost entirely glabrous.

This is one of the Conifers introduced by J. H. Veitch in 1861, but it is stated that Maries, one of the Veitchian collectors, also sent home seeds of it in 1879. Although perfectly hardy, it is not common in cultivation, and no very large trees of it are on record. One of the best examples I know of is in Lord Derby's famous collection at Tortworth which has attained a height of about 60 feet and is about 6 feet in girth‡. There are several good specimens in Cornwall, one of the best being at Carclew. This was reported in 1891 to be 45 feet by 2 feet 8 inches. When measured by Elwes eleven years later it was 60 feet by 4 feet. In 1903 I made it 61 feet by 4 feet 10 inches§. A tree at High Canons, Hertfordshire, bore cones in 1907 and measured 47 feet by 3 feet 6 inches. Bean¶ mentions a tree 4 feet 6 inches in girth in the arboretum at Tregrehan, but does not state its height.

A specimen at Highnam Court, Gloucester, was 39 feet by 3 feet 9 inches in 1908. The tree at Woburn, illustrated in fig. 52, is a small one; it measured 29 feet by 2 feet 4 inches in 1915, when it coned (see fig. 51). It appears to be making good growth. The date of planting is not recorded. A tree at Bayfordbury, Hertfordshire, was 31 feet high by 1 foot 10 inches in girth in 1909. Other trees mentioned by Elwes are at Bagshot Park, 36 feet by 3 feet 11 inches in 1907, and planted in 1880; in Scotland, at Castle Kennedy, 44 feet by 5 feet 5 inches in 1904; at Munches, Dalbeattie, 30 feet by 2 feet 6 inches; and in Ireland, at Fota, 25 feet high and coning in 1907; Hamwood, Co. Meath, 36 feet by 2 feet 10 inches in 1904; and at Powerscourt, a tree 39 feet by 3 feet 11 inches in 1906 (coning). I shall be glad to have up-to-date dimensions of these or any other trees. *H. Bruce Jackson, The Avenue, Kew.*

BULB GARDEN.

LILIUM CANDIDUM SEEDING.

Mr. E. Dowsett, Ravenshill, Lechlade, Gloucestershire, writes:—"With regard to a query in a recent number of the *Gardeners' Chronicle*, whether L. candidum produces seed in this country, I have found that plants in pots and under glass readily form seed pods, which sometimes attain to very good size. I once raised a few seedlings, but they grew very slowly, and I finally lost them. In 1914 L. excelsum also produced about twenty apparently good seeds, but I never could find they germinated. I have found a few L. candidum under glass in over-attacked by Botrytis, even if the plants were badly affected the previous year. I think the reason may be that the foliage of the indoor plants is quite dry, and it could not suffer from spring frosts; also the growth is made earlier in the year when the Botrytis is dormant."

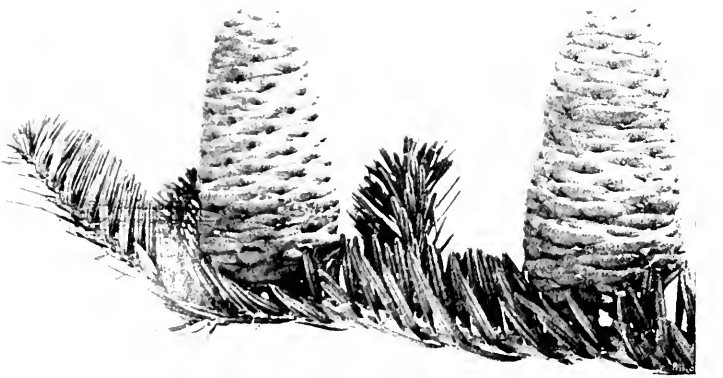

Fig. 51.—CONES OF ABIES FIRMA.

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables in *Gardeners' Chronicle* for August 3, p. 42.)

(*Continued from p.* 128.)

ENGLAND, S.W.

Herefordshire.—We had the best crop of Pears I have seen on Zéphirin Grégoire and Louise Bonne of Jersey, but took them all not more than one or two Pears on a tree. Plums of many sorts are free of any fruit; in place, Victoria and Belle de Louvain have a few odd fruits. Apples are probably yielding not more than one-eighth to one-tenth of a crop all round. In my own garden Ribston Pippin, Claygate Pearmain, and Cox's Pomona have moderate crops. Bramley's Seedling, Devonshire Quarrenden, and Golden Noble are quite bare of fruit. Plums are badly affected by leaf-curl aphis, and the mealy aphis appeared early in June in large numbers, especially on Victoria and Gage Plums. The rare Apple-leaf sawfly caterpillar appeared on two or three small Apple trees in my garden, but I have not heard of it elsewhere. *Dr. H. E. Durham, Dunelm, Eyot Hill, Hereford.*

Monmouthshire.—Apple trees blossomed freely, but the fruits set badly, and the blossom weevil was very prevalent. There was a great scarcity of Pear blossom, and few varieties have any fruit. Plums of all varieties are almost entirely without fruit. Cherries yielded light crops. Small fruits, including Strawberries, gave average crops, although they suffered from want of rain. There was a great dearth of catkins on Cobnuts, which accounts for a very light crop. The soil is heavy, resting on clay marl. *Thos. Coomber, The Hendre Gardens, Monmouth.*

Somersetshire.—Apples, Pears, and Plums generally are complete failures. Apple King of the Pippins and Plum Victoria being the only exceptions. Gooseberries and Red Currants yielded average crops of very good quality. Black Currants were a very poor crop. Raspberries and Strawberries promised well, but owing to continued dry weather the later berries failed to swell and ripen. Cider Apples are very scarce. Morgan Sweets only carrying a fair crop, even on trees that did not bear last year. This variety usually fruits in alternate years. Apricots, Peaches, and Nectarines are yielding very good crops. Figs on outside walls are also promising well. *George Shoesby, Halswell Park Gardens, Bridgwater.*

Worcestershire.—Apple and Pear crops are failures, with the exception of a few trees carrying very moderate crops. There was very little blossom on Pear trees, but an abundance on Apple trees. Caterpillars were plentiful, and may have had something to do with the failure. Strawberries yielded an average crop, of very good quality. Gooseberries and Currants bore freely. Our soil is a good, medium loam, resting on sandstone. *Ernest Avery, Finstall Park Gardens, Bromsgrove.*

The fruit crops are the poorest in my experience. The trees in most instances flowered well, but they did not set their fruits. Apple Ecklinville Pippin, which showed only a fair promise at flowering time is now completely bare of fruit. Pears are practically a failure. There are very few Plums except on trees of the variety Pershore. Morello Cherries promised well, but bore only a light crop. Other sorts of Cherries were poor and few. Peaches and Nectarines are yielding poorly; some trees have no fruits, and there are very few. Apricots. Raspberries would have been a heavy crop, but

the continued drought played havoc with them. Black and White Currants bore thin crops, but Red Currants were good on most varieties. Strawberries would have been a good crop if we had had more rain, but the fruits shrivelled up. The soil varies from good, light loam to sandy and marly clay. *T. Watkins, The Grange Gardens, Claines, near Worcester.*

—— Peaches, Nectarines, and Apricots are yielding abundant crops, whilst Apples, Pears, and Damsons are nearly failures. Plums are about half a crop. The above is general with only a very few exceptions. The month of March, when the first-named trees were in flower, was mild, dry, and sunny, which enabled the fruits to set perfectly. April, when the Apples, Pears, and Plums were in blossom, was stormy, cold, and sunless, therefore the pollen was never able to disperse. Rain and snow fell on 15 days. This is the worst Apple and Pear year we have had for thirty-five years. *William Crump, Madresfield Court Gardens, Malvern.*

—— The fruit trees generally throughout the county present a barren and an exhausted appearance. Small fruits have been fairly good in number but rather small in size, and, consequently, their weight has been considerably less than it would have been had there been more rain before the ripening period. *James Udale, 7, Ombersley Road, Droitwich.*

WALES.

CARDIGANSHIRE.—The Apple crop here is generally very poor, but some trees are bearing good crops, namely, Lord Grosvenor, King of the Pippins, Allington Pippin, and Worcester Pearmain. Pears are quite a failure, as most of them were in bloom when we had two very sharp frosts on April 15 and 19. Bramley's Seedling Apple trees were also cut by frost before the flowers opened. Certain varieties of Apples and Pears failed to flower. Black Currants and Gooseberries were very poor. Strawberries were very good, and Raspberries bore a fair crop. *Thomas Hazeldine, Crosswood Gardens.*

CARNARVONSHIRE.—Fruit crops generally in this district are very poor indeed, the worst known for many years. Apples and Pears are failures. Apple trees have been covered with caterpillars, some of the trees not having a leaf left on them. Bush fruits have given an average crop. The soil is gravelly, and crops feel the effects of drought very acutely. *J. S. Higgins, Glynlliron Gardens, near Carnarvon.*

DENBIGHSHIRE.—The fruit crops, with the exception of small fruits, are generally poor. Apples and Plums are yielding a thin crop, and Pears are a complete failure. Peaches and Apricots are bearing average crops. Strawberries cropped and finished well. *J. A. James, Chirk Castle Gardens.*

—— Pears this year were very short of bloom. Apples and Plums bloomed heavily, but owing to the cold, sunless weather, with a north wind, there was a very poor set. The trees also became infested with caterpillars. Apricots, Peaches, and Nectarines are bearing fair average crops. *John Martin, Bryn Estyn Gardens, Wrexham.*

FLINTSHIRE.—The fruit crops in these gardens are amongst the worst I have seen in 29 years. Apricots are yielding the best crop, although when they were in bloom 9° of frost were registered. There is also a very good crop of outside Figs. Strawberries were very deformed, which I attributed to the inclement weather through April. The fruit trees have been very much damaged by caterpillars. *James Barnard, Mostyn Hall Gardens, Mostyn.*

GLAMORGANSHIRE.—The Apple crop in this district is a very light one, with the exception of Lord Grosvenor, James Grieve, Charles Ross, and one or two other varieties, which are bearing very well. Cordon trees of Cox's Orange Pippin, Allington Pippin, and Pearson's Nonesuch are bearing good crops. Pears are almost a complete failure. Cherries were very good, especially the Morellos. Peaches and Nectarines are much below the average. Strawberries yielded a good crop, and the fruit was especially fine. *C. T. Warmington, Penllergaer Gardens, Swansea.*

PEMBROKESHIRE.—Apples, Pears and Plums are very scarce this year: in fact, there are practically none. Currants and Gooseberries, on the contrary, gave heavy returns, and the quality was generally exceptionally good, although in some parts of the county the dry weather affected them to some extent. *T. H. Roberts, Slebech Park Gardens, Haverfordwest.*

RADNORSHIRE.—Apples, Pears, and Plums are almost complete failures this year. Nuts appear to be about an average crop. Small fruits are also an average number, but rather small, and lacking in flavour on account of the drought. Raspberries being the best, with a fairly heavy crop. Blackberries are a promising crop, and no doubt will be much sought after owing to the failure of other fruits. *J. MacCormack, Macllwch Castle Gardens, Glasbury.*

IRELAND, N.

DOWN.—Certain varieties of Apples are giving good crops, notably Emneth Early, Grenadier, Warner's King, Golden Spire, Lord Suffield, Stirling Castle, Small's Admirable, Lane's Prince Albert, Bramley's Seedling, Gladstone, Lady Sudeley, Worcester Pearmain, James Grieve, Rival, Allington Pippin, and Ribston Pippin. The only Pears with any quantity of fruit are Williams' Bon Chrétien, Beurré Hardy, Doyenné du Comice, and Le Lectier. The Czar, Victoria, and Pond's Seedling are the only Plums with clusters of fruit. Strawberries have had a good season. All varieties did well, and gathering in quantity commenced in the second week of June. *T. W. Bolas, Mount Stewart, Newtownards.*

MAYO.—All fruits are very fair this year with the exception of Apples and Pears, which were destroyed by a heavy storm at the end of May. The soil is clayey loam. *Richard Joyce, Westport House Gardens, Westport.*

TYRONE.—The fruit crops in this neighbourhood are on the whole fairly satisfactory with the exception of Plums. Pears are very partial; some varieties (notably Williams' Bon Chrétien) are carrying very heavy crops, but late sorts are, as a rule, very scarce. Small fruits were all good, especially Black Currants and Gooseberries. Caterpillars have been troublesome on Red and White Currants, and to a less extent on Gooseberries, otherwise insect pests have not been unusually numerous. A heavy storm on June 9 did considerable damage in exposed situations, breaking the young growth and stripping off the young, tender foliage. *Fred W. Walker, Sion House Gardens, Sion Mills.*

IRELAND, S.

CORK.—Apple trees bloomed fairly well, but cold winds and frosts in May completely destroyed the blossom. The Pear crop is a complete failure. A large number of Apple trees are suffering from American blight, and Gooseberries are badly attacked by caterpillars. The exceptional drought prevented Raspberries and Strawberries from swelling properly, and numbers of Apples are falling from the same cause. Altogether the fruit prospect is the worst for many years. *M. Colbert, Aghern Gardens, Conna.*

——All fruits blossomed freely except Pears. Generally speaking, however, the bloom appeared to be weak, particularly on trees that gave a heavy crop last year. Strawberries and all bush fruits promised well in the early part of the season, but as a result of the cold nights, harsh winds, and prolonged drought during May, June, and the early part of July, all crops were below the average with the exception of Gooseberries. On dry soils practically all bush fruits were a failure. *J. Dearnaley, 17, St. Patrick's Terrace, Magazine Road, Cork.*

(To be concluded.)

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Digging Vacant Ground.—Up to the present all well-managed gardens will have been kept closely cropped, but now Peas, Beans, Cauliflowers, and various other root crops are being cleared. There is not much available labour for trenching, but deep digging will improve the ground should deeper cultivation be impossible. Those who find that their ground can be most readily sown or planted directly after digging are quite justified in deferring the work of digging until the spring. The peculiarities of each particular garden have to be studied by those in charge, and no general rule can be laid down. The majority of soils might, with advantage, be dug in the autumn, and especially would I recommend that as much trenching as possible be done each season. Much wheeling of manure may be done with advantage during a dry time in October instead of waiting until frost has hardened the surface. Strawy or comparatively fresh stable manure is best for heavy land, and it should be applied in advance of the cropping season, whereas cow or mixed farmyard manure is to be recommended for light soils. Vegetable rubbish accumulates rapidly at this season, and if properly treated and returned to the garden will prove excellent material for many crops. Charred and burnt refuse is of the greatest value for lightening the ground prior to seed sowing, and greatly assists stiff soil to become more productive.

Carrots. Carrots growing in cold, wet soils should be taken up and stored, as an excess of moisture at this season would cause many of the roots to split, especially if much rain falls after a period of fine weather. Store the roots in a cool, moist position in sand or ashes in a cool shed, or in ridge-shaped heaps in a cool, sheltered situation out-of-doors. Handle the roots carefully and do not bruise them; arrange them in layers with the crowns outwards. The sides should be covered with soil to a depth of 6 inches, and the roots should be further protected in severe weather with a little straw or bracken. In this way Carrots will keep good until late in the spring.

Beet.—These roots should be lifted carefully without breaking them, and stored in a similar manner to Carrots before severe frosts are expected: Beets are more tender than Carrots. The tops should be twisted off, and not severed with a knife.

Globe Artichoke.—Remove all old stems and rough leaves from Globe Artichokes and break up the ground between the rows. Protect the roots in very cold weather with long litter or bracken.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Seasonable Remarks.—Every effort should be made to secure the thorough ripening of the growths and pseudo-bulbs of the plants in each division, by removing the permanent shading and by reducing the interval between lowering and rolling up the blinds. It is impossible to give precise directions on the subject of shading, for much depends on the kind of plants grown. In any case, the reduction should be gradual, the object being to cause the foliage to become hardened, so that little shading will be necessary after the middle of the present month. The amount of moisture in the atmosphere should be regulated with extra care until after fire-heat is more extensively employed. The cooler houses will require damping the least, because there will be less evaporation in these structures. In the warmer houses sufficient atmospheric moisture must be promoted to counteract the effects of fire-heat. The East Indian, Cattleya, and Mexican houses will require to be damped on mornings and afternoons.

while the intermediate and cool houses, in which very little fire-heat is employed at present, should be damped only in the mornings, except on bright days, when the paths and stages should be sprinkled in the afternoon. Watering and spraying the plants must be carried out according to their various stages of development, with due regard to the weather, while the compost used also makes a great difference in the amount of moisture required. Plants with pseudobulbs nearly completed should receive a gradually diminishing supply, but water must not be withheld to such an extent as to cause shrivelling, whilst plants that are still in active growth should be afforded an adequate supply of moisture.

Fire-heat and Ventilation.—As the nights become colder it will be necessary to provide extra fire-heat; on warm days the ventilators should be opened slightly to prevent scorching of the foliage, but retain as much sun-heat as is practicable. A cool, damp autumn is most suited to Odontoglossums, and the plants are developing vigorous growths. The houses in which they are grown should be ventilated very carefully at this season; the air should be admitted through the bottom ventilators, regulating the amount at all times in accordance with the outside temperature. During warm nights the top ventilators may be opened slightly to admit the autumn dews that are very beneficial to Odont. flowering, and especially those that have been freshly potted.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

Early Pruning, and Cleansing of Trees. This work should be done earlier than usual this autumn; it will not be too soon to commence immediately the leaves begin to fall. Start with the pruning and get this work done as quickly as possible. Afterwards proceed with the dressing of the trees, where needed, against insect pests. American Blight was probably never so troublesome as this year, and strong measures will have to be taken to destroy this pest. A wash may be made of 4 oz. of soft soap to 1½ gallon of hot water; this steeds is penetrating and effectual. I intend to give a trial later to a wash made of 2 lbs. of caustic soda (98 per cent.) in 10 gallons of water. Paraffin emulsion is another good remedy; it is made of 1 gallon of paraffin, 1½ lb. soft soap, and 10 gallons of water; this wash is suitable for use in winter only. Lose no time, now that October is here, to renew the grease proof bands against the Winter Moth. These can be purchased at a nominal figure in readiness for use, and are easy of application. When these are carefully fixed apply the grease prepared for the purpose, and renew it as may be found desirable. Clear all fallen leaves from round the trees and lightly remove the surface soil, then apply some freshly-slaked lime, adding a light dressing of fresh soil. If American Blight is suspected of having attacked the roots apply a soil steriliser and use this as recommended by the makers.

Alpine Strawberries.—New plantations of Alpine Strawberries should be made as early in October as possible. Let the plot that is allotted to these fruits be trenched and manured, but not necessarily with strong dung; nothing is better than well-decayed leaves. Let the ground be well broken up in the process of trenching. Proceed to plant the young stock as soon as possible after having trodden the ground and raked the surface level. Where Strawberries grow freely allow 2 feet between the rows and 1½ foot between the plants. Water them at once and rake over the ground. Remove any runners that have developed, and plant them with a good ball of soil at the roots.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Dielytra spectabilis.—This is a most useful plant for forcing, and requires very little fire-heat. Place the clumps in 7-inch or 8-inch pots, water them thoroughly, and plunge them in ashes out-of-doors till growth commences. The plants should then be brought into a light, airy greenhouse and placed near the roof-glass.

Chrysanthemums. — Plants needing disbudding should be gone over regularly, removing the side buds when they are large enough to handle. The pots are filled with roots, and strict attention to watering is of great importance. The plants are also in need of plenty of stimulants till the flowers are expanded. Houses containing Chrysanthemums which are developing their flowers should be kept dry, or many of the blooms will damp, and especially the large show varieties. Stimulants should be withheld from these large flowering plants when the blooms are expanding.

Campanula pyramidalis. Young plants of the Chimney Campanula which are sufficiently well rooted should be potted without further delay. Older plants should also be repotted if necessary. Plunge the pots in a bed of ashes in a cold frame, and water the roots very sparingly for the present. Admit an abundance of air whenever the temperature is above freezing point, for a close atmosphere would cause the loss of much of the foliage. The lights may be removed entirely during favourable weather.

Primula.—The latest plants of greenhouse Primulas should be potted as soon as they are ready for this operation. Place them in 5-inch pots, and use a light, open compost. Stand the plants when potted on a shelf or stage near the roof-glass in a shallow pit for preference. Use fire-heat sparingly at all times. Should severe frosts threaten cover the glass with mats. The earliest plants should be well rooted, and a little weak manure may be given them once or twice weekly.

FRUITS UNDER GLASS.

By W. J. GRIST, Gardener to Mrs. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

Early Vines. In most gardens early Vines were started after Christmas this season, and earlier instructions on that will again prolong the resting season. For these reasons it is not advisable to prune the vines freely until they have quite cast their foliage. In the meantime all laterals should be cut well back, taking care to leave a reasonable length of the ripened wood with the main leaves intact, these being necessary to feed and perfect the buds for next year's fruiting. The roots of vines in inside borders should not suffer for want of moisture; on the contrary, it is advisable to protect outside borders from excessive rains. Ventilate the house both day and night, and dispense with fire-heat entirely.

Late Grapes. Late Grapes should be ripe and the temperature of the vinery should be lowered but kept steady. With shortening days and declining sun-heat fire-heat will be necessary to assist Grapes to finish their ripening, for unless the bunches are well finished during the next week or so there will be some difficulty in keeping them in good condition during the winter. A brisk temperature and dry atmosphere (the more air in reason through the early part of the day) are the two essentials to well-finished bunches; moreover, this treatment will be of material assistance in thoroughly ripening the wood. If not already done, all lateral growths should be removed, that the main foliage may have every ray of light. Care must be taken not to rub the bloom off the bunches when removing dead leaves or decaying berries. Any necessary watering or damping should be done early in the day, when ventilation and fire-heat are sufficient to dry all moisture. A lower night temperature may follow with safety, provided the atmosphere of the house is quite dry. Excessive rainfall in some districts makes it necessary to cover outside borders with galvanised iron sheets or other material. If the inside borders are dry there should be no hesitation in giving the roots just sufficient water to keep the vines active until the Grapes are cut, but the watering must be done in the forenoon of a bright day, for on no account should the house be closed with sun-heat and moisture, to cause condensation of moisture on and consequent sweating of the berries.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Lymingtame, East Lothian.

Late Cuttings.—One cannot make too much of Violas, Nepeta Mussini, Lavender, and Pentstemons in these stressful times, and cuttings of all of them dibbled into light, sandy soil in cold frames will root freely, and be ready for planting permanently by next April. Usually no watering will keep the soil in good condition until February, but a light shading is desirable for a week or two during the middle of each fine day. Cuttings of Carnation Ruby Castle, still one of the best bedding varieties—may be propagated similarly, and the variety Duchess of Fife roots freely treated in the same manner.

Rose Cuttings. The Wichuraiana section and some of the old-fashioned kinds of Roses are easily increased by cuttings inserted in the open ground at this time. Matured shoots a foot in length should be selected, broken off with a heel, and inserted quite 6 inches in depth. They should be made thoroughly firm in the soil, and hen ordinary frost will loosen their hold. Where the lovely Rosa hemisphærica succeeds, and is on its own roots, suckers may now be detached and planted in beds, but without cutting back the tops, though long roots should be shortened.

Planting Shrubs. Any shrubs that have been prepared for transplanting should be moved without delay, and afterwards young or nursery stock should have similar attention. Shrubs properly planted about this time of year require no attention in the future to induce them to live, which, apart from a great saving of labour, also saves worry. If the soil is dry a soaking of water will be of great advantage, and, of course, all shrubs large enough to suffer from wind storms must be staked, large ones needing three stakes, inserted at an angle and meeting together at the stem of the plant.

THE APIARY.

By CHLORIS.

Winter Trouble. During the winter those who have not painted their hives thoroughly during the autumn may find leaks in the roof after continued stormy weather. They may be dealt with as follows: Remove the roofs occasionally after heavy rains, and having located the leak rub in with a paint brush gold size, which can usually be purchased at the colour shops. If the crack be wide stop with putty or white lead, and then stretch a piece of calico over it and paint with gold size until better weather prevails. All quilts which have been wetted by rains should be removed, and replaced by dry ones. For warmth, as a winter wrapping after putting on good fitting quilts with a sheet of brown paper between the two layers of quilts, put on a cushion lightly filled with shavings, dry leaves, Corn husks, or cork dust, and the bees should be very cosy during the most trying weather.

Overhauling. All tools used in the apiary should be carefully overhauled before putting them away, and veils, smokers, and utensils repaired so that all may be in readiness for another season. Those who have time and wood may be usefully employed during the coming winter in making new hives, new sections, and shallow frame racks; those who are not so capable in handiwork and desire to enlarge their apiary next year, should place orders for new hives with the makers to ensure an early delivery. Those who can do so will be wise if they fit up sections and frames with foundation in readiness for next year, as those prepared now will be more perfectly done than those which are attended to in the busy season. Those who adopted the system of note making during the busy time will readily admit the need of early preparation, for experience will have taught them its value. Many mistakes would be avoided if a notebook were kept, and the hint jotted down when discovered, besides becoming a valuable guide in years to come, because it is surprising how soon one forgets a valuable idea when the need for its use has passed.

EDITORIAL NOTICE.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR OCTOBER.

MONDAY, OCTOBER 7—
Nat. Chrys. Soc. Floral Com. meet at Essex Hall, Essex Street, Strand

TUESDAY, OCTOBER 8—
Royal Hort. Soc. Com. meet. R.H.S. Exhibition of British-grown Fruits. Horticultural Club, luncheon, 1 p.m.

MONDAY, OCTOBER 14—
United Hort. B. & P. Soc. Com. meet

TUESDAY, OCTOBER 15—
Brighton, Hove, and Sussex Hort. and Food Production Soc. Fruit and Vegetable Exhibition at Royal Aquarium, Brighton (four days). Croydon Hort. Mutual Imp. Soc. meet. Southampton Roy. Hort. Soc. Autumn (Food Production) Show (two days).

MONDAY, OCTOBER 21—
Nat. Chrys. Soc. Floral Com. meet at Essex Hall, Essex Street, Strand; Exec. Com. meet., 35, Wellington Street, Covent Garden.

TUESDAY, OCTOBER 22—
Royal Hort. Soc. Coms. meet

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 51.5°.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, October 2, 10 a.m.: Bar. 30.2, temp. 52°. Weather Slight rain

SALES FOR THE ENSUING WEEK.

TUESDAY—
Clearance sale of Greenhouses, Piping, Vans, and other effects, at The Nurseries, Hall Green, Birmingham, at 12 o'clock.

WEDNESDAY—
Sale of Bulbs at 67-68, Cheapside, at 1 o'clock.

Grow More Fruit.

The failures of the present year's fruit crops are likely to be remembered long both by those who grow fruit and those who do not. The former have suffered from poor crops and controlled prices, and the latter have had to pay dearly for any fruit which they were able to buy. It is not the intention of this article to discuss the difficulties and hardships with which the grower of fruit has this year had to contend, but rather to urge the importance of growing more fruit by all those who have the land and labour to spar for this purpose. There can be little doubt but that all the fruit which we can produce will be wanted during the next few years. The shortage of tonnage, which will persist for some time after the war, will mean that the home grower is not likely to be handicapped by large competition from abroad; and the fact that considerable numbers of pulping stations have been established in different parts of the country should offer some guarantee to the grower than even if we have bountiful fruit harvests in the coming year there will be less wastage than has hitherto been the case. Manifestly there are two ways in which more fruit may be secured. One is to ensure a larger yield, by careful treatment of existing plantations; and the other, of course, is to increase the acreage under fruit.

We have already urged the desirability of the increased planting of Strawberries and of Raspberries, and we believe that the Food Production Department has addressed a memorandum on this subject to Agricultural Executive Committees commending to those bodies the desirability of encouraging the planting of quick-yielding fruits. Needless to say, the shortage of labour makes it difficult for market fruit growers to do much in the direction of increasing acreage; but now that they know that the county authority responsible for supervising food production is prepared to encourage in lieu of discouraging fruit production, it is to be hoped that they will do all they can to meet the nation's requirements in this respect.

With regard to the former of the two ways already mentioned of increasing production—by careful attention to existing plantations—it cannot be gainsaid that controllable pests and diseases are more prevalent than they should be, and that they were in no small part responsible for some of the failures of the past year. Those, for example, who took the precaution to spray with arsenate of lead in the spring of this year have, at all events in numerous cases which have come under our notice, reaped an exceeding rich reward. Grease-banding—which should be completed by the end of the first week in October—is not practised as generally as it should be, and yet in the case of standard and half-standard trees it is a measure of prevention of caterpillar attack which cannot be neglected with impunity.

The spread of Silver Leaf disease in Plums, and the widespread ignorance of the symptoms and seriousness of the disease, are calculated, if not arrested and corrected, to reduce the Plum harvest very considerably. At the present time it is not easy in some districts to find a garden entirely free from Silver Leaf, and we ourselves have seen many hundreds of affected trees the owners of which were unaware of the nature of the disease from which the trees were suffering, or of the importance of cutting diseased branches back to healthy wood.

Owing to the large numbers of gardeners now serving with H.M. Forces, the standard of cultivation in gardens is standard of cultivation in gardens is bound to be lower than it was in peacetime, and hence it behoves everyone who can preach the gospel of "keeping orchards clean" to do so.

The Food Production Department has recently appointed a number of experienced fruit growers to undertake propaganda work on this subject, and we learn with pleasure that this step is being welcomed by professional growers, who thoroughly realise the need for raising the general standard of fruit cultivation in the country. The large growers, of course, need no instruction on the subject of orchard sanitation, but they are aware that the more general are the measures taken to control orchard pests the less will be the likelihood of epidemics of disease.

Lastly, owners of gardens who have had the misfortune to lose their more highly skilled men can do a good deal to secure better disease-control in their own gardens. The leaflets published by the Food Production Department on the means of controlling orchard pests give simple instructions, and by procuring these leaflets from the Board of Agriculture, studying them themselves, and handing them on to their improvised staff, they can spread valuable information, thereby assisting in increased fruit production.

Horticultural Club Luncheon.—Members intending to be present at the luncheon on the 8th inst. are asked to notify the hon. secretary, Mr. G. F. TINLEY, 41, Wellington Street, Strand. The luncheon will be held at 1 p.m. in the dining-room at 2, Whitehall Court, where the Horticultural Club now meets.

Sugar from Stevia Rebaudiana.—In the *Anales Cientificos Paraguayos* Dr. M. S. BERTONI gives an account of a very interesting plant named Stevia Rebaudiana, a somewhat rare species found in the highlands of San Pedro, Paraguay. It appears that the leaves of this Composite contain a property about 180 times sweeter than Cane sugar. This substance is unfermentable, has not the toxic effect of saccharine, and can probably be put on the market at a lower price than saccharine. It is not suggested nor anticipated that this sweetening material will take the place of Cane or Beet sugars, but it is expected to prove valuable for medical purposes. An interesting point is that the dried leaves retain their sweetening power indefinitely and may be used in a powdered condition.

Vitality of Gorse Seeds.—In an interesting letter to *Nature* Mr. J. PARKIN, The Gill, Brayton, Cumberland, writes: "Some forty acres of Gorse- and Heather-covered land situated near my home in the plain of Cumberland were drained, cleaned, and ploughed in 1893. This area was kept in arable rotation for a number of years; then part of it was laid down in grass in 1904, and the remainder in 1906. It soon became evident that this new pasture would rapidly revert to a Gorse-covered common unless drastic measures were taken to rid the ground of the numerous Gorse seedlings, which had sprung up from the seeds brought to the surface by the last ploughing. These were stubbed out, and in two or three years' time the ground was entirely free of Gorse plants, and has continued so for the ten or more years it has been allowed to remain in permanent pasture. Last winter this land was again brought under the plough by order of the local War Agricultural Committee, and was sown with Oats. The crop has now been reaped, and Gorse seedlings, 6 inches or more in height, are to be seen scattered over the stubble, being especially abundant where originally the Gorse grew strongest. Evidently, then, the last ploughing has brought to the surface a fresh lot of seed."

Importation of Plants and Seeds into British India.—The Department of Agriculture of the Government of India has, under the Destructive Insects and Pests Act, 1914, placed the following restrictions on the importation of certain plants and seeds into British India:—(1) No plant may be imported into British India by means of letter or sample post. (2) No plants except fruits and vegetables intended for consumption, no Potatos and no Sugar Cane may be imported into British India by sea except after fumigation with hydrocyanic acid at one of the following "prescribed ports"—Bombay, Calcutta, Dhaneshkhodi, Karachi, Madras, Negapatam, Tuticorin, and Rangoon. This provision

does not apply to plants imported under the special certificate of the Imperial Entomologist to the Government of India for experimental purposes. (3) Potatos imported into British India must be accompanied by a certificate from the consignor declaring the district and county of origin, and guaranteeing that no Wart Disease is known to exist on the land where the Potatos were grown; also by an official certificate that no case of Wart Disease of Potatos has been known to exist during the previous twelve months within five miles of the place of where the Potatos were grown. In the United Kingdom, the proper officer or authority for the issue of this certificate is the Board of Agriculture and Fisheries for England, or the Board of Agriculture for Scotland; and the Department of Agriculture and Technical Instruction for Ireland. The following rules for the disinfection of plants imported by sea into Calcutta have been issued by the Governor of Bengal in Council under the Destructive Insects and Pests Act, of 1914: (1) It shall be the duty of the Customs staff to conduct the operation of disinfection of plants at their entry at the port of Calcutta. (2) The fumigation of such plants by hydrocyanic acid gas shall be in accordance with the instructions received from the Imperial Entomologist, Pusa.

ON INCREASED FOOD PRODUCTION.

STORING VEGETABLES.

Certain root crops should be lifted and stored in autumn; others may remain in the ground until required for the table. The flavour of the Jerusalem Artichoke is retained better in the ground than under storage conditions. If a portion of the growing crop is covered with straw the roots may be lifted during times of severe frost. The Parsnip becomes bitter, tough and stringy if it is lifted and stored, and is therefore best left in the ground. If it is necessary to clear the ground of this crop the roots should be lifted and buried in sand at the base of a north wall or in some other cool situation. Potatos need to be stored in a frost-proof place, and should be lifted from the ground when ripe. After lifting, the tubers should be laid on the ground to dry for a day or two. Though it may not be absolutely necessary, it is certainly beneficial to store the tubers when they are dry. If a store pit or clamp is used the height of the tubers in the pit should not exceed 4 feet. A little freshly slaked lime worked in as the clamp is made will act as a deterrent to worms and woodlice, and help to keep the interior of the clamp in a sweet condition. Straw and soil are the materials used to exclude frost, light and water. Straw should be laid on the tubers to a thickness of about 4 inches. It is seldom necessary to place more than 4 inches of soil on the straw before Christmas. The most severe frosts occur in January and February, and more soil is then required to cover the clamp. In very wet districts it is advisable to conduct water from the clamp by means of a small gulley. Rats often do considerable damage in Potato pits. The usual methods of exterminating these pests should be employed, with the exception of poison. I do not think there is any better method of storing Onions than hanging them in ropes. Onions keep well in a frost-proof, dry structure. The bulbs should be thoroughly dry when harvested. The winters are so severe that Beet must be stored in northern districts. Great care should be employed in lifting this vegetable, as damage to the root-fibres causes bleeding and deterioration of quality. Beet keeps well in coarse sand; the roots and sand may be arranged in alternate layers, in an open shed. Do not cut off the tops, but remove them by twisting. This is a good but effective preventive of bleeding. Carrots may be stored successfully in the same conditions as those advised for Beet. Vegetables should be harvested in genial weather conditions. The work should be pushed forward on dry days, for I am certain from experience that crops keep much better when laid away dry.—*Geo. H. Copley, Hatton Park, Bradford.*

FINE CROPS OF POTATO KERR'S PINK.

Our local (Redditch) Horticultural Society's Potato-growing competition for cottagers and amateurs has again been an unqualified success, chief interest being centred in the class for the best crop obtained from 1 lb. of Kerr's Pink cut into twelve sets. The seed tubers were obtained from Edinburgh, carefully weighed, put into 1 lb. bags, and handed to the competitors early in the year. The crop was lifted and weighed on August 23. Mr. Levi White won 1st prize with 7½ lbs. ware size and 1 lb. small; the winner of the 2nd prize had 5¾ lbs. ware, 2½ lbs. small; the 3rd prize set gave 5¼ lbs. ware and 2 lbs. small, the latter including one diseased tuber, the only one seen during the course of a long and trying day's judging. Thirteen growers had crops of 6 or 5½ lbs. each from the pound of "seed." The twenty two competitors produced a total of 73½ lbs. ware size, and 22¼ lbs. small, the average crop being reduced by one crop giving 10¼ lbs. and another 19½ lbs.

Mr. Avery, of Finstall Park, who judged these competitions with me, was impressed with the small proportion of small tubers. Kerr's Pink is a good Potato, and crops and cooks well. The competitive Potatos were grown in a widely scattered area, some on light soils, some on heavy, so that the test was a fair one as regards the suitability of the variety for the district, but opinion among growers seemed divided some liking its appearance whilst others seemed to think it would not take the place of older varie-

Photograph by E. J. Wallis.

Fig. 62.—ABIES FIRMA AT WORDEN.—WHEN MEASURED IN 1911 THE TREE WAS 29 FEET HIGH. (See p. 147.)

ties. The habit of growth is quite distinct from all others, being very tall and upright. Some readers may suggest that the Potatos were lifted early, but the cottagers were anxious to get their crops lifted owing to wet weather following a long period of drought, and they were right, as second growth had already started except in three cases. The Potato crop in this locality is good, and very little disease has so far been observed. A similar competition last year made Great Scot popular in the district, and it figured largely in the plots grown for competition. Some growers complain that this variety is coarse and does not keep well; personally I have not found it so, for with me it has kept well until July.

Ten competed for the best 10-yard row of early Potatos, to be judged the first week in July, and this proved to be an interesting test as to the merits of close or wide planting. One grower had thirty-six sets in the 10 yards; another only fourteen. It was decided that the fairest way to judge this class was to count the roots or sets in each row, lift three roots, weigh the produce, and estimate the total weight. The winner had twenty-six sets, and the estimated crop was 48 lbs. ware size, 5½ lbs. small, variety Midlothian Early; the 2nd prize crop had fourteen sets, estimated crop 47 lbs. ware size, ½ lb. small, variety May Queen; 3rd, twenty-two sets, estimated crop 44 lbs. ware size, 6½ lbs. small, variety Midlothian Early. Sharpe's Express is scarcely early enough for this competition, but it is still one of the best of Potatos, if not the best, for cooking quality, and no early variety out of the many I have tested is equal to it in the third week of July. Multiplicity of varieties in a garden means increased work, and this is to be avoided in a time like the present.

Next season I shall grow for my earliest Webb's First Crop, followed by Sharpe's Express, Great Scot, Majestic, and Lochar. Kerr's Pink has such vigorous growth that I am just a bit dubious as to its suitability for garden cultivation. Majestic is in front of it. Epicure, as grown locally, is not worthy of its name. For some years I have relied on King Edward VII. for the main crop, and again this year it has cropped well, but unfortunately it has given us half a-dozen tubers affected with the wart disease, so I am afraid we shall have to discard it. This season has again demonstrated the value of Scotch seed in a remarkable way, for in nearly every case in which I have been consulted with regard to a failure or partial failure of the crops the cause could be traced to planting worn out sets. The extra cost of seed from the North is more than repaid by the increased yield. *James J. Graham, Hewell Gardens, Redditch.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Apples in Public Parks and Gardens.—To increase the production of home-grown fruit in the neighbourhood of towns, some corporations are planting fruit trees in those of their parks which are largely visited. Such an object-lesson cannot but do good. At Bournemouth the Corporation has planted both standard, trained, and bush-grown trees in groups and singly on the grass in the beautiful gardens in the centre of the town, where the progress of the trees can be watched. Apart from the educational side of the subject, there is a fascinating beauty in Apple trees when in full bloom, and also when laden with fruit, especially such varieties as Gascoyne's Scarlet Seedling and Worcester Pearmain. The planting at Bournemouth was placed in the hands of the able Parks Superintendent, Mr. Stevenson, who has had charge for thirty-two years. The natural soil and situation are not entirely favourable to fruit culture owing to the wet subsoil, but with his usual forethought Mr. Stevenson carefully prepared a station for each tree. Considering the trees were not planted until March their progress has been remarkably good, and they bid fair to be a success and prove an additional attraction to the numerous visitors. *E. Molyneux.*

"Rogues" among Potatos.—As my firm's name is mentioned by Mr. Jackson in his letter on p. 122, I am writing to say that Mr. Jackson sent us, in the autumn of 1916, some tubers which he said had been grown from a new variety he had raised, and which was the same about which he had had an interesting correspondence some years ago with Mr. Martin Sutton, who at that time was unable to identify the variety. These tubers were carefully planted in our trials side by side with several hundred other stocks, but the only note we were able to make was that the variety resembled Up-to-Date, and the crop was a very poor one. At the moment of writing I am unable to refer to any reports of trials made of tubers sent some years previously. My principal object, however, in writing, is to say that the quotation which Mr. Jackson gives from Darwin's *Variation of Animals and Plants under Domestication*, chapter 11, p. 410, absolutely confirms all that Mr. Cuthbertson said in his letter which appeared in the *Gardeners' Chronicle* for September 13, as the only instances which Darwin gives of bud variation are those which refer to the colour of the skin. All Potato growers of experience know perfectly well that certain sorts do produce variations in the colour of the skin, and that other examples, such as the Old Rector of Woodstock, which gave a Potato the skin of which was mottled purple and white, might also have been named. The fact remains that in all such cases there is no change whatever in the identity of the variety, and it would be absolutely impossible to distinguish the plant which bore tubers differing in colour from the original stock, if grown side by side under precisely the same treatment and from seed tubers grown on the same soil the preceding year. Not only would the haulm be absolutely identical, and the flowers (if flowers were produced), but the shape, texture, and yield of tubers also. Most of us remember the interest aroused some years ago by Monsieur Labergerie, who claimed that the wild Solanum Commersonii had given rise by bud-mutation to a large, coarse-growing red or violet skinned Potato, the crop of which I saw growing in the South of France, protected by a high fence, and guns so arranged that any attempt to enter the enclosure would fire them. The experiments, however, made by the late M. Philippe Vilmorin at Verrières, and by myself at Reading, prove conclusively that this so-called bud-mutation was nothing more or less than the Blue Giant introduced by Polsen in Germany, stray tubers of which had evidently found their way into Labergerie's garden. I also visited Professor Heckle's Trial Grounds at Marseilles in order to examine some of the "mutations" which he claimed to have raised from Solanum Commersonii with the aid, as I was informed, of liberal dressings of poultry manure, but it was not apparent that any of the so-called "mutations" had arisen under suitably controlled conditions. It is quite clear, moreover, from the instances which Darwin gives, that the only kind of bud-mutation he had in mind was that which gave a difference in colour of the skin of the tuber, and many of your readers may remember that the white sport from Fortyfold was always known as White Fortyfold, and the same held good with the white sport from Beauty of Hebron, which was always known as White Beauty of Hebron. *Arthur W. Sutton.*

Brunton, of Birmingham. — Among the several Trade Cards reproduced in the *Gardeners' Chronicle*, November 20, 1915, was one (p. 319) of J. A. Hunter, of Birmingham. Like most other Trade Cards, it had no date, but it obviously dated from the latter part of the eighteenth century. The recent publication of "A Catalogue of the Birmingham Collection" in the Public Library at Birmingham enables me to approximately date the Trade Card, for the library contains three Catalogues of the firm. The earliest of these is a "Catalogue of Plants, Botanically Arranged According to the System of Linnæus"; it was issued by John Brunton and Co., 83, High Street, Birmingham, 1777. The second was one of forest and fruit trees, and is dated 1782, when the firm was Brunton and Forbes. Five years later the same firm had become Brunton, Forbes and Hunter, and as such it issued another Catalogue of trees. I have the Trade Card of the firm as it stood in 1787, and also one of the still later metamorphosis when J. A. Hunter was sole partner, and it is the latter which is reproduced as above stated. The shop in Birmingham appears to have always been in High Street, but the number of the house was successively 83, 25 and 18, possibly the same house with a reshuffling of the numbers. *W. Roberts, 18, King's Avenue, Clapham Park, S.W.*

American Blight (see pp. 50, 77, 92).—That the American Blight is not merely a wound parasite, but is the cause of wounds in which it afterwards resides, I proved as long ago as the summer of 1888, about August. This is corroborated by Mr. Bartlett (p. 50) and *Market Grower* (p. 77). At the time to which I refer I found American Blight on the young shoots of an Apple tree at Chiswick, with cracks in the wood and bark more than 1 inch long. I made sections of the shoot and found the wood distorted and swollen owing to a great development of the parenchymatous tissue, and concluded this swelling was due to the irritation set up by the punctures of the aphides, and was the immediate cause of the splitting. In the 1900 edition of *Thompson's Gardener's Assistant*, in the chapter on Insect and Other Plant Enemies, I wrote the result of my experience as follows: "The insect lives in colonies in the crevices of the bark and on the roots of Apple trees, from whence it spreads to the young wood in summer, and, sucking the juices with its pointed beak, causes the shoots to split open and to form cankerous-looking wounds, in which it lodges, and increases the injury from year to year." During the present month I have also noticed a copious covering of the white woolly matter on the young shoots of young Apple trees on walls, in a Berkshire garden. *J. F.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

SEPTEMBER 24.—*Present:* Mr. E. A. Bowles, M.A. (in the chair), Sir Everard im Thurn, Messrs. W. Hales, J. W. Odell, E. J. Allard and F. J. Chittenden (hon. sec.).

Primula japonica proliferous.—Mr. Chittenden showed a plant of Primula japonica from Wisley in which the flower scape bore a leaf about 2 inches above its origin and in its axil a well-developed plant, so that the resulting growth appeared almost like a runner from the old plant.

Aberrant Maize.—Mr. H. Cowley sent a portion of a staminate inflorescence of Maize the main branch of which bore at its apex several pistillate flowers in a group.

Helenium autumnale.—Mr. Wood, of Ashtead, sent inflorescences of Helenium autumnale virescent and with numerous lateral proliferations which usually accompany virescence in this plant. Similar growths have been figured in the Society's *Journal*.

WINDSOR, ETON, AND DISTRICT HORTICULTURAL.

SEPTEMBER 28.—The second annual show of the Windsor, Eton, and District Horticultural Society, for the encouragement of increased food production at Windsor, Clewer, Old Windsor, Eton Wick, and Datchet, was held on Saturday, the 28th ult., at the Royal Albert Institute, and the exhibition proved entirely successful.

The championship of the show was gained by Mr. A. COOMBS, of 20, Bexley Street, Windsor, for an excellent collection of six vegetables, including Michaelmas White Cauliflower, Royal Favourite Leeks, A1 and Ailsa Craig Onions, Tomatos, Prizewinner Beans, Up-to-Date, Arran Chief, and Factor Potatos. Mr. COOMBS also won the 1st prize in the class for Spring Onions. Another very successful exhibitor was Mr. R. WILSON, of Shaw Farm, who won the 1st prizes for (a) a collection of vegetables (four kinds), and (b) Potatos; 2nd for

Celery, 3rd for Spring Onions, and 3rd for Carrots. Mr G. HAINES, of Old Windsor, was second in the championship class, and he won 1st prizes for Turnips and autumn Cauliflowers, 2nd for Runner Beans, 2nd for the heaviest Marrow, and 3rd for Potatos. Mr. G. SUMNER, of Clewer, Mr. A. G. WEBB, Mr. R. RUSSELL, Mr. A. MINTER and Mr. E. GLASS were other successful exhibitors. In the working gardeners' class Mr R. SAVAGE and Mr. H. T. LAMBERT won the 1st and 2nd prizes respectively with fine produce.

A feature of the show was an exhibit of Apples staged by Mr. J. C. ALLGROVE, The Nursery, Middle Green, Langley. The varieties included magnificent fruits of Rev. W. Wilks, Cox's Orange Pippin, Peasgood's Nonesuch, Ribston Pippin, Golden Noble, Charles Ross, Worcester Pearmain, and James Grieve.

BRITISH MYCOLOGICAL.

THE British Mycological Society held its twenty-second annual week's fungus foray at Selby from September 2 to 14, under the presidency of the Very Rev. David Paul, LL.D., D.D. The meeting was held in conjunction with the Yorkshire Naturalists' Union, and on Monday evening, September 9, Dr. H. Wager, F.R.S., delivered a popular address on Fungi to a large audience consisting of members of both societies. Excursions were made each day to various woods within easy reach of Selby, and, as usual, the mornings were devoted to the examination of the specimens obtained. Probably on account of the previous dry weather the larger fungi were not so plentiful as the field-mycologist could wish, but a number of interesting species were obtained, including Lepiota Bucknalli, L. castanea, Leptonia incana, Inocybe Godeyi, and I. rhodiola. Records were also made of a number of parasitic fungi causing injury to crops, such as Erysiphe graminis, Puccinia graminis, P. glumarum, P. dispersa, Ustilago Avenae, and Gloeosporium ribis.

On Wednesday, September 11, Dr. Paul delivered his presidential address, "On the Earlier Study of Fungi in Britain," dealing with the earlier mycologists up to the time of Berkeley. Other papers given during the week included two by Dr. H. Wager, on "Spore Colouration in the Fungi" and on "A Fluorescent Colouring Matter from Leptonia incana"; on "Some New or Rare British Parasitic Fungi," by A. D. Cotton; and "Observations on Some Sandflats Fungi," by H. J. Whitlow.

At the annual general meeting of the society, held on Tuesday, September 10, the following officers were elected for the year 1919: President, Dr. H. Wager, F.R.S.; vice-president, Miss G. Lister; general secretary and editor, Mr. Carleton Rea, B.C.L., M.A.; treasurer and foray secretary, Mr. A. A. Pearson; secretary and recorder, Miss E. M. Wakefield. The council for the government of the society consists of the above officers, *ex officio*, together with the following elected members: Mr. W. N. Cheesman, J.P., Dr. J. S. Bayliss Elliot, Professor M. C. Potter, M.A., Sc.D., and Miss A. Lorrain Smith.

IVERK AGRICULTURAL.

SEPTEMBER 19.—A fruit show was held in connection with the annual exhibition of the above society in Bessborough Park, Piltown, Co. Kilkenny, on Thursday, the 19th ult.

Winners of the medals presented by the Countess of Bessborough in the open class for collection of Apples, 6 cooking and 6 dessert sorts, were: 1st, Lady EVA WYNDHAM QUIN; 2nd, Lady IRENE CONGREVE; 3rd, A. G. BOWERS, Esq., J.P.

The principal winners in the single-dish classes (farmers only) were Messrs. A. G. BOWERS, E. DRUMMY, Ballinc; RICHARD DALTON, Jamestown; JOHN ASHWORTH, Piltown; Mrs. EGERTON, Piltown; and Mrs. BEETLE.

Among the outstanding exhibits were a magnificent dish of Apple Annie Elizabeth in Lady CONGREVE'S collection; a grand dish of Bramley's Seedling shown by Mrs. BEETLE in a very strong class for this variety; excellent fruits of James Grieve shown by Mr. N. Tyson and American Mother shown by Mr. A. J. BOWERS. A fine non-competitive exhibit was staged by the Earl of BESSBOROUGH, K.G. A collection of bottled fruits and vegetables was arranged as a centre-piece, and suitably and effectively arranged around it were dishes of cooking and dessert Apples, dishes of Peaches, Plums, Gages, Figs, Grapes, ornamental Crabs, and Tomatos. The exhibit also included various vegetables.

A collection on behalf of the War Horticultural Relief Fund, organised by the Countess of Bessborough, realised the sum of £11 6s.

CROPS AND STOCK ON THE HOME FARM.

LIFTING POTATOS.

NOTHING is gained by leaving Potatos in the ground after this date, especially if there is any suspicion of disease in the tubers. No method is so effective as digging them with steel forks, but where quantities are grown this plan involves too much labour and expense.

I use a Powell Digger, which has a stout iron share that cuts under the tubers and loosens the soil; following this is a set of forks closely arranged, which work in a rotary manner, throwing outward at right angles, the soil and

FIG. 54.—POTATO CROPPING ON THE CRICKET GROUND AT SWANMORE PARK, BISHOP'S WALTHAM.

Potatos. One operator, the two. A square not some 3 feet wide is arranged on a frame, which prevents the tubers going too far, thus making it easier to collect them. The digger is drawn by two horses, a seat attached to a centre pole similar to a grass cutter. The horses take the outside row and return the opposite way, taking the field in convenient blocks of an acre or more. Many pickers are required to keep the digger employed as the tubers are thrown out at last as the horses can walk. Women and boys can do this work quite easily. To expedite the work the pickers collect all the tubers, irrespective of size, into baskets or sacks, and a second collects them. Grading can be done with a machine later on, thus providing employment during wet weather if such is available.

Sometimes too long haulm may inconvenience the digger somewhat, but to obviate this the tops may be cut to the ground level with the grass cutter and then collected and removed or burnt on the ground. Should the share on the digger not be low enough to loosen all the tubers (and I find this season they are deeper set than usual), Planet Grubber should follow the machine.

As a matter of general interest I may state that the estate cricket ground at Swanmore Park was ploughed up and planted with Potatos this year, and the accompanying illustration (fig. 54) shows the crop of Iron Duke when in full leafage.

CABBAGE FOR COWS.

Although grass is abundant, especially where the pastures were dressed in the autumn with basic slag or farmyard manure, it does not now contain so much "proof" as in the month of August, owing to the continuous rains of the last few weeks and an absence of sun. Naturally the milk is not up to the usual standard of quality, and the difference is quickly evident in the quantity of butter produced. Where a contract exists for weekly supplies of butter steps should be taken to make up this deficiency in the quality of the milk. As it is not possible to obtain concentrated cake in quantity, and if it were this is too costly to be liberally employed, Cabbages of the Drumhead type are a good substitute. Cabbages from seed sown in April and planted out early have done remarkably well this season.

Heavy, solid heads are now available, and these, given to the cows in small quantities, night and morning, after milking, either in or out of the cow house, will improve the quality of the milk very considerably, especially if a small amount of good meadow hay can be given during the milking period. Care should be taken to give the Cabbages sparingly at first for fear of tainting the milk until the animals have become used to the change of food.

TESTING MILK.

No matter what breed of cows is kept for milk production, it is a good plan to have the milk from individual cows tested for its butter-fat quality. Milk for sale must contain at least 3 per cent. of butter fat, a minimum which some cowkeepers say is too high a percentage to maintain in a natural way without incurring heavy expenses for artificial food. I do not agree that this standard is too high, and I also think the public should be protected. The remedies for the cowkeeper are three: Feed better; improve the quality of the animals; or add a Jersey or Guernsey animal to the herd, be they shorthorn or cross-bred cows. One cow of the kind noted will make all the difference to the bulk quality of the milk, especially if the natural butter-fat percentage in her milk reaches 6 per cent. The periodical testing of milk may prove that a cow is temporarily unwell, or a cow may prove to give habitually low results, and such an animal should be got rid of, as no more cost is incurred in keeping a good animal than an inferior one.

The testing of milk has brought to light many surprising results. I have known Jersey cows that were looked upon as models of quality give

a butter-fat percentage of 2.5 only, while in others it is common to obtain as much as 5 per cent. to 6 per cent., therefore it will be seen that the testing of milk is an advantage to the cowkeeper, even if he has but one animal.

The Gerber tester is an instrument that can be used at home, but possibly it is too expensive for a small herd. Another method is to send ½ pint of milk, tightly sealed in a *filled* bottle, to the County Council Dairy School, where the test will generally be made for 1s. per sample. The object in *filling* the bottle is to prevent the formation of butter, which would take place if there was a space left owing to the shaking of the milk during transit. *E. Molyneux, Swanmore Farm.*

Obituary.

Frank Harris.—We learn with regret of the death of Mr. Frank Harris, Superintendent of the Stockport Parks. Mr. Harris was formerly gardener to Lady Henry Somerset at Eastnor Castle, but for the past 18 years he had charge of the parks at Stockport. He was 58 years of age, and leaves a widow, but no children. At the interment, which took place at Mottram Church on Wednesday, the 25th ult., many well-known horticulturists were present, also members and officials of the Stockport Corporation.

Dr. B. D. Halstead.—The recent death of Dr. Byron D. Halstead removed an interesting personality from the botanical circles of the United States. He graduated at Michigan Agricultural College, and subsequently occupied the Chair of Botany at Ames College.

TRADE NOTES.

BRITISH FLORISTS' FEDERATION.

At the recent Committee meeting of the British Florists' Federation twenty-three new members were elected, and the suggested Sundriesmen's Sub-Committee was heartily approved. This sub-committee is already busily at work on matters affecting the manure trade. The returns showing how flower-growers have increased food production, both out-of doors and under glass, were considered satisfactory. The position of bulb growers, and the question of fuel for glass-houses, were considered at length, and considerable progress was reported in the preparation of the Market Credit Index.

MR. THOS. ROCHFORD.

The death of Mr. Thos. Rochford, of Turnford Hall Nurseries, Broxbourne, removes a prominent member of the flower trade from Covent Garden Market. As the eldest son of the late Mr. Thos. Rochford, he was largely responsible for the conduct of the business of Thos. Rochford and Sons, Ltd. For some time past he had been in failing health, and no doubt the added responsibility caused by the absence of some of his brothers, who are in the Army, hastened his death, which occurred on Friday, September 27: the funeral took place at Cheshunt on October 1. A magnificent floral tribute of affection and regard was sent by members of the staff at Broxbourne and Covent Garden.

LAW NOTE.

A TENANCY DISPUTE.

An interesting point affecting tenancy was raised at the Lancaster Police Court, when Mr. T. P. Tilly, on behalf of Miss Leeming, of Greaves House, applied for an ejectment order against Joseph Weatherill, gardener, who had occupied the lodge at Greaves House. Mr. Tilly said it was not obligatory on the defendant to occupy the lodge, but he elected to do so. If he had not done so he would have been given wages in lieu of rent. Miss Leeming, in reply to Mr. W. H. Winder, who defended, denied that it was only after the defendant got military calling-up notice and was given a month to get work of national importance (other than looking after Vines and Peaches), that she decided to dismiss the defendant. She was dissatisfied in June and meant to dismiss him, but was away in Scotland. Mr. Winder produced the advertisement relating to Weatherill's appointment, which stipulated "Cottage free," and said if occupation was by virtue of office or service for the more convenient performance of his duties, the Court had no jurisdiction. Mr. Tilly mentioned cases where it was held that occupation rent free as part remuneration was a tenancy, and not a service occupation. The Bench held that they had no jurisdiction.

ANSWERS TO CORRESPONDENTS.

Celery Leaf Spot: *W. F.* The spots are due to the presence of Septoria Petroselinii var. Apii, a fungous disease that has proved very troublesome in recent years. It is hardly possible to effect a cure at this stage, and we doubt whether anything can be done to check the disease now. Another year spray the young plants at intervals from the seedling stage onwards with weak Bordeaux mixture or a solution of potassium sulphide.

Correction: Mrs. Jenner, Wenvoe Castle, near Cardiff, was the winner of the 1st prize in the class for 6 varieties of Onions at the R.H.S. vegetable show on September 24, not Mr. Jones, as stated by our reporter. The gardener, Mr. Wheeler, informs us that the points obtained in this class assisted him in winning the R.H.S. Challenge Cup offered to the exhibitor obtaining the most points in the show.

Cyaniding Vineries and Fruit Houses: *G. N.* Wait until the Vines and fruit trees are dormant, and there are no decorative plants in the houses. For every 1,000 cubic feet use 2½ ounces of sodium cyanide, 5 fluid ounces of sulphuric acid, and 15 ounces of water. Cyanide the houses on two occasions, with an interval of 24 hours. Allow a 50 minutes exposure on each occasion, and arrange for a temperature of 50° to 55°. With reference to the other matter, we advise you to write to Messrs. Strawsons, 71a, Victoria Street, London; and Messrs. W. Wood and Sons, Wood Green, London, N.

Galls on Apple Shoots: *J. W.* The gall-like growths are caused by the larvae of the Pith Moth. These larvae are hatched in late summer, feed for a time on the leaves, and then bore into a bud. Later they get under the rind of a spur or shoot, and remain there for the winter. In spring they tunnel along the spur or shoot, causing the leaves and bloom to wither and die. There is no remedy beyond cutting off flagging spurs or shoots in spring and burning them. This destroys the larvae and prevents them from developing into moths. Any affected wood that may be detected during winter pruning should also be cut off.

Grape Spot: *A. L.* To prevent the spread of Anthracnose, or Grape Spot, disease, caused by Gloeosporium ampelophagum, dust the leaves and shoots with flowers of sulphur mixed with a little quicklime. If the disease persists, give a second application ten days after the first and add more quicklime to the sulphur. If necessary give further applications at intervals of ten days, increasing the amount of quicklime until it is in almost, but not quite, the same proportion as the flowers of sulphur. Washing the rods during winter, while quite dormant, with a solution of sulphate of iron is considered to be a good preventive measure.

Names of Fruits: *E. J. C.* All the specimens represent Cox's Orange Pippin.—*W. P. D.* 1, Warner's King; 2, Gascoyne's Scarlet; 3, not recognised; 4, Golden Noble; 5, Allington Pippin; 6, Bismarck; 7, The Queen; 8, Bramley's Seedling; 9, Winter Greening; 10, probably Mère de Ménage; 11, King of the Pippins; 12, Dumelow's Seedling.—*W. E. A.* Pitmaston Duchess.—*P. and Co.* Red Apple, Cellini; russetty Apple, Ribston Pippin.—*R. E. J.* 1, Fearn's Pippin; 2, Cox's Orange Pippin; 3, Bramley's Seedling; 4, not recognised; 5, Lemon Pippin; 6, Dumelow's Seedling.—*S. S.* Smart's Prince Arthur.—*G. W. M.*—1, Durondeau; 2, Pitmaston Duchess.

Names of Plants: *H. E. B.* 1, Euonymus europaeus; 2, Commelina deficiens.—*J. H.* 1, Nerine Fothergillii major; 2, Pieris floribunda; 3, Gaultheria Shallon.—*L. S. A.* 1, Chrysanthemum uliginosum; 2, Aster var. (Michaelmas Daisy), not in flower; 3, Crataegus punctata var. xanthocarpa; 4, C. coccinea.—*R. Hines.* 1, Hieracium aurantiacum; 2, Phygelius capensis; 3, Potentilla fruticosa; 4, Sisyrinchium striatum; 5, Tradescantia virginiana; 6, Salvia farinosa; 7, Isoloma hirsuta; 8, Liriope spicata; 9, Selaginella Braunii.—*A. T. H.* Acanthopanax aculeatum.

Scab on Apple Leaves: *P. P.* The trouble has nothing to do with the winter spraying of the trees with caustic alkali wash nor with the spraying of the Potatos under the trees. It is caused by the fungous disease Apple scab (Venturia inaequalis). You are no doubt familiar with scab on the fruit. This is the same disease on the leaves. When pruning in winter you may find the disease also on the young shoots, causing the bark to rupture or have a pimply appearance. If so, cut these shoots off and burn them. Use lime-sulphur wash for winter spraying this year, and apply the same wash, but mixed according to the maker's directions, for summer spraying, as soon as the bloom has fallen, and again about a fortnight later.

Sugar from Sugar Beet: *J. T. W.* Full particulars of the method of cultivating Sugar Beet and of making syrup from the roots were given in the *Gard. Chron.* of May 18, p. 210. The Food Production Department has issued a leaflet dealing with these subjects, and copies for distribution among local growers may be obtained on application to the Department, 72, Victoria Street, Westminster, S.W.

Transplanting Large Yew Trees: *T. W. B.* Given the proper appliances and requisite care, there should be no difficulty in safely moving and transplanting a large Irish Yew tree 150 years old and 20 feet high. There are numerous instances of similar removals on record, notably by the Messrs. Barron, of Barrowash, and Messrs. J. Cheal and Sons, Crawley. The late Mr. Wm. Barron transplanted many large trees, and a notable feat was the successful removal and transplantation of the famous Buckland Yew, near Dover. The work was done in 1880, when the tree was of huge size and over a thousand years old. The Buckland Yew is referred to in Doomsday Book.

Unhealthy Roses: *H. E.* The evidence is insufficient, but we feel sure the amount of magnesia in the soil is not responsible for the failure. So far as we are able to judge both soil and position are far too dry and hot for Roses, and the importation of heavier soil, with the addition of farmyard manure, would result in substantial improvement.

Winter Rations for Cows: *C. C.* For Jersey cows the winter rations should start at the end of October or early in November, when the cows "lie in." Give 2 lbs. of Bibby's Dairy Cakelettes at the morning feed and the same quantity in the afternoon, just previous to milking, 6 lbs. of long meadow hay in the morning and 10 lbs. in the afternoon, half at milking time and half about 7 o'clock; Mangold, sliced into pieces an inch wide and 4 inches long, but not pulped smaller, 15 lbs. in the morning and the same quantity in the afternoon. Mix 5 lbs. of Cabbage with the Mangolds, both morning and evening. The feed of Mangold and Cabbage should be given after milking, as the milk may have a slightly unpleasant flavour if it is given just previously. Some dairymen consider Mangolds should not be fed to cows until February, as they are injurious until their sugar content is fully developed, and Turnips and Swedes given instead. Where milk is the only aim, there may be little harm in their use, but if butter is made Mangolds are not advisable, as their flavour has a much longer period in which to develop while the cream is ripening.

MESEMBRYANTHEMUM SIMULANS

MOST persons [illegible] aware that [illegible] some open in the morning [illegible] evening only, and [illegible] in bright sunshine remaining [illegible] times. I am tempted to [illegible] know which it is the [illegible] noted at about their fullest [illegible] time of writing I have two plants of Mesembryanthemum simulans in flower and each accurate time keepers in the matter of opening and closing their flowers that there seems to be something positively uncanny about it. As this species is interesting [illegible] following account may perhaps indicate someone in South Africa to make observations and record if it behaves in the same manner in its native country.

Mesembryanthemum simulans was discovered by Dr. R. Marloth at Kuipdraai [illegible] grows in the region of Aberdeen Road railway station in South Africa. The name simulans (imitating) was given to it on account of the manner in which the leaves by their colour and texture bear a close resemblance to the stones among which it was found growing. Under cultivation the leaves become greener and less grey, so that much of that resemblance is lost. According to Dr. Marloth the plants are becoming exterminated by goats, who "search for them during the dry season." The two plants of M. simulans that I possess were kindly sent to me by Dr. Marloth, and both are in flower as I write. Under natural conditions so many as four flowers are sometimes produced upon a plant in one season, but, under cultivation here, probably one or two flowers is all that can be expected, owing to want of sunlight during the flowering season. The first flower I had opened in the afternoon of August 28, and I found that at 7 p.m. it had closed. Since that date I have watched it closely, and every day for nine successive days it commenced to expand at 3.30 p.m. and closed again at 6.30 p.m., taking nearly an hour to expand fully and about the same time to close. On September 2 a flower on another plant, being ready to open, commenced and finished its operations at about the same hours, but was about ten minutes later than the first flower in starting to open, closed about ten minutes earlier, and behaved in this manner day after day. With the expansion of the petals the flower gives forth a strong and pleasant odour resembling that of Cocoanut. When the flowers first opened they were respectively 1¾ and 1¾ inch in diameter, but the petals increased in length daily, so that finally the flowers were 2¾ and 3 inches in diameter, with the centre a bright yellow, [illegible] petals, [illegible] series, [illegible] Lily of the Valley, [illegible] petals [illegible] first 4·5 days, although gradually [illegible] after the [illegible] petals [illegible] flower [illegible] afterwards the stigmas separate from one another and become very [illegible] the [illegible] lens.

FLOWER OF MESEMBRYANTHEMUM SIMULANS. NATURAL SIZE.

The regular opening and closing of the flowers of this species is quite independent of the [illegible] and [illegible] are sure to [illegible] the flowers opened just the same, with the exception of one day when the temperature only rose to 60°, which was not sufficient heat [illegible] expand [illegible] 3.30 as usual, but only expanded very slightly, remained in that state for its usual period, and closed up at 6.30 "as nothing to plum."

The hours I mention are those of actual Greenwich time, not those indicated by "summer time" clocks, for I believe these plant would refuse to be controlled by any Government, they are probably regulated their actions by certain [illegible] according to real time, and will continue to do so to the end, but by what means they keep and respond to the hour is a mystery [illegible] and [illegible] several other species of the more remarkable genus.

Whilst examining a flower of M. simulans it was visited by one of the pollen-eating flies, probably a species of Syrphus, which was so tame that it allowed me to pick up the pot containing the plant and adjust a lens of short focus so that I could watch it feeding, and a most interesting sight I found it to be. The fly settled on the petals with its head over the stamens, eating some of the pollen then, with its two front feet, it took an anther between them and, by a rubbing motion, proceeded to scrape or squeeze some pollen out, for the flower had evidently but once before and had only just begun to shed its pollen that day. This pollen the fly then began to pick up with its proboscis. Everyone who has a microscope is sure to have seen the proboscis of a blow-fly, and to know what a beautiful object it is. This fly had similar lobes to its proboscis as the blow-fly has, and the manner in which it rapidly picked up the pollen, a few grains at a time, was one of the most interesting sights I have ever seen under a lens. These lobes are as handy to the fly as our own fingers are to us, as it continually pibbles in any and every direction, [illegible] transversely, or obliquely. After feeding for a few minutes upon the pollen [illegible] the anther, the fly then [illegible] cleaning its feet, and [illegible] speed of it commenced to [illegible] some grains that were upon [illegible] before swept off the grains [illegible] the petal by folding the lobes [illegible] and [illegible] both surfaces of the [illegible] in the same way as [illegible] and then upon the upper surface of a leaf and the fingers beneath it, and then with a withdrawing motion proceeded to bring away anything that might be upon the surface. Its motions were too rapid for me to see how it got the pollen into the tube or gullet that extends to the proboscis, but on one occasion it seemed to have picked up a pile of [illegible] grains in a heap, which seemed more than it could swallow at once, and it then appeared to me as if it were rubbing the inner surface of one lobe against that of the other, so in some way, so as to separate the grains, which were soon disposed of.

A very complete description of this species has been published in English the following may be useful:—

M. simulans, Marl. Plant stemless. Leaves, [illegible] very spreading, 2·2½ inches long, [illegible] broad, ¾ inch thick, ovate, acute, [illegible] face, keeled on the back, dull [illegible] or grey-green densely covered with dark green dots. Flower central between the bases of the leaves, very shortly pedunculate or subsessile. Calyx of ovate acute keeled bracts [illegible] below the calyx, coloured like the leaves but more glaucous. Calyx 5-6-lobed; lobes 5-6 lines long, 3-5 lines broad, ovate or ovate-lanceolate, subacute or obtuse, the inner with membranous margins, of a somewhat glaucous green with a slight pink or purplish tinge, dotted with dark green. Flower on the first day of opening 1·2½ inches in diameter, day by day enlarging to 2¾ inches in diameter, commencing to expand about 3.30 p.m. and closing at 6.30 p.m., irrespective of sunshine or cloud if the temperature is not below 70° Fahr., lasting about 12 days, having a strong and pleasant odour resembling that of Cocoanut. Petals more than 150, in 4-5 series, free to the base, spreading in different planes, the outer reniform, 9-13 lines long, 1¾ line broad, linear-lanceolate, either entirely bright yellow on the inner surface or with the basal part white, whitish or pale pinkish on the back, scarcely shining; under a lens the petals are seen to have numerous linear cells of a more translucent nature than the other part, which I at first mistook for glands such as are present in the petals of Mesembryanthemum and M. nutabile, but under a compound microscope I find that they are not glandular cells. Stamens very numerous (over 200), forming a dense cluster 7-8 lines in diameter; filaments white; anthers orange-yellow. Style none. Stigmas 10-12, equalling or a little longer than the stamens, filiform, at first erect and closely clustered together, afterwards (when receptive) separating, spreading, and becoming more or less curly at the tips, yellow. Fig. 51 represents the plant half natural size. The photograph was taken at 1.15 p.m. Greenwich time before the flower had fully expanded. It had opened only once previously to being photographed, and on the two days before the photograph was taken it refused to open at all, as the temperature was below 70° Fahr.

N. E. Brown.

CONFESSIONS OF A NOVICE.

It is a long time since I made a confession, and I feel the consequence of my reticence acutely, for it never happened in any of my many confessions of ignorance that they did not bring me wisdom—not, be it said, of their own virtue, but from the rich stores of the experts who answered my questions. But my silence is only a sign of preoccupation with war work, and by no means an indication of faithlessness to my true love of horticulture. Now, when my days are passed, like those of all of us, in either controlling or being controlled, I am able no longer to ask useful questions—that is, those of which the answers solve either my own or other people's difficulties. To be able to ask these questions means to be at work among the plants, and my great misfortune has been that I have had no time for work in the garden. My gardener often sighs with me in a decorous way for the old times when we laboured together, but nevertheless ascribes the fact that the vegetables are better than they used to be to my abstention from what he calls "our trials." They are so good, indeed, that we get very few of them indoors. Since flowers were abandoned for the garden and vegetables took their place and serve for decoration, only rarely may they be spared for use. Thus I arrive at my subject, which is to congratulate H. H. on his enthusiastic championship of vegetables. The Orchids which he was wont to cherish as the apple of his eye are rejected in favour of Onions, and the Rhododendrons give place to his affections to Runner Beans. What's a Poinsettia to a Potato?

But when H. H., more royalist than the king, urges that Kew should descend from its high estate and, like Diocletian in his old age, grow Cabbages, even I, a novice, must cry beware the enthusiasm of the convert. Kew is to me an Imperial possession with great and wide mission. Its fourfold function is, as I imagine, to foster and develop the economic botany of the Empire, to advance floristic knowledge, to train men in the understanding and love of horticulture, and to show novices beautiful things and how to produce them. If it succeed—and I think that it does succeed—Kew deserves our sincere thanks, and not an added burden which others can well bear—that of growing vegetables. So, in so far as a pupil may criticise a master, I would respectfully suggest that though Kew does well to grow Potatos to win the war, the best thing that it can do when war is over is to reconcentrate its powerful energies on its own great tasks, which will be even more important and onerous than in the past.

But to return to subjects more within my competence. I have been remarkably successful in growing, or rather in introducing and getting my gardener to grow, a Canadian dwarf strain of Sweet Corn. It has matured its cobs perfectly, but the trouble is that when mature they are uneatable, and to catch them in the right unripe stage requires lynx-eyed vigilance. This is a drawback to a "vegetable" which otherwise I believe I should come to like in time. I imagine that the knowledgable can judge either by the state of the tassels or by the feel of the cob when the fruit is ready for gathering. In any case this dwarf strain, which can be planted closely, ripens well enough here, and should be grown by all who have, and who has not?—American friends. A. N.

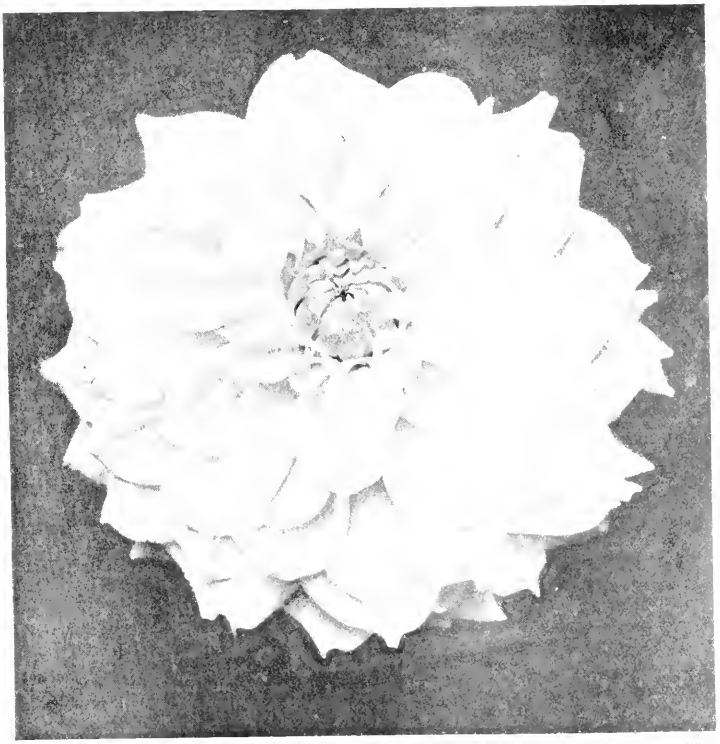

FIG. 55.—DAHLIA MEDUSA: COLOUR PRIMROSE-YELLOW, WITH FAINT SUFFUSION OF PINK AT THE TIPS OF THE FLORETS.

(R.H.S. Award of Merit, N.D.S. First-Class Certificate, Sept. 24, 1918. See p. 175.)

ORCHID NOTES AND GLEANINGS.

LAELIO-CATTLEYA ELIZABETH.

THE first flower of a pretty cross between Laelio-Cattleya Clive (L. pumila praestans × C. Dowiana aurea) and Laelia purpurata Annie Louise, sent by Frederick J. Hanbury, Esq., Brockhurst, East Grinstead, is of special interest, as it demonstrates the fact that fine abnormal colour variations in the parents used may be transmitted to the progeny. The varietal peculiarity in Laelia purpurata Annie Louise, for which the late Mr. Law-Schofield obtained the Royal Horticultural Society's First-class Certificate on May 31, 1899, consisted in the petals (instead of being of an uniform blush-white on pale rosy-lilac) having the greater part of their surface covered with dark rose-purple veining, the lines being merged with a deep magenta-rose tint, only the narrow margins being of the normal colour of the species.

The same characters, in a still brighter tint, appear on the extended lanceolate petals of the new hybrid L. C. Elizabeth, the narrower sepals of which are very light lilac on a white ground. The handsome lip, which has a tubular base indicating L. pumila praestans, is deep maroon-crimson in front, and orange on the centre and base.

POMOLOGY.

PHILOLOGICAL NOTES.

BLOOM.—The origin of this word as given by Johnson, Murray, Skeat, etc., when applied to the delicate powdery deposit on fruits, can hardly be considered satisfactory. For instance, the main suggestion is that it is so called from "a state of greatest beauty or loveliness." In French the word "Fleur" is commonly used, another word being "Pruine," especially for Plums (Littré). Now "Fleur" ordinarily means flower, blossom, or "Bloom," so that we have terms of identical meaning in the two languages, so far as form goes. Littré gives *Bourguign.* Flo, *Picard* flour, *Provenç.* Span., *Portug.* flor, *Ital* fiore, *Latin* florum. Cotgrave (1650) gives the French for bloom, in the present sense, "Fleur, Flour," and the connection between the words becomes obvious when we find that "fleur de farine" means "flower, the finest meale meale dust or mill dust"; or Littré, "Fleur de Farine—la plus belle farine du froment," or Italian, "Fiore di farina"; in other words, bloom on fruit is simply a dusting of fine powder or flour or flower. Seeing that flour and flower are mere variants in spelling the same word, we may take it that insistence on the correctness of "flowers of sulphur" as against "flour of sulphur" fails anyhow, for the spelling should be singular, *i.e.* flower, and at this merely amounts to a sort of super-pedantry.

The varieties of Apples known as "Belle Fleur" deserve a further note. I have an old tree which has been identified by two authorities, and which seems to agree by descriptions, with Brabant Bellefleur. What clinches the diagnosis to my mind is the fact that when well ripened in a good season, and especially during storage, the fruit develops a beautiful "bloom," a feature that is not very common among Apples; this bloom, I venture to think, has given the name "Belle Fleur." Curiously enough, neither Leroy, nor other pomologies that I have consulted, mention the character either for this or for other Belle Fleurs. Can those who have Belle Fleur jaune, etc., in their collections report on the subject?

PRUINE.—"Poussière glaucque cireuse qui couvre certains fruits particulièrement les prunes" (Littré). French writers often describe certain Plums as "pruinée," *i.e.* with bloom. Etymologically Littré gives *Lat.* pruina

= gelée blanche, hoar frost (par assimilation). The German equivalents, Blaue, Reif, Flaum (also = down), and Hauch may be mentioned, and also that the word "mealy"—evidently allied to Fleur or Flour—is applied sometimes to powdered things—for instance, "mealy bug."

THE PERMAINS.—"The Pearmayn, which to France long ere to us was known, Which careful fruiterers now have denizened our own." (1663.) The origin of the word Permain is perhaps not yet adequately worked out. Littré gives "Permaine," name of a variety of Apple in Normandy; etym., *Latin* Permagna, very large. Hogg, *Fruit Manual*, 5th Ed., 1884, p. 169, says: "The term Pearmain, which is now applied to so many varieties of Apples, signifies the Great Pear Apple. In olden times it was variously written Pearemaine or Peare-maine, being the Anglicised equivalent of Pyrus magnus, just as Charlemagne is of Carolus magnus. A Pearmain, therefore, ought to be a long or Pear-shaped Apple." Whether this is an original idea of Hogg, or whether he borrowed it without giving chapter and verse, is not clear, but I am told that such etymology is of an improbable nature, and not in accord with the rules. Further, does a Pear shaped Apple exist? That is the very opposite of the conical shapes which are quite common, in that the narrower part must be at the base or next the stalk end. Another derivation is given by Murray quoting Foerster (1899), from Parmanus, *i.e.*, of Parma; the author may have been obsessed with the German name "Parmäne." This, too, seems hardly likely. The older spellings are more varied than those given by Hogg. Murray gives Parmain, Permayn, Parmeyn, Pearemain and Pet Pear Pair Pare Peer ... many more. It is difficult to visualise what was meant by the older writers. Thus Cotgrave (1650): "Poire Poire, a Peare Apple, a little russet Apple, (as some hold), a 'Peare-maine.'" Mortimer (1707): "The Russet Pearmain partakes both of the Russetting and Pearmain in colour and taste, the one side being generally russet and the other streaked like a Pearmain." Gerarde (*Herbal*, 1633, p. 1459, quoting "Tabernæmontanus" or Jacob Theodor, of Bergzabern, 1520–1590) mentions (5) Platomela sive Pyra aestiva, The Summer Pearemaine and (6) Platorcharia sive Pyra hyemalis, The Winter Pearemaine, but gives no descriptive effort, apart from a suggestion of flat shape.

Knight (*Pomona Herefordiensis*, 1811, Pl. XXIX) figure the Old Pearmain as a medium-sized Apple of an ovoid or elliptical shape, and distinctly without any coned appearance. He quotes Philips as calling it

"The fair Pearmain,
Tempered like comeliest nymph, with red and white."

To the three derivations given above I would add a fourth, the key to which is the two synonyms for the Pear, formerly well known—the Permaine or Warden. Thus (*v.* Murray) we find, 1483 Parmayn *anglice* a Warden: A Parmayntre (a Parment tre) volemus a Wardentre. Cotgrave: "A Warden or Winter peare, Poire de Garde, a peare which may be kept very long." Looking to old French we find the verb "*permer* or *parmaindre*," and later *parmain* from Latin *Permanere* (cf. permanent), which signifies to remain or continue, to have enduring or lasting and durable qualities. Warden, given by Skeat as a large coarse Pear used to baking may have borrowed its size for rhyming reasons from May Trans. of Virgil):—

"Nor must all shoots of peares alike be set
Crustummian, Syrian peares, and Wardens great."

If the similarity in meaning both of Warden and Permain is so great, it is likely that originally when Apples were described as Permains it was neither their size, nor their shape or appearance that led to the name; it was because they were "good keepers." *H. E. Durham.*

HARDY FLOWER BORDER.

THREE UNCOMMON BORDER FLOWERS.

A NARROW border in front of a tropical plant house (No. 1 at Kew is edged with a broad band of Zephyranthes candida in full bloom, its thousands of white, Crocus-like flowers among the dark-green, rush-like leaves being a pleasing contrast to the spokes of Belladonna Lily, which stand on grand array behind it. Nestling close to the wall is Oxalis Bowieana, the largest-flowered and showiest of the South African Wood Sorrels; the blooms are of the brightest pink colour. These three plants are sufficiently hardy to thrive in such a position as that described without any protection in winter, and as they are at their best at this time of year they are eminently suitable for autumn show. The Belladonna Lily is an old favourite, but the Oxalis is known in this country only as a greenhouse plant, while the Zephyranthes has not yet come into its own as a hardy perennial bulb, though it is as easy to cultivate as a Daffodil and is often to be the best of all Crocuses. Moreover, the plant is evergreen, so that it can be used instead of Box as an edging to borders. At Kew it was first planted about 20 years ago, but had a fierce fight, and at one time all but the Box had to be dug up, and ever since the Zephyranthes has flourished there.

ON INCREASED FOOD PRODUCTION.

FASCIATED VEGETABLE MARROW.

A REMARKABLE form of fasciation is a Vegetable Marrow growing on an allotment at Dr. Kennedy Hill's, E. Dulwich, illustrated in fig. 57. It is of the ordinary green climbing or trailing kind, and shows a thin, membranous expansion in the growth of one stem, which is flattened and about ¾ of an inch in width at the base, gradually widening to a maximum measurement of 5 inches, where it is slightly convex and has twelve large leaves in line at right angles to it. The leaves are arranged in lines some distance back from the growing point, with a space of 8 inches between each line, and at the point where the Marrows are attached there were no fewer than eight pistillate flowers, two of which failed to set; another, after setting, turned yellow and dropped off; the fourth is still adhering to the stem, but is yellow and likely to drop, leaving the four fine Marrows as seen in the illustration.

The growing point has turned under the main stem and is forming a ball of twisted and flattened growth enclosing itself in the centre, and no sign of efforts to obtain release is expanding the mass of growth daily.

I may state that this plant is growing on a heap of stable manure, which, perhaps, has something to do with its abnormal growth.

It will be interesting to see if the seed saved from the plant gives seedlings perpetuating the abnormality. *H. G. King.*

POTATO TRIALS AT ST. OSYTH.

A TRIAL of seven varieties of Potatos has been carried out on a piece of waste ground at St. Osyth Priory, which was considered to be too hot to grow any useful crop. We planted 30 sets each of the following varieties on April 5: Arran Chief, Factor, Great Scot, British Queen, Dalhousie, Scottish Farmer, Eclipse, What's Wanted, and Pink Blossom. This is the second year that What's Wanted has been grown at the Priory and the fourth year we have had Pink Blossom. The results from the trial of 30 sets, planted each 2 feet 6 inches between each row and 15 inches between the sets, all unsprouted sets, 1½ oz. in weight, are as follow:

	Thirty sets.	Per acre.		
	Lbs.	Tons.	cwts.	lbs.
Arran Chief	104	21	11	7
Factor	105	21	6	105
Dalhousie	84	17	3	55
Scottish Farmer	100	20	14	54
Great Scot	122½	25	7	75
British Queen	95½	18	12	30
Eclipse	105	21	15	20
What's Wanted	36	7	9	80
Pink Blossom	49	10	5	51½

Last year What's Wanted yielded at the rate of 13 tons 11 cwts. per acre. This trial seems to prove that What's Wanted requires a good, heavy soil, and that the seed tubers require to be well sprouted before planting. I received four tubers of Conqueror and four tubers of a new variety called Conquering Hero from Mr. Dewar, Dankeith, Kilmarnock, Ayrshire, and cut each

FIG. 56.—CELERY GROWN BETWEEN ROWS OF RUNNER BEANS. (See p. 144.)

Potato into seven 1½ oz. sets and planted them with the others, with the following results :—

	Seven sets.	Per acre.		
	lbs	Tons.	cwts.	lbs.
Conquest	30½	27	1	85
Conquering Hero	39	34	12	85

Conquering Hero is a new white, oval-shaped variety, with shallow eyes, and of first-class cooking quality. The lifting and weighing were supervised by Mr. Willmott, schoolmaster, St. Osyth. *P. M.*

INTERCROPPING CELERY BETWEEN ROWS OF RUNNER BEANS.

At Aldenham we have, for some years past, grown Celery between rows of Runner Beans. Three and four rows of Celery are grown on the flat, in well-prepared ground, and blanching is done by means of brown-paper bands. Very fine produce is obtained in this way, the partial shade from the Beans suiting the Celery admirably. The cost of perfecting the crop is much less, and the crop itself more satisfactory for early supplies than when the plants are earthed up with soil in the usual way. Moreover, the roots of the Celery can be kept well supplied with water during times of drought. *Edwin Beckett, Aldenham House Gardens, Elstree.*

SILVER-LEAF DISEASE.

The widely-spread Silver-leaf disease of Plums, Cherries and kindred fruits promises to become an urgent problem for fruit-growers in the near future.

I have only noted Silver-leaf disease affecting grafted trees, and have never seen the complaint on trees upon their own roots. The two points are very closely connected.

Has the stock upon which the trees are grafted any influence in the matter, and has the operation itself any bearing upon the transmission of the malady?

Several cases of Silver-leaf have come to my notice, especially among Plums and Cherries. A large, trained Morello Cherry was lifted and examined carefully. The first thing noticed was a bad union of stock and graft, leaving an open wound, which the tree had apparently endeavoured to heal from time to time, but failed to do so. This wound led to the core of the tree, and doubtless impeded the flow of sap upward, and it also allowed moisture from the stem and surrounding soil to enter the heart-wood.

Sections of the stem showed that the decayed portion of the wood was greatest just above and just below where the moisture entered, but the decay had spread up the tree, not only in the main stem, but also into the branches, though lessening in diameter in its upward course.

At 6 inches above the point of union the decayed surface occupied two-thirds of the section cut through, and the decay had also travelled downward, but not in quite so rapid a manner.

Whether injury to the tree caused by an old wound, with its consequent check to the sap-flow, and the entry of outside moisture when the tree is in a dormant state are sufficient to cause the disease I hesitate to say. No organism was to be observed which might contribute to the trouble, but in any case the injury and wood decay would soon produce an injurious effect.

The actual disease shows in the silvered foliage, in partially developed fruits, in a reduction of healthy growth, and, finally, in the death of individual branches and the whole tree.

It is possible that injury and results of injuries may contribute directly to the disease, and external injury certainly would aid the disease to enter the tree, if the complaint is due to fungous or other organisms.

All trees should be very carefully planted, and care should be taken to prevent injuring them, and especially the main stems, at any time after planting.

Heavy land should be well drained before planting stone fruits, and a sufficiency of lime rubble or chalk incorporated with the soil.

A trial should be made wherever possible as to the possible immunity of trees on their own roots by planting seedling Plums and Cherries in soil and positions from which trees affected with Silver-leaf have been removed. *P. S. Hayward*

In a recently-issued leaflet the Food Production Department draws attention to the increasing seriousness of Silver-leaf disease in fruit trees. In some localities it has become almost a scourge, and some of the most valuable varieties of Plums, especially Victoria, are threatened with extinction unless drastic measures are taken to check its extension. The disease occurs also in Apples, but less frequently.

In view of the urgent need of combating Silver-leaf, the Food Production Department strongly urges fruit growers throughout the country, especially in the important Plum growing districts, to take energetic measures to destroy all trees which have begun to die back, and to cut out the silvered branches of trees otherwise healthy. It is worth some sacrifice to take this in hand at once, for the fungus fructifies chiefly in autumn, and the longer dead wood bearing the fungus is allowed to remain the greater is the risk of infection. If this work cannot be completed before the leaves fall, all silvered branches and trees which are dying back should be conspicuously marked at once, so that they may be removed so soon as opportunity permits.

In carrying out these operations the following points must be borne in mind :—

(1) The invisible threads of the fungus are often to be found in the tissues of the wood considerably further down the branch than the level at which the silvered leaves appear. Affected branches should be cut back to a point where no brown stain in the wood can be found.

(2) All wounds made by severing branches should be pared over and covered with Stockholm tar.

(3) Dead or dying trees should be completely grubbed up. Exposed stumps on which the fungus can fructify should not be left in the ground.

(4) Severed branches and trees that have been grubbed up should be removed from the plantation immediately, and used for firewood. Small branches should be burnt on the spot. If it is necessary to keep the firewood for any time, it should be stored as far away as possible from fruit trees, and preferably in a shed. To cut down dead trees without subsequently removing them, is utterly useless; and to keep a wood-pile in or near a fruit garden is a practice that cannot be too strongly condemned.

Photograph by H. G. Kent.

FIG. 57.—VEGETABLE MARROW WITH FOUR FINE FRUITS.
(See p. 145.)

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Late Potatos.—The time has arrived when frosts may be expected, and all Potatos should be dug up and harvested. Lift the tubers early in the day to allow them to become dry before gathering them for storing. Seed tubers for planting next season should be carefully selected and stored in a cool, dry place secure from frosts. Reject all diseased tubers, making a careful examination for the purpose, and keep the good ones stored in as dark a place as possible to preserve their flavour, but not so dry as to cause shrinking. This is best achieved by placing them in small heaps in a dry situation and covering them with straw and earth. Arrange them in a ridge about 3½ feet high on a good covering of straw; draw the straw straight over the tubers and cover the whole with soil to the depth of 9 inches. Make the sides of the clamp firm with the back of a spade. A handful of straw may be left protruding at intervals of 4 feet along the top of the ridge to permit of ventilation. Do not open the heap in frosty weather.

Onions.—The recent wet weather has delayed the harvesting of Onions. Any bulbs still out-of-doors should be removed at once to a cold house or open shed where they may be kept dry, and stored later in a proper manner as recommended in the calendar for September 6. Run the hoe through the rows of Onions sown last month to encourage growth before winter sets in, and give frequent dustings of soot and lime.

Winter Spinach.—It is not too late to transplant and make good any gaps in the rows of Winter Spinach. The seedlings should be carefully lifted out of the ground and dibbled in where required, taking care to make the soil firm about the roots. Thin out plants that are crowded, leaving them 6 to 9 inches apart according to the variety and the earliness of sowing; dust the plants lightly with soot as a deterrent to slugs.

General Remarks.—Early Giant and Autumn Giant Cauliflowers need constant attention to prevent waste at this season. Those that are ready for use may be pulled up and hung head downward in a cool shed, or the curds may be protected by bending some of the larger leaves over them. French Beans should be kept closely gathered until frost appears; the pods will keep in good condition for some time if gathered dry. Turnips which have completed their growth should be lifted and stored. Gather all decaying leaves from green crops and use the hoe amongst all late-growing crops while the weather is favourable. Make small sowings every week or ten days of Mustard and Cress. Complete the planting of Spring Cabbages and make good all blanks in the rows. Dust the plants freely with soot and lime until they are well established; this precaution is very necessary where slugs are troublesome.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Climbing Plants.—Plants growing close to the roofs of the conservatory or greenhouse need a thorough overhauling at this time of year. Bougainvilleas may be cut hard back after flowering. Such plants as Cobaea, Passiflora, and Tacsonia may be very severely thinned, thus admitting more light to plants growing beneath them. After this work is finished the glass should be washed both inside and out, and all temporary shading removed.

Watering and Syringing.—The work of affording water to plants growing in glasshouses must be done with much greater care and consideration as the winter advances. I have already mentioned in recent calendars that with the enforced lowering of all temperatures in plant houses during the coming winter, there must be a corresponding reduction of atmospheric moisture. During times of dull, cold

weather keep the houses comparatively dry, and the roots of plants on the dry side. Ventilating the houses must receive careful attention. Whenever the weather conditions permit, admit air freely, for it is only in this way that the atmosphere can be kept dry.

Begonia Gloire de Lorraine.—Plants of this Begonia should be grown in a light, airy house as near to the roof-glass as practicable. It is a mistaken notion that this plant requires much warmth to grow it successfully, for an excess of fire-heat causes weak stems, resulting in a straggling habit of growth. A temperature of 45° or 50° is suitable, and if the house is ventilated judiciously good flowering specimens may be had by this treatment. Some of the plants may now be allowed to develop their flowers, leaving the rest to flower later. Water the roots with extra care, and use stimulants more liberally than hitherto. Keep the atmosphere dry, and especially in the afternoons.

Humea elegans.—For the next two months Humeas need very careful treatment, or many of the plants will die. Do not afford water to the roots until they are absolutely in need of moisture, then rather thoroughly. Grow the plants in a cool pit and place them near the roof-glass. Any coaxing for sooty may be done now. Use a mixture of loam, leaf-mould, sand and crushed brick rubble. Plants to flower in pots may be shifted into 6-inch pots.

Canna. Give less water to the roots of Canna than hitherto to cause the foliage to ripen. The plants may then be placed in such a position as to receive the full rays of the sun, and will thus ripen their growths more thoroughly. Those plants may then be placed in such quarters, such as a cool, frost-proof shed. They should not be placed near to the hot water pipes or the roots will shrivel.

Eucharis.—The forcing of Eucharis should be deferred until the turn of the year, as the plants require much fire-heat to bring them into flower. They may be wintered in a temperature of about 45°. Water the roots sparingly and keep the atmosphere dry. If the plants are infested with mealy bug sponge the leaves with an insecticide.

THE ORCHID HOUSES.

By J. Collier, Gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate.

Temperatures. Sudden changes of temperature must be carefully guarded against, and the fires must be kept clear and regular. Cold draughts must be carefully avoided, but it is necessary that a little fresh air should be admitted daily, if only for a few minutes, in order to change the atmosphere. Avoid a close, stuffy condition of the atmosphere, but which is most harmful to the plants, and insect pests will increase rapidly in hot, dry conditions. It is advisable in every department to open a ventilator on the warm side with the night temperatures, as a sudden fall of several degrees, especially if the atmosphere is unduly moist, may prove very harmful to tender exotics. The following table of temperatures should be adhered to as nearly as possible for the present: East Indian or warmest house, night about 70°; Cattleya house, about 60°; and the Mexican house a few degrees lower. The Odontoglossum house about 55° to 57° at night and about 52° to 54° in the morning. When banking up the fires at night manipulate the dampers so that there may be a slight fall in the temperature in each division by the early morning.

Laelia. Laelia pumila and its many varieties which have been growing in a cool house during the summer will now be benefited by removal to a house having an intermediate temperature. Suspend the plants from the roof-rafters, where the extra amount of sunlight will assist the flowers to open, and favour the development of the new growth. The roots should be well supplied with water until the new pseudo-bulbs are completed, after which less water should be given, but care must be taken that the roots are never allowed to become quite dry. The plants are frequently attacked by white scale insects, which should be diligently sought for, as the pest multiplies rapidly. Plants of Laelia harpophylla starting into growth should be placed in the intermediate house. Water should be given with moderation until the new shoots are well advanced when the plants may be plentifully supplied with moisture. On the completion of the growths less water should be given, or the new pseudo-bulbs may become black, and decay. Dwarf-growing Laelia monophylla is at rest and should be afforded just enough water at the roots to prevent the pseudo-bulbs from shrivelling. Grow the plants in a cool, shady position in the intermediate house. Laelia crispa, L. albida, L. autumnalis and L. Marriottiana are seldom in flower quite, and will need plenty of moisture at the roots.

Lycaste. Plants of Lycaste Skinneri and its variety alba, L. Mary Gratrix, L. Balbisii and L. lanipetala will soon be finishing their young growths and forming a quantity of fresh roots. They will require a liberal amount of water until the new pseudo-bulbs are fully developed; it is important that the compost should at all times become moist, but not cold and sour. The plants will thrive in an airy position in the warmest part of the Odontoglossum house.

FRUITS UNDER GLASS.

By W. J. Geest, Gardener to Mrs. Dempster, Wycliffe, Newcastle, Staffordshire.

Figs. Early Figs trees should by now be [illegible] crop of fruit. Unless the [illegible] fruits that are on, but at this [illegible] advisable to employ fire-heat [illegible] fruit-ripening. Trees [illegible] to be watered [illegible] needed. Do not [illegible] to prevent [illegible] very severe [illegible] of cold nights, as it does us [illegible] more harm than [illegible] necessary to [illegible] the fruit. Security against [illegible] from the [illegible] Scrupulously [illegible] the walls and [illegible] to wash every [illegible] the trees with soap and water [illegible] the [illegible] and [illegible] the [illegible] Figs [illegible] to [illegible] the [illegible] [illegible] [illegible]

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER, *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, OCTOBER 14—
United Hort. B. & P. Soc. Com. meet

TUESDAY, OCTOBER 15—
Brighton, Hove, and Sussex Hort. and Food Production Soc. Fruit and Vegetable Exhibition at Royal Aquarium, Brighton (four days). Croydon Hort. Mut. Imp. Soc. meet. Southampton Roy. Hort. Soc. Autumn (Food Production) Show (two days).

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 49.7°.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, October 9, 10 a.m.: Bar. 30.1, temp. 51, Weather Raining.

Studies in Cereal-Breeding.

The paramount importance of increasing the yield of our cereal crops at the present time adds to the intrinsic interest of the following account of recent research in the breeding of cereals contributed by Prof. Punnett, whose own researches in the breeding of plants and animals have contributed so signally to the advancement of our knowledge of this subject:—Careful work on the breeding of the standard cereals is always worthy of the attention of the scientific agriculturist. However trivial the characters investigated may appear at first sight, they are almost certain to have some bearing upon problems of high economic importance. The more we know about the genetics of every character of these invaluable plants, the better is our position for getting out of them the best that they can give.

The results of some breeding experiments with Oats and Wheat, conducted by Mr. A. St. C. Caporn during the past few years on the University Farm at Cambridge, are published in the last number of the *Journal of Genetics*.* In one paper he gives an account of the results of crosses made between certain varieties of Oats with tight paleae, such as Thousand Dollar, and Avena nuda, with loose membranous paleae. Oats with tight paleae never have more than four grains to the spikelet, while Avena nuda gives up to as many as 10. But Avena nuda, with its membranous paleae, has the disadvantage of easily shedding its grain on ripening. An Oat combining the many-grained spikelet and the tight paleae would be of pre-eminent agricultural value. Occasionally seedsmen have put on the market a variety extracted from a cross with Avena nuda in which it was claimed that the rather higher yield was due to this combination. Mr. Caporn's work, however, does not support this contention. His careful analysis shows that there is some incompatibility between tight paleae and the many-grained spikelet, and he is inclined to conclude that when membranous paleae are replaced by thick, stiff husks, the extra growth which would have produced the additional grains is used up instead in the process of strengthening the paleae.

A point of considerable scientific interest also emerges from these experiments. The panicles of first-cross plants show a remarkable range of variation in the types of spikelet carried. In addition to various intermediate forms, both the pure tight and the pure loose forms of paleae occur. Pure tights predominate on the lower central part of the panicle, but as one passes upwards, and also outwards, these tend to be replaced more and more by intermediate, and finally by the pure loose forms. Nevertheless, there appears to be no difference in the nature of the generation raised from the various types of grain which occur on these mixed panicles.

A second paper gives an account of an experiment to determine the heredity of early and late ripening in Oats. Of the two varieties chosen for crossing, Mesdag and Hopetown, the former ripens about three weeks earlier than the latter. In either case the ripening period is spread over about a fortnight, but there is no overlapping. Between the latest Mesdag and the earliest Hopetown there is a period of more than a week. First-cross plants proved to be intermediate in time of ripening between the parents. Owing to unavoidable circumstances the F_2 generation was not studied with care, though it was clear that very considerable differences occurred. But a careful study was made of the F_3 generation, which was raised from 106 F_2 plants. The results showed definite segregation. Two of the F_3 families were as early as Mesdag, and Mr. Caporn concludes that the results can be interpreted on the assumption that three definite Mendelian factors are concerned with the time of ripening in this cross. With regard to the possible improvement of early varieties, he offers some interesting suggestions, which may be reproduced here. "There can be little doubt that the extent of the tillering has much to do with the rate of ripening. The tillering power of late forms is always good; that of early, very poor. Owing to the concentration of growth among early plants into one or two panicles only, these are generally bigger and bear better grain than those of late plants; but this advantage does not compensate for the diminished yield due to the small number of heads. There is thus an inevitable sacrifice of crop when it is attempted to render a late kind early. The only hope, apparently, lies in increasing the output, per individual panicle, of an already early variety. This can best be done by extracting it again from a fair-sized F_2 generation of a cross with a type which, quite apart from any ability to tiller profusely, has above all larger panicles and larger grain of better quality."

Mr. Caporn's third paper deals with the results derived from a cross made between Polish Wheat (Triticum polonicum) and an Abyssinian variety (T. etobonii). The latter differs in many respects from T. polonicum, but the study is confined to the inheritance of glume length and of grain colour. In T. polonicum the glume is long and the grain uncoloured; in the Abyssinian variety the glumes are short and the grain is purple. The inheritance of glume length brought out an interesting feature. On first-cross plants the length is intermediate. F_2 plants show a range of variation. In some the glume length is definitely long and in others as definitely short, but in most it is more or less intermediate. Further analysis made by growing an F_3 from 183 F_2 plants brought out a definite 1:2:1 ratio of longs, intermediates, and shorts. One-quarter bred true to long glumes and one-quarter to short glumes, the remainder giving a mixture. But of the longs none was as long as T. polonicum, and of the shorts none was as short as T. etobonii. As the author remarks: "Along with the ordinary segregation there is established in the F_2 generation a kind of telescopic effect, whereby the means of the two homozygote curves are brought nearer to that of the heterozygotes than the means of the parents would actually be. This condensation persists right through into the F_3 generation, in which, owing to the possibility of isolating the 'pure long' and 'pure short' curves, it can be the more readily observed. There is thus every indication that this slight change in regard to the average glume length of extracted pure types as compared with the parents is a permanent one."

The results recorded for grain colour are complex. In addition to coloured and non-coloured grains, there also occur particoloured grains with streaks of pigment. Any one of these three classes may be got to breed true. Only a small proportion of the coloured and streaky plants do so, the majority giving either two of the three kinds, or all three of them in various proportions. In his treatment of the data the author brings out a semblance of orderliness, but he admits that they are not sufficiently full to justify the framing of a scheme of inheritance for them. Nevertheless, it is an interesting addition to that growing group of cases of variegation, of which the heredity appears to offer special problems of its own. The demonstration of this peculiar type of heredity in a plant of such high economic importance as Wheat will serve to enhance the value of studies in other plants where similar phenomena occur.

* *Journal of Genetics*, Vol. VII., Pt. 4, Aug., 1918.

Itea ilicifolia.—As a garden plant Itea ilicifolia must be classed with the Chinese curiosities, of which a considerable number have revealed themselves among the hosts of plants introduced from the Far East in recent years. It is inferior to the American I. virginica, because its flowers are greenish white, not white, neither are they fragrant, and superior in the length of its tail-like racemes, which sometimes are 1 foot long. The Holly-like leaves of the Chinese plant may also be considered a recommendation, seeing that the genus belongs to the Saxifraga order. The illustration at fig. 58 shows a plant in flower against the south wall of a warm greenhouse at Kew, for it is not hardy there, though it may prove to be hardy in warmer districts. The plant was discovered in Hubeng by Dr. HENRY, and first flowered in this country in Lord KESTEVEN'S garden at Casewick in 1885.

Women's Farm and Garden Union.—This admirable institution was established six years ago by Miss ALICE CAZALET, and has been doing splendid work during the present year. Its object is to train women who are bona fide workers and whose acceptability is vouched for by reliable sponsors.

Conference of Horticultural Lecturers at Wisley. A second conference of lecturers on allotment gardening, under the auspices of the Royal Horticultural Society's Food Production Scheme, was held at the Society's Gardens, Wisley, from September 25 to October 2 last. The leaders of the conference were Mr. F. J. CHITTENDEN, head of the R.H.S. Laboratory and School of Horticulture; Mr. J. C. NEWSHAM, principal of the Monmouthshire Farm School, Usk; and Mr. A. G. BRIGGS, Instructor in Horticulture to the Surrey County Council. The following attended the conference:—Mr. F. JENNINGS, Chatsworth Gardens; Mr. R. W. GREEN, Strathmore, Elm, Walsall; Mr. H. BIRD, Battenburg Avenue, Leicester; Mr. A. D. GROUND, Ilchester, Welshpool; Mr. J. G. BLAKEY, The Gardens, Hollywood, Redditch; Mr. H. PATIENCE, Waddeler Lane, Cheltenham; Mr. H. ASHFORD, The Gardens, Aberdeen, near Abergavenny; Mr. A. GIBSON, Hedrington Hill Hall Gardens, Oxford; Mr. A. C. BARTLETT, The Orchard, Hampton Hill; Mr. H. COWLEY, 7 The Gardens, 29, Haystock Street, W.C. 2; Mr. J. B. STEVENSON, China Garden Cottage, Bournemouth; Mr. G. WHITTINGHAM, The Gardens, South Down Hall, Polegate; and Mr. H. STADMAN, The Nurseries, Crawley. The object of the conference was to ensure uniformity of advice on the various gardening operations.

Nova Scotia Apple Crop. Estimates place the yield of the Nova Scotia Apple crop at from 400,000 to 500,000 barrels. That conditions on the whole have been rather unfavourable is shown by the fact that an average year disappointingly matures 500,000 to 1,000,000 barrels. Last year the crop amounted to 650,000. This in 1911 1,400,000 barrels were produced by the orchards of Nova Scotia. Although the yield as estimated is below normal, Nova Scotia fruit growers must find a market outside of the province for 300,000 barrels.

War Items.—Pte. C. W. C. YOUNG, eldest son of Mr. W. H. YOUNG, formerly of Care Lawn Gardens, East Sheen, and now in charge of the Orchids at Warren House, Stanmore, after passing safely through the many dangers of two years and nine months' campaign in France, was, we regret to learn, killed in action on the 2nd inst. He joined the Civil Service Rifles, 1/15 London, in May, 1915, when he was just seventeen, and thus has added his name to the roll of honour ere he reached his 21st birthday. Before joining the Army he was a member of the staff of the Great Eastern Railway at Bishopsgate.

With deep regret we learn that Mr. ARCHIBALD COKE, late of Biel Gardens, East Lothian, and formerly foreman gardener at Roby Hall, Tarbolton, was killed in action on July 20, after two years and nine months' service in France.

cially for women war workers on the land in conjunction with the Women's National Land Service Corps. It is affiliated to the National Union of Women Workers, the Herb Growers' Association, and other bodies interested in the welfare of women. The president is Princess LOUISE, Duchess of Argyll and members of the council include Lady FALMOUTH, Lady NORTHCOTE, the Countess of SELBORNE, Miss WILLCOCKS, and other influential persons, while Mr. PROTHERO, Professor BIFFEN, Professor BOTHAMLEY and Professor WOODHEAD are members of the Advisory Committee. The office is at 50, Upper Baker Street, and the secretary, Mrs. MILES BENSON, is most energetic and disinterested in affording assistance and advice to women desirous to work at farming or gardening and to employers in want of expert assistance. A Monthly Leaflet is issued containing useful information. An excellent club for women has been started, membership being limited to those who are bona fide workers and whose acceptability is vouched for by reliable sponsors.

Conference of Horticultural Lecturers at Wisley. A second conference of lecturers on allotment gardening, under the auspices of the Royal Horticultural Society's Food Production Scheme, was held at the Society's Gardens, Wisley, from September 25 to October 2 last. The leaders of the conference were Mr. F. J. CHITTENDEN, head of the R.H.S. Laboratory and School of Horticulture; Mr. J. C. NEWSHAM, principal of the Monmouthshire Farm School, Usk; and Mr. A. G. Jam Rationing. Jam, marmalade, syrup, treacle and honey are to be rationed from November 3. Purchases of jam and marmalade can be made only from the retailer with whom the consumer is registered. Syrup, treacle, and honey may be bought with coupons from any retailer able to supply them. Persons who will be between the ages of six and eighteen at midnight on December 31 can obtain a supplementary ration of jam. They will receive a book containing an extra leaf of red coupons with a jam counterfoil, which must be registered. In addition to providing for the licensing of wholesale dealers in jam or syrup, the Jam and Syrup (Registration of Dealers) Order also makes obligatory the registration of retailers of jam or syrup. Applications for registration by such retailers should be made not later than October 15 to the Food Control Committee of the district in which the retailers' premises are situated.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Apple Small's Admirable.—As a kitchen Apple I regard Small's Admirable as one of the very best sorts, though, for some unexplained reason, it is very little grown. It is one of the most reliable varieties, in fact our trees have never failed to crop fully for the past 30 years, and this season, when Apples are generally scarce, it has proved to be our best. On October 2 we picked 16 bushels from one tree. In appearance the fruit much resembles Tower of Glamnis, and about equals it in quality. In growth it is quite distinct, having a much more pendulous habit, and, indeed, it is one of the most attractive Apple trees I know. *E. Beckett, Aldenham House Gardens, Elstree.*

Perpetual-Flowering Carnations in Unheated Greenhouses (see p. 127).—The majority of Carnation growers will agree with *A. H.* that artificial heat is not necessary to protect these plants from frosts during the winter, just as the great consensus of opinion would disagree with the statement that "no plant will produce such generous supplies of bloom during the entire twelve months of the year as the Perpetual Carnation when grown without artificial heat." None more than the great Carnation specialists of England and America—the men who cover countless acres with glass for the cultivation of the Carnation alone—would welcome and adopt such a course were it practical and sound, since it is "generous supplies of bloom during the entire twelve months of the year" that they are out for, and since also the saving in fuel, labour and appliances would be very great. Artificial heat for the Perpetual-flowering Carnation in winter-time is not necessary in order to counteract cold alone, least of all dry, frosty cold, though it is essential and absolutely necessary in the case of flowering plants in order to assist the development of the blooms, in conjunction with a free circulation of air to dispel damp, which is the greatest enemy to be overcome in low-lying districts, and the precursor of much disease. Without artificial heat the flowers would but damp and rot upon the plants. Chief of the drawbacks to the successful flowering of the Carnation in England in winter are damp, fog, and absence of sunshine, and while the cultivator is helpless in the case of the two last-named, he can, at least to some extent, lessen the evils arising from the first by a discreet use of fire heat as experience dictates. *E. H. Jenkins.*

SOCIETIES.

ROYAL HORTICULTURAL.

OCTOBER 8.—The London Scottish Drill Hall, Westminster, was well filled with exhibits of fruit on Tuesday last, and a large number of Fellows and visitors attended the meeting. The Floral Committee did not meet on this date, nor did the Orchid Committee meet, as the whole meeting was given over to displays of British-grown fruit. The Joint Committee of the R.H.S. and National Dahlia Society met early in the morning to consider new Dahlias submitted for awards.

The Fruit Show was a great success, and the quality of the fruit staged was amazingly fine, while the quantity was far greater than the most optimistic visitor anticipated.

Fruit and Vegetable Committee.

Present: Messrs. A. H. Pearson (in the chair), J. Cheal, W. Poupart, John Harrison, W. Pope, E. W. Roach, W. Bates, Edwin Beckett, G. Reynolds, A. R. Allan, W. Crump, H. Hooper, H. Markham, N. F. Barnes, Thos. Coomber, A. Bullock, F. Jordan, Jas. Gibson, J. G. Weston, E. A. Bunyard, W. H. Divers, John Basham, P. C. M. Veitch, Geo. P. Berry, H. S. Rivers and P. D. Tuckett.

A few seedling Apples were forthcoming, but no award was made. One named Cutler Grieve, raised by Mr. Jas. Grieve, and shown by Messrs. G. Bunyard and Co., the Committee desired to see again. Well-cropped Production Runner Beans, shown by Mr. J. Cook, Camberley, attracted some attention; large clusters of fleshy pods were borne on plants raised from seeds sown about the middle of June.

Competitive Fruit Classes.

The competition in the various classes for fruits was fairly good throughout, and especially in those for Grapes.

Apples were wonderfully fine in size and colour, and the comparatively few Pears staged were of excellent size and quality.

Collections of Dessert Fruits.

Nine Dishes of Ripe Dessert Fruit.—There were three exhibitors, and all staged very creditable collections. The 1st prize was won by C. A. Cain, Esq. (gr. Mr. J. Pateman), The Node, Welwyn, for a splendid collection in which every kind reached a high stage of perfection. Muscat of Alexandria and Madresfield Court Grapes, Superlative Melon, Sea Eagle and Late Admirable Peaches, Durondeau and Doyenné du Comice Pears, and Cox's Orange and Ribston Pippin Apples were all shown well; 2nd, The Duke of Newcastle (gr. Mr. G. Barker), Clumber, Worksop, whose outstanding dishes were of Muscat Hamburgh Grapes, Princess of Wales and Golden Eagle Peaches and Pitmaston Pine Apple; 3rd, Mr. James Lock, Oatlands Lodge Gardens, Weybridge.
